the only mineral of economic consequence. It forms 80% by value of Surinam's exports, and the territory is among the world's chief sources of the mineral.

The other principal exports are plywood and rice. Imports, chiefly machinery, fuel oil, construction materials, and foodstuffs, are mainly from the U.S. and the Netherlands. Local industries are numerous but small. They include logging, rice mills, and a modern clothing industry.

A ten-year plan, launched in 1955, envisaged the expenditure of 117 million Surinam guilders (later raised to 207 million Surinam guilders) on agriculture, industry, communications, education, and social services. The plan accomplished much in its efforts to make Surinam more independent economically. Schemes successfully completed included the Afobaka-Brokopondo project already mentioned; the reconstruction of irrigation works; the reclamation of new land; housing; a complete geological survey; and a number of new roads.

The currency unit is the Surinam guilder (gulden or florin; 1.89 Surinam guilders = U.S. \$1). The Centrale Bank van Suriname, established in 1956, is government sponsored and acts as a clearing house, supervising the monetary system. In addition there are several commercial banks and a number of investment and mortgage banks.

In spite of modern improvements the road system remained inadequate. There were in the mid-1960s about 975 mi. (1,569 km.) of "all-weather" roads, of which about 290 mi. (466 km.) were asphalted and the rest topped with shell and bauxite. The main east-west road, 220 mi. (354 km.) from Albina on the Maroni (Marowijne) to Nieuw Nickerie on the Courantyne (Corantijn), was completed in 1965. The main north-south road in the mid-1960s was asphalted for 18 mi. (29 km.) from Paramaribo to Paramam, and continued an additional 45 mi. (72 km.) with a bauxite surface to Afobaka.

The other main road extended 28 mi. (45 km.) from the capital to Zanderij airport. The airport, one of the best in the Caribbean area, maintained international and domestic services. There was one single-track railway, from Paramaribo to Republiek, Zanderij, and Kabelstation (83 mi., 133 km.).

Internal transport depended heavily on waterways. A singularly complete system on the coastal plain required only the single artificial link of the Saramacca Canal to provide a through waterway from the east to the west border of the country. Paramaribo, which has more than 2,000 ft. (609 m.) of wharf, has regular sailings to Caribbean, U.S., and European ports.

**SURINAM TOAD**, a tongueless, tailless amphibian unusual in several respects. It is *Pipa pipa* (or *P. americana*), one of several species of the family Pipidae. It inhabits South America east of the Andes and north of the Amazon and is strictly aquatic, feeding largely on fish in quiet pools. It has a flat body and an extremely flattened head. The snout and the angles of the jaws bear several loose skin flaps, the fingers of the forelimbs terminate in small star-shaped appendages, and the eyes are minute and without lids. The hind limbs end in large fully webbed feet.

These toads exhibit a remarkable method of mating and parental care. Pairing takes place in the water, the male clasping the female round the waist. During oviposition the female extends from the cloaca a long bladderlike pouch, which the male carries forward between his breast and the gelatinous-covered back of the female. As each egg is released, it is fertilized and attached by a natural adhesive to the female's back. The skin thickens and grows round the eggs until each is enclosed in a dermal cell, which is finally covered by a horny lid. The eggs may number about 100 and measure 5–7 mm. in diameter. They develop for about 80 days entirely within these pouches, and the young hop out as miniatures of the adult.

**SURKHAN-DAR'YA**, an *oblast* of the Uzbek Soviet Socialist Republic, U.S.S.R., is bordered south by the Amu-Darya (Oxus River), which forms the frontier with Afghanistan. Area, 8,031 sq.mi. (20,800 sq.km.). Pop. (1959) 919,348, of which more than 15% is urban. In the centre and south is an upland plain bordered east, north, and west by mountains rising to 17,000 ft. (5,180 m.). The climate is continental with very hot summers (July average 21.9° C [71.6° F]). There are two towns, Termez (*q.v.*), the capital, and Denau. The economy is mainly agricultural, based on cotton in the irrigated valleys of the Surkhandar'ya and Shirabad, wheat on the hillsides, and the raising of karakul sheep and goats in the plains. (G. E. Wr.)

**SURMA** (BARAK), a river of Assam, India, and East Pakistan. It rises in the Barail Range in the union territory of Manipur, in northeast India, its source being among the southern spurs of Mt. Japvo. Thence its course is south, with a slight westerly bearing, through the Manipur Hills. The name "Barak" is given to the upper part of the river, in Manipur and the Cachar district of Assam. A short distance below Badarpur in Cachar it divides into two branches, which then flow into East Pakistan. The northern, which passes Sylhet, is called the Surma. The southern, called the Kusiara, subdivides into two branches, one called the Bibiyana or Kalni, and the other the Barak, both of which rejoin the Surma. At Bhairab Bazar, in the Mymensingh district of Dacca, the Surma unites with an old channel of the Brahmaputra and becomes known as the Meghna until it joins the Ganges between Narayan-ganj and Chandpur. The river is navigable by steamers as far as Silchar in the rainy season. The total length is about 560 mi. (900 km.). (L. D. S.)

**SURPLICE**, a liturgical vestment of the Christian Church. It is a loose tunic of white linen or cotton material, with wide sleeves, worn as a choir vestment in the Roman Catholic Church (in which it is proper to all clerics) and as a eucharistic vestment in the Anglican Church and in some Lutheran and Free churches. The surplice appeared first in the Middle Ages, and it has no counterpart in the Eastern Churches. See VESTMENTS, ECCLESIASTICAL.

**SURREALISM**, a widespread revolutionary movement in the arts, promoted by the poet André Breton. The word itself was coined by the poet Guillaume Apollinaire, and the movement had its heyday, primarily in Paris, from 1918 to 1939, attacking tradition in all forms. It was an assertion of the belief that the world of the unconscious mind—as expressed by fantasies and dreams—has a reality superior to that of the phenomenal world. Surrealist expression aimed at a creative integration of both realities into a "super-reality." The theory owed much to the research of Sigmund Freud, whose technique of probing the unconscious mind for the ultimate truth of human behaviour compares with the surrealist method of penetrating the depths of human personality

to tap the inexhaustible sources of the imagination. In *Manifeste du surréalisme*, published in 1924 in Paris, Breton's own definition of surrealism was: "Pure psychic automatism, by which it is intended to express whether verbally or in writing, or in any other way, the real process of thought. It is the dictation of thought, free from any control by the reason and of any aesthetic or moral preoccupation."

Submission to mental promptings, appropriate as means of spontaneous writing, could apply only to the initial, conceptual phase of a painting. Since the movement was largely a literary expression, surrealist painting was, therefore, an illustrative art based on literary themes, using realistic and recognizable means and expressions. In abandoning rational, moral, and aesthetic considerations, it echoed Dadaism (*q.v.*); but it was dissimilar in having a positive intention, namely to create a new, authentic vision of life by releasing dormant sensibilities. The release found infinitely varied expression in a fantastic art which, unprecedented as a movement, had affinities with the weird images of individual painters like Hieronymus Bosch (*q.v.*) or Giuseppe Arcimboldo. The emergence of surrealism in art was assisted directly by such notable pioneers as Kurt Schwitters, whose collages established strange relationships between disparate objects in juxtaposition; Marcel Duchamp (*q.v.*), whose "ready-mades" revealed the extraordinary significance of objects in abnormal contexts; and indirectly by Giorgio de Chirico, Paul Klee, and Pablo Picasso (*qq.v.*). Exponents of surrealist art were Hans Arp, Salvador Dalí (*q.v.*), Paul Delvaux, Jean Dubuffet, Matta Echaurren, Max Ernst, Morris Graves, René Magritte, André Masson, Joan Miró (*q.v.*), Francis Picabia (*q.v.*), and Yves Tanguy.

Surrealist expression also found outlet in literature (Jean Cocteau, Paul Éluard, Guillaume Apollinaire [*qq.v.*], and Louis Aragon), in sculpture (Alberto Giacometti), and in photography (Man Ray). The spirit of surrealism is also to be seen in advertising techniques where objects apparently unrelated are juxtapositioned.

**SURREY, EARLS AND DUKE OF.** The English title of earl of Surrey was created in the 11th century and since 1483 has been held by the Howards, earls and dukes of Norfolk. **WILLIAM DE WARRENNE** (d. 1088), a Norman baron who fought with William the Conqueror at Hastings in 1066, was created earl of Surrey by William II in 1088. His immediate successors were generally known as earls de Warrenne (for the earls of the Warrenne family see **WARRENNE**). On the death without issue of **JOHN DE WARRENNE** (1286–1347), 8th earl, the title passed to his nephew **RICHARD FITZALAN** (c. 1313–76), 3rd earl of Arundel, the son of Edmund Fitzalan and Alice, sister of the 8th earl. Richard styled himself earl of Surrey in 1361 on the death of his aunt, the dowager Countess Joan. The title was forfeited when Richard's son **RICHARD** (1346–97), 10th earl of Surrey and 4th earl of Arundel, was beheaded for conspiring against Richard II (see **ARUNDEL, EARLS OF**).

**THOMAS DE HOLAND** (c. 1371–1400), earl of Kent, was created duke of Surrey in 1397 for supporting Richard II against the lords appellant (see **ENGLISH HISTORY**). He was degraded from the dukedom and forfeited the title in November 1399 and was beheaded in January 1400 for conspiring against Henry IV. The earldoms of Surrey and Arundel were restored in October 1400 to **THOMAS FITZALAN** (1381–1415), son of the 10th earl, but on his death without issue the Surrey earldom reverted to the crown. **JOHN MOWBRAY** (1444–76), son of John (1415–61), 3rd duke of Norfolk of his line, was created earl of Surrey in 1451, but the title again became extinct on his death. It was revived in 1483 for **THOMAS HOWARD** (1443–1524), son of John (c. 1430–85), 1st duke of Norfolk of his line. The title has since been held by the Howard family (see **NORFOLK, EARLS AND DUKES OF**). The present holder of the title is **BERNARD MARMADUKE FITZALAN-HOWARD** (1908– ), 16th duke of Norfolk.

**SURREY, HENRY HOWARD, EARL OF** (1517–1547) English poet who, with Sir Thomas Wyatt (*q.v.*), introduced into England the styles and metres of the Italian Humanist poets and so laid the foundation of a great age of English poetry. He was born early in 1517, perhaps at Hunsdon, Hertfordshire, the grandson of Thomas Howard, earl of Surrey and duke of Norfolk, who defeated the Scots at Flodden in 1513; and the eldest son of Lord Thomas Howard. In 1524, when his father succeeded as 3rd duke of Norfolk, he took the courtesy title of earl of Surrey.

HENRY HOWARD, EARL OF SURREY: PORTRAIT BY HANS HOLBEIN THE YOUNGER, DRAWN AFTER 1532

In his early years Surrey was influenced by the Humanist John Clerk and learned Italian as well as Latin. From 1530 until 1532 he lived at Windsor with his father's ward, the bastard son of Henry VIII, who had been created duke of Richmond in 1523. After talk of a marriage with the princess Mary, in April 1532 he married Lady Frances de Vere, the 14-year-old daughter of the earl of Oxford; they did not live together until 1535. [In October 1532 he went with Richmond to the Field of Cloth of Gold and then to the French court, where his behaviour seems to have been free from the rashness and occasional boasting that marked it later.] Despite his marriage and alliance between him and the princess Mary was still discussed. It was Surrey's fate, because of his birth and connections, to be constantly, though usually peripherally, involved in the jockeying for place that accompanied Henry VIII's policies. In 1533 Richmond married Surrey's sister Mary, but the two did not live together, and Richmond's death in 1536 postponed the trouble that was to come of this connection.

In 1537, however, Surrey was confined at Windsor after being charged by the Seymours (high in favour since the king's marriage to Jane Seymour in 1536) with having secretly favoured the Catholics in the rebellion of 1536 known as the Pilgrimage of Grace. He had in fact joined his father against the insurgents (see **NORFOLK, THOMAS HOWARD, 3rd duke of**), and in anger struck his accuser. His punishment for breaking the peace ended in 1539. In May 1540 he was a champion in court jousts, and in August his prospects were further improved by the marriage of his cousin Catherine Howard to the king. Though he was imprisoned in 1542 for quarreling, and for breaking Londoners' windows with Thomas Wyatt the younger in 1543, these confinements were short and he was free to serve in the campaign in Scotland in 1542 and in France and Flanders from 1543 to 1546. He showed something of his grandfather's military abilities, acted as field marshal in 1544, and won royal approval.

This was the end of his period of favour. Returning to England in March 1546, he found the king dying and his old enemies the Seymours further incensed against him by his interference in the projected alliance between his sister the duchess of Richmond and Sir Thomas Seymour; he made matters worse by his assertion that the Howards were the obvious regents for Prince Edward. The Seymours, alarmed, accused Surrey, with his father, of treason and called the duchess of Richmond to witness against him; Surrey was said to have quartered the arms of Edward the Confessor on his own. He defended himself unavailingly and was executed at Tower Hill on Jan. 19, 1547. His father was saved only because the king died before he could be executed.

No historical credence can be given to the account in Thomas Nashe's *The Unfortunate Traveller* (1594) and Michael Drayton's *Englands Heroicall Epistles* (1598) of Surrey's love for Lady Elizabeth Fitzgerald. She was the "Fair Geraldine" of his love poetry, but she was a child when he wrote about her, and the likelihood is clearly a fanciful creation on the ground of an interest in her charm.

Most of Surrey's poetry was probably written during his confinement at Windsor; it was nearly all first published in 1557. He acknowledged Wyatt (on whom he wrote an epitaph) as a master, and certainly followed him in adapting Italian forms to English verse. He translated from Petrarch a number of sonnets already translated by Wyatt, and a comparison of their translations shows that Surrey achieved a greater smoothness and firmness, qualities that were to be important in the evolution of the English sonnet (*q.v.*). Surrey was the first to develop the form used by Shakespeare. His smoothness often degenerates into monotony, but at least one sonnet, "The soote season," is memorable for its sweet fresh grace.

His other short poems have less intensity and metrical subtlety than most of Wyatt's but are remarkable in ranging over a wider field of emotional experience than most poetry of the time. He writes not only on the usual early Tudor themes of love and death but also a satire on London, and of friendship, and musing memories of happy youth. Emotion is freshly conveyed when "Prisoned in Windsor, he recounteth his pleasures there passed":

So cruel prison how could betide, alas,  
As proud Windsor? where I in lust and joy,  
With a king's son, my childish years did pass,  
In greater feast than Priam's sons of Troy.

The love poems have little force except when, in two "Complaint(s) of the absence of her lover being upon the sea," he writes, unusually for his period, from the woman's point of view:

When other lovers in arms across,  
Rejoice their chief delight,  
Drowned in tears to mourn my loss  
I stand the bitter night  
In my window where I may see  
Before the winds how the clouds flee.  
Lo, what a mariner love hath made me!

The short poems were printed by Richard Tottel in his *Songes and Sonettes written by the ryght honorable Lorde Henry Haward, late Earle of Surrey and other* (1557; usually known as *Tottel's Miscellany*). "Other" included Wyatt, and critics from George Puttenham (*q.v.*) onward have coupled their names.

In the same year *Certain Booke of Virgiles Aeneas* was published, and this translation of Books II and IV of the *Aeneid* marks the first use of blank verse (*q.v.*) in English. Surrey adopted the metre from Giangiorgio Trissino and others, but the importance of its introduction into English cannot be overestimated. The actual writing is often stiff in phrasing and syntax, but it established what was to become the staple metre for long poems in English, developed with infinite richness and variety by the greatest poets.

**BIBLIOGRAPHY.**—*Editions:* Surrey's *Works*, ed. with those of Wyatt, by G. Sewall (1717), and by G. F. Nott, 2 vol. (1815–16); with those of Sackville and others by R. Bell (1854); and by F. M. Padelford (1920, rev. ed. 1928), and E. Jones (1964). Shorter poems in G. Bulllett (ed.), *Silver Poets of the XVth Century* (1947). *Aeneid IV*, ed. by H. Hartmann (1933); *The Aeneid of Henry Howard Earl of Surrey*, ed. by F. H. Ridley (1963).

Willcock, on the Aeneid version, in *Modern Language Review*, xiv, xv, xvii (1919–22); E. Casady, *Henry Howard, Earl of Surrey* (1938); Hester W. Chapman, *Two Tudor Portraits* (1960). (C. M. I.)

**SURREY**, a southeastern county of England, is bounded on the northeast by Greater London, east by Kent, south by Sussex, west by Hampshire, and northwest by Berkshire and Buckinghamshire. The area of the administrative county is 649.8 sq.mi. (1.683 sq.km.) and comprises 4 boroughs, 14 urban districts, and 5 rural districts.

The north of the county adjoining the Thames is low lying, and the soil consists largely of brick earth overlying London Clay. To the west, on the edge of the Thames Basin, Bagshot Sands outcrop at Chobham Common, and Bagshot Heath and Chobham Ridges (400 ft. [122 m.]) are capped by plateau gravels. Across the middle of the county, from east to west, run the chalk North Downs. In the east they form a wide band, rising to a height of 852 ft. [260 m.], but westward they narrow into the Hog's Back.

The line of the Downs is broken by the River Mole between Dorking and Leatherhead, and by the Wey at Guildford. These are the county's two chief rivers, and they join the Thames at Molesey and Weybridge, respectively. To the south of the chalk Downs is a wide band of Lower Greensand, which narrows eastward: On this greensand is found the highest land in the county, Leith Hill (965 ft. [294 m.]) near the centre, and Hindhead (895 ft. [273 m.]) in the west. The rest of the county, except for a small triangle of Hastings Beds in the extreme southeast, is composed of Weald Clay. The National Trust owned 11,798 ac. (4,774 ha.) in Surrey and protected 586 ac. (237 ha.) in 1964. In 1958 about 160 sq.mi. (414 sq.km.) in the Surrey Hills was established as "an area of outstanding natural beauty" under the National Parks and Access to the Countryside Act, 1949. At Wisley are the gardens of the Royal Horticultural Society.

**History.**—This discussion embraces certain places once in Surrey but now in Greater London (for boundary changes *see* below).

Paleolithic implements were found in the gravel beds of the Wey, the Mole, the Wandle, and the Thames (for example, near Farnham, Guildford, Godalming, Mortlake, and Wandsworth), and at older gravel plateaus, such as Warlingham and Wimbledon Common. At Blackheath near Albury there is evidence of Neolithic man. Hoards of bronze implements have been found at a number of places. Iron Age earthworks cover a wide area and include mounds at Weybridge, Farnham, Holmbury, and one, the largest of all, near Lingfield.

It was an area of forest, swamp, heath, and open downland through which the Romans passed at the time of the invasion of Julius Caesar (55 B.C.), using perhaps the ancient track along the Downs, later known as the Pilgrims' Way. Romanization, however, did not come until the time of the emperor Claudius I (A.D. 43). For the next four centuries Surrey was ruled by the Romans, and though Roman remains are relatively few, the largest settlements appear to have been at Southwark, Kingston upon Thames, Farley Heath near Albury, and Woodcote near Croydon. Remains of about two dozen villas lie, for the most part, along the northern and southern edges of the Downs and include that of Ashted to the north and Titsey to the south. The Thames was bridged at Southwark as part of Watling Street, leading from Dover and Canterbury. Stane Street, from Chichester to London, was probably not constructed till the 3rd century; it ran via Ockley, Dorking, and Merton. No Roman town survived the Saxon settlement of Surrey, and there are few place-names of Roman origin. Surrey was never an independent Saxon kingdom. The name itself means southern district. Nearly all place-names are of Saxon origin, a large proportion pagan, such as Friday Street (commemorating the goddess Frigg [Frea]). The scantiness of the population is indicated by the small number of hundreds (14) compared with neighbouring counties. The tithings into which they were divided generally became parishes after the establishment of Christianity. Coronations of West Saxon kings at Kingston during the 10th century are referred to by chroniclers. A coronation stone is preserved there.

During the reign of Edward the Confessor, Godwin, earl of Wessex, and members of his family, including Harold, held many manors in Surrey. After the Battle of Hastings (1066) William I took these for himself or for his Norman followers. Held back in Southwark from entering London, he turned southward to the Pilgrims' Way. Domesday Book shows the extent of the ravaging of the Normans through Limpsfield, Godstone, and Gatton, and then westward through Albury, Shalford, and Farnham along the road to Winchester. The bishop of Winchester retained Farnham.

Chertsey Abbey, according to the 13th-century cartulary, was founded in 666 by St. Erkenwald, who became its first abbot. It was burned during the Danish wars (c. 871). Refounded for Benedictines in the 10th century, it maintained a prominent position and held many manors, including Chertsey, Egham, Thorpe, Chobham, Cobham, Epsom, Sutton, and Coudsdon, until it was dissolved in 1537. Later foundations include the Cluniac priory of Bermondsey (1082), the Cistercian abbey of Waverley (1128), the Augustine priories of Merton (1117), Newark (c. 1190), Tandridge (c. 1200), and Reigate (1220).

Even in the 13th and 14th centuries there probably was a strong contrast between the outlying forests and the suburban parts of Surrey, Southwark, Lambeth, and Bermondsey, with their great suburban houses of ecclesiastical dignitaries, sharing in the life of London. Kingston, with its bridge over the Thames, was a market town, as was Guildford with its manufacture of cloth. As elsewhere the ravages of the Black Death intensified commercial depression and religious agitation, which led to the Peasants' Revolt of 1381.

Sheen already had royal importance when Richard II pulled down the palace after the death of his first queen. Henry V rebuilt it, founding at the same time a Carthusian house. Following the insurrections of the 15th century, Surrey under the Tudors became a county of royal residences. Henry VII rebuilt the palace of Sheen, renaming it Richmond. Henry VIII and Elizabeth I resided there, and Henry VIII received Hampton Court, just across the Thames, from Cardinal Wolsey. This brought court officials to the villages on the Surrey side. After the dissolution of the monasteries (1536-39), Henry built a flamboyant hunting lodge in Surrey, Nonsuch (near Ewell). This was built partly of materials from the dissolved priory of Merton and on the site of the village of Cuddington, which he destroyed. Stones from Waverley Abbey were used in building Loseley House, and Oatlands Palace (Weybridge), now in ruins, had stones from Chertsey Abbey. The manors of the religious houses fell into the king's hands or were sold by him or his successors. Reigate Priory was granted to William Howard (later Lord Howard of Effingham; see HOWARD); and his son, who was commander in chief against the Spanish Armada (1588), is buried in Reigate Church. No reference to the Tudors could ignore the theatres of Southwark, more especially Shakespeare's Globe.

In the Middle Ages sheep were important in rural Surrey, and by the 16th century a cloth trade was growing, for example, at Guildford, Godalming, and Farnham. Fuller's Earth was already known at Nutfield and until the 19th century was used mainly in the woolen industry. In the 16th century iron smelting with charcoal in the Weald areas was further developed because of the demand for cannons. Charcoal was also needed to make gunpowder. Powder mills were established before 1570 at Rotherhithe, Wotton, Albury, and Chilworth (the latter closed only during World War I), and at Godstone in 1589. Glassmaking at Chiddingfold flourished until the beginning of the 20th century; it may have begun during the Roman occupation.

Surrey, like London, was overwhelmingly parliamentary during the Civil War. It was not a major battleground, though there was fighting in the county, for example during the Royalist reversals leading to the stand at Kingston Common (July 7, 1648).

By 1653 the canalization of the Wey from Guildford to the Thames, planned by Sir Richard Weston of Sutton Place, was completed. This facilitated the transport to London of timber, grain, iron, gunpowder, and the produce of market gardens. Daniel Defoe in the early 18th century described Farnham as the greatest corn market in England, London excepted, grain being brought along the Wey to be ground and sent onward to London by water.

Surrey quarter sessions records that survive from 1659-60 contain numerous references to Quaker meetings and religious dissent generally. At the July sessions, 1665, during the plague, it was ordered that the wells at Epsom be locked for the summer to discourage visitors from London and thereby prevent the spread of disease. Samuel Pepys and John Evelyn, both Surrey men, have many references to the county in their *Diaries*, including Epsom at its height as a spa. It was then that horse racing on the Downs became fashionable. It was already possible to go from London for the day. John Evelyn was also a great gardener, expert on trees, and pioneer planter of conifers.

In Surrey much land was enclosed before the 18th century. Market gardens were a feature in the west and along the Thames, as at Mortlake, at Mitcham, with its lavender and physic gardens, in Bermondsey, and Camberwell. These gave place to housing developments. Godalming and Guildford declined as industries moved to the Midlands or to Yorkshire. Maps of the 18th and 19th centuries show copper, iron, oil, grain, paper, snuff, and calico

printing mills, mainly along the Wandle. Elsewhere were chalk gravel, and stone quarries, brickworks, and lime kilns.

The middle decades of the 18th century saw the beginning of improved roads in Surrey, under turnpike trusts. Navigations included the improved canalization of the Wey as far as Godalming (1762); the Basingstoke Canal (1796), originally constructed to link the industrial town of Basingstoke with the port of London; and the Wey and Arun Canal (1816). The development of railways brought to an end the turnpike road system and canal building. The Surrey Iron Railway, from Wandsworth to Croydon and then to Merstham, worked by horses and intended to convey materials such as chalk and stone to the Thames, was the first public railway sanctioned by Parliament (1801). Freight was carried on payment of a toll. The first railway for steam trains to pass through Surrey was the London and Southampton, opened as far as Woking in 1838. This was followed by the London and Brighton in 1841. The railways brought the county, particularly north of the Downs, continually nearer to London and resulted in intense house building, as at Wimbledon, or at Caterham after the building of the Caterham Valley Railway, sanctioned in 1854.

William Cobbett (born at Farnham, 1763) in his *Rural Rides* observed political and social conditions in the 1820s. These must be viewed against the background of the wars with France and shortage of wheat. A wet summer and poor harvest helped intensify the crisis of the autumn of 1830. In 1848 the Chartist Rising ended at Kennington Common.

Until the 19th century the county lay in the diocese of Winchester, apart from those parishes belonging to Canterbury. In 1905 the diocese of Southwark was created. Parishes that had previously been transferred to the see of London and those that in 1877 had been transferred to Rochester were transferred to Southwark. In 1927 the west of the county passed to the new diocese of Guildford. Its cathedral, begun in 1936 and consecrated in 1961, stands on Stag Hill. It was designed by Sir Edward Maufe and contains sculpture by Eric Gill (d. 1940). Croydon remains in the diocese of Canterbury.

There are racecourses in the county at Epsom Downs, where "the Derby" is run, Sandown Park (Esher), Kempton Park, and Lingfield Park; the All England Lawn Tennis Club has its headquarters at Wimbledon; Bisley is a centre for rifle shooting; the headquarters of the Surrey County Cricket Club is the Oval in Kennington, Lambeth, but some matches are played at Guildford.

The development of the county has been greatly influenced by its proximity to London; its good transport facilities have made it attractive both as a residential and recreational area.

**Boundary Changes.**—The Reform Act of 1832 disfranchised three boroughs and divided the county into two divisions, each returning two members. Lambeth became a borough and was extended. Rotherhithe and Bermondsey were included in the borough of Southwark. Further changes were made by the Reform acts of 1867 and 1885. By the second act the boroughs of the northeast, including Southwark, Lambeth, and Croydon, were divided into 17 single-member districts. Apart from Croydon (which remained a county borough until 1965) these boroughs became in 1889 part of the new county of London and a new phase in the history of Surrey County, with its administrative headquarters at Kingston, began.

Until 1889, when the administrative counties (including London) created under the Local Government Act 1888 came into being, Surrey stretched along the south bank of the Thames as far east as Rotherhithe and embraced ancient parishes, including Wandsworth, Lambeth, Camberwell, and Southwark, which were in the hundred of Brixton, and under the act became a part of the administrative county of London.

Under the terms of the London Government Act 1963, the administrative county of London and most of Middlesex, with the addition of certain areas from adjoining counties, including Surrey, became Greater London on April 1, 1965. The county of Surrey was altered by the addition of the urban districts of Staines and Sunbury-on-Thames (from Middlesex) and the loss to Greater London of the boroughs of Barnes, Beddington and Wallington, Kingston upon Thames, Malden and Combe

Mitcham, Richmond, Surbiton, Sutton and Cheam, Wimbledon, and the urban districts of Carshalton, Coulsdon and Purley, and Merton and Morden. Croydon, the only county borough in Surrey, also became part of Greater London. The county's total area was reduced from 702 sq.mi. (1,818 sq.km.) (1961) to 649.8 sq.mi. (1,683 sq.km.). (See LONDON; CROYDON; MERTON; SUTTON; KINGSTON UPON THAMES; RICHMOND UPON THAMES.)

**Population and Administration.**—The population of the present administrative county (based on the 1961 census) was 902,691. The population of the 4 boroughs was: Epsom and Ewell 71,159; Godalming 15,780; Guildford 53,976; Reigate 53,751; of the 14 urban districts 2 had a population exceeding 50,000: Esher 60,610; and Woking 67,519. The 5 rural districts, one of which had a population exceeding 50,000, contained 69 civil parishes.

The headquarters of the Surrey County Council are at County Hall, Kingston upon Thames in Greater London. Assizes and quarter sessions are both held at County Hall. Guildford has separate sessions. There are magistrates courts for nine petty sessional divisions and also for the boroughs of Guildford and Reigate.

The northern part of the county (as far south as Epsom) is in the Metropolitan Police Area. The Surrey Constabulary, covering the rest of the county, is divided into eight divisions. The parliamentary constituencies in the administrative county under the Representation of the People Act 1948 (as amended) consist of nine county constituencies and parts of two others.

**Industries and Communications.**—The total acreage under crops and grass in the early 1960s exceeded 180,000 ac. (72,840 ha.), of which more than 110,000 were arable land. This represented about 25% of the total area (excluding water) of the county, compared with about 9% in 1939. Wheat and oats are the chief grain crops. The cattle are mainly of the dairy type. There are extensive market and nursery gardens in the fertile brick-earth plain beside the Thames and in the Bracklesham Beds at Chobham and Bagshot.

The level land adjoining the main roads and railways attracted groups of miscellaneous industries along the Kingston Bypass near Raynes Park and Tolworth, and also at Addlestone and Salfords. More recently there has been industrial development at Camberley. Kingston upon Thames and Weybridge are important centres of general engineering and aircraft industry, while miscellaneous industries in the Wandle Valley at Mitcham, Merton, and Hackbridge are the modern development of the old watermill industries for which the Wandle was once well known.

The main roads from London to Penzance, Portsmouth, Brighton, and the south coast pass through Surrey, which is served also by the Southern Region main and suburban lines of British Rail. The London Underground extends to Morden, Wimbledon, and Richmond. Bus and coach services cross the county. The civil airport at Gatwick was opened in 1958.

**SURTEES, ROBERT SMITH** (1805–1864), English novelist of the chase and the creator of “Mr. Jorrocks,” the fox-hunting London grocer, was born at The Ridings, Northumberland, on May 17, 1805, of an ancient Durham family. He was educated

at Durham grammar school, articled to solicitors in Newcastle and London, and admitted in 1828 but never practised law. From the days when he followed his father's hounds, hunting was his passion, but he had a taste for scribbling and took his writing seriously. A contributor to the *Sporting Magazine*, he broke away and, with Rudolph Ackermann as publisher, launched the *New Sporting Magazine* (N.S.M.) in 1831, editing it till 1836. He stood for Parliament unsuccessfully as a Conservative in 1837, took over the family seat, Hamsterley Hall, on his father's death in 1838, and was appointed a magistrate, deputy lieutenant for the county of Durham (1842), and high sheriff (1856).

Surtees' novels appeared as serials in the N.S.M. or elsewhere, or in monthly parts before final publication in book form, and these first and last dates are given after their titles. *Jorrocks' Jaunts and Jollities* (1831, 1838), a collection of tales; *Handley Cross* (1843 in 3 vol., expanded 1854), Surtees' own favourite; and *Hillingdon Hall* (1843, 1845) all immortalize Mr. Jorrocks, one of the great comic characters of English literature, as blunt as John Bull and entirely given over to hunting. There followed *Hawbuck Grange* (1846, 1847), *Mr Sponge's Sporting Tour* (1849, 1853), *Ask Mamma* (1857, 1858), *Plain or Ringlets?* (1858, 1860), and *Mr Romford's Hounds* (posthumous, 1865). Connoisseurs generally put first the chronicles of Soapey Sponge and Facey Romford, two cool horsemen and near-blackguards, whose chief business it is to pass off dangerous horses as tractable animals. In nearly all these books Surtees was fortunate to have two such illustrators as John Leech and Hablot K. Browne (“Phiz”).

Surtees' style is plain, even slapdash, and his books have their *longueurs*—reiterated lectures on hunting and land management; imagination burns low, but the ear for dialogue is acute and the observation telling. In fact, Surtees is a surprisingly mordant satirist, and the snobbery, envy, malice, greed, avarice, and ignorance that consume so many of his characters are set down with no particular geniality; the picture he paints, mainly of provincial England just leaving the coaching for the railway era, is an unamiable one of boredom, ill manners, discomfort, and horribly coarse food, and its very matter-of-factness, with detail as clear as that of a sporting print, makes admirable social history. Yet the descriptions of fast runs with hounds over open country—perhaps the next best thing to a day in the open air—leave the most lasting impression.

The novelist Thackeray, Surtees, and John Leech, three close friends, died within ten months of each other, Surtees at Brighton on March 16, 1864.

**SURVEYING** is the science that deals with relatively large-scale, accurate, geometrical measurement. It includes the determination of the measurement data, the reduction and interpretation of the data to usable form, and, conversely, the establishment of relative position and size according to given measurement requirements. Thus surveying has two similar but opposite functions: (1) the determination of relative horizontal and vertical position, such as that used for the process of mapping; and (2) the establishment of marks to control construction or to indicate land boundaries.

When highly accurate surveying is used in connection with the construction of large products or the jigs and fixtures used to make them, it is called optical tooling or optical metrology.

Surveying has been an essential element in the development of man's environment for so many centuries that its importance is often forgotten. It is an imperative requirement in the planning and execution of nearly every form of construction. Surveying was essential in the great waterworks created at the dawn of history, and some of the most significant scientific discoveries could never have been implemented were it not for its far-reaching achievements. Its greatest fields are transportation, building, apportionment of land, and communications.

**History.**—It is very probable that surveying had its origin in ancient Egypt. In the tomb of one Menna at Thebes there is a

representation on the walls of two chainmen surveying a field of corn, and in Ptolemaic and Roman papyri in the same country, measurements of plots of land are described. That the early Egyptians could carry out measurements with a considerable degree of accuracy is certain from a study of the dimensions of the Great Pyramid.

In Roman times the groma, which consisted of two pairs of plumb lines suspended from the ends of two horizontal rods placed at right angles to each other, was used to lay out lines at right angles. An early groma of the same type, but rougher construction, has been found in Egypt. The Romans certainly made use of an instrument not unlike the plane table for determining the alignment of their roads. The Greeks used a form of log line for recording the distances run from point to point along the coast while making their slow voyage from the Indus to the Persian Gulf about 325 B.C. Still earlier (as early as 1600 B.C.) it is said that the Chinese knew the value of the lodestone and possessed some form of magnetic compass. The earliest maps were based on inaccurate astronomical determination, but not until medieval times, when the Arabs made use of the astrolabe, could nautical surveying really be said to begin. In 1450 the Arabs were aided by the compass in charting the coastlines of those countries that they visited. Plane tables were in use in Europe in the 16th century, and the principle of graphic triangulation and intersection was practised by surveyors in England and elsewhere. In 1615 Willebrord Snell, the Dutch mathematician, measured an arc of meridian by instrumental triangulation.

Modern developments in electronics, optics, photography, reproduction, and aviation greatly influenced modern surveying. During World War II, the U.S. Army Map Service and its affiliated organizations prepared more than 30,000 different maps and reproduced more than 500,000,000 individual map sheets.

**Fundamentals.**—In contrast to other types of metrology (*q.v.*), nearly all surveying measurements are made either perpendicular to the direction of gravity (designated as horizontal) or in the direction of gravity (designated as vertical). When not so made, the quantities are immediately reduced mathematically to their horizontal or vertical equivalents. Thus the direction of gravity must be determined whenever a surveying measurement is made. It follows that only four types of measurements are determined: (1) horizontal lengths or distances; (2) vertical lengths or differences in height or elevation; (3) horizontal angles measured in planes horizontal at the vertex; and (4) vertical angles measured in vertical planes.

Horizontal lengths, with few exceptions, are measured in short, straight sections, which together are practically equivalent to an arc everywhere perpendicular to gravity.

Vertical measurements use as a reference a level surface, which, in considering the earth, is a curved surface everywhere perpendicular to gravity, such as the surface of still water. The surveyor's level, when properly operated, is an instrument that establishes a line of sight that is very nearly perpendicular to gravity at the instrument and maintains this angle without change in whatever direction it is pointed. At equal distances from the instrument the line of sight marks the position of a certain level surface. Thus the difference in height between two points is the vertical distance between the level surfaces that pass through them (see *Orthometric Corrections*, below). To determine the difference in height, the level is placed equidistant between the two points, and the graduations are read on a rod held vertically on each in turn. For less accurate results, the equality of hori-

zontal distances need not be very accurately maintained. Variations in atmospheric refraction restrict the distances from the instrument to the points observed so that the difference in height between widely separated points is determined by a series of measurements over temporary points. This operation is called leveling, or running a line of levels.

Within any strip on the earth's surface about 12 mi. (20 km.) wide, and without large differences in altitude, the differences are negligible between the horizontal or vertical measurements made as described above and the same measurements reproduced on, or from, a plane surface where the directions of gravity would be parallel. Thus the results of such surveys are computed by plane trigonometry, and the whole process is called plane surveying.

For surveys outside these limits, geodetic computation must be used if geometric inconsistencies are to be avoided; this process is called geodetic surveying. Since geodetic surveys must be very accurate, the instruments used must be unusually precise, and they are often called geodetic instruments, even though they may be used for other types of accurate surveys.

**Units of Measure Used in Surveying.**—The metre is the fundamental unit of length used throughout the world. In 1889 the length of the metre was defined in terms of the International Prototype Metre, a platinum-iridium bar kept at the International Bureau of Weights and Measures at Sèvres, France. In October 1960, the length of the metre was redefined as equal to 1,650,763.73 times the wavelength of krypton-86 under specified conditions. This stabilized but did not effectively change the length of the metre.

From 1893 until 1959, the foot used in the United States equalled  $\frac{1}{3.28084}$  m., or 0.30480061 m. It was not quite the same length as the foot used in other English-speaking nations, as these were based on the imperial yard, whose relationship with the metre apparently varied slightly from time to time.

In 1959 it was agreed by representatives of the English-speaking nations to base the foot on the metre according to the exact ratio: 1 ft. = 0.3048 m. This shortened the foot used in the United States by about 2 parts in 1,000,000 and lengthened the contemporary British foot by about  $\frac{1}{4}$  part in 1,000,000.

The U.S. Coast and Geodetic Survey, which maintains the fundamental survey control systems in the United States, measures in metres. Since 1893, this survey has converted to values in feet by the ratio  $\frac{1.2500}{3.28084}$  in all publications in which the foot appears. It was necessary, in order to avoid confusion, to retain this value of the foot until such time as all vertical and horizontal control systems should be readjusted. Accordingly, this foot was named the U.S. Survey Foot.

Today, except in rare instances, the only unit of length used in surveying, in addition to metric units, is the foot (e.g., 1 station = 100 ft., and decimals of tenths, hundredths, and thousandths of a foot are used instead of inches and fractions). In optical tooling the inch and decimals of an inch are used exclusively (e.g., 20 ft. would be termed 240 in.).

Two types of angular measure are used throughout the world as follows:

Sexagesimal System	Centesimal System
1 circle = 360 degrees (°)	1 circle = 400 grads (g)
1 degree = 60 min. (')	1 grad = 100 min. (')
1 min. = 60 sec. (")	1 min. = 100 sec. (")

Directions are given in azimuths or bearings. Azimuths are clockwise angles from the north, or occasionally from the south. Equivalent values are the following:

Azimuth from North	50°	120°	200°	310°
Azimuth from South	230°	300°	20°	130°
Bearing	N 50°E	S 60°E	S 20°W	N 50°W

**Surveying Instruments.**—There are four fundamental surveying instruments: the steel tape, the theodolite (or transit), the compass, and the level. Each requires supplementary equipment, and each has a number of forms for special purposes.

**The Steel Tape**, which consists of a graduated steel ribbon, is

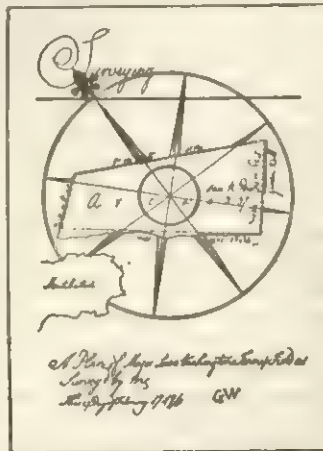

FIG. 1.—A PLAN MADE BY GEORGE WASHINGTON IN 1746, INSCRIBED IN HIS OWN HANDWRITING

a flat wire, with handles at each end, is the basic means of measuring distance. Its length is taken as the straight-line distance between the two end marks at  $68^{\circ}\text{ F}$  ( $20^{\circ}\text{ C}$ ). Thus its length is different with different types of support and under different tensions. When compared to a standard to determine its length, tensions and types of support are used which are likely to be used in the field. In the field, if accuracy is desired, the type of support, the tension, the temperature, and the difference in height of the two end marks must be recorded and the measured length corrected accordingly.

In most routine surveys, the tape is held by hand at the ends, kept high enough to clear ground objects, made horizontal by estimation, and placed in the direction of measurement by eye or with an instrument. The desired tension is estimated, and the positions of the graduations are brought to the ground marks by plumb bobs. Sometimes the air temperatures are recorded. For higher accuracy, tripods or other more definite types of support are employed, or the tape is fully supported on smooth surfaces. The slopes of the tape are measured directly or determined by leveling, and tape temperatures are ascertained by thermometers with their bulbs in contact with the tape. The tension is regulated with a spring balance, and the tape is in actual contact with the surfaces where the marks are placed.

Accurate electronic distance-measuring devices are often used to measure long traverse courses, long triangulation base lines, and for trilateration, which is the measurement of the sides of a system of triangles. When supported in an airplane, these electronic devices are used to measure distances over water where the earth's curvature prevents triangulation.

The *Theodolite (Transit)* is used to measure horizontal and vertical angles. It often has a compass for determining magnetic bearings and a spirit level containing a bubble in a liquid attached to the telescope for establishing a horizontal plane and for running levels. The telescope objective lens forms an image on the plane of the reticle, where a pattern, etched on glass, or cross hairs mark a point. An eye-piece (ocular) magnifies both the image and the cross hairs so that the observer sees the cross hairs on the object sighted, at the point of aim (on the line of sight), while the view is magnified about 20 to 30 diameters.

The telescope turns vertically through  $360^{\circ}$  on a horizontal (elevation) axis established by bearings in two uprights (standards). A graduated vertical circle turns with the telescope past an index on a standard and thus measures vertical angles.

The standards are mounted on a horizontal plate which carries one spirit level, or two at right angles, and usually two indices  $180^{\circ}$  apart for reading a horizontal graduated circle. The average of the two readings is free from the effects of eccentricity in the circle graduations. The plate is mounted on a vertical spindle that allows it to turn in a horizontal plane about a vertical axis (azimuth axis), and the horizontal axis is adjusted so that it is perpendicular to the vertical axis. The parts so far described are called collectively the alidade.

In nearly all European instruments and in special U.S. instruments the spindle turns in a bearing in the base, or leveling head, and the graduated horizontal circle for measuring horizontal angles turns in a separate bearing also in the leveling head. The rotation of the alidade with respect to the leveling head is controlled by a clamp and a tangent screw that permits slow motion. The circle is held in directional position by friction, but it can be turned by hand to approximate settings so that various parts of the circle can be used to measure an angle; thus the effects of circle-graduation inaccuracies can be reduced by averaging. This instrument is called a directional theodolite, or merely a theodolite.

The American instrument has a unique feature known as the double centre, on which the circle is mounted. It can be visualized as a thick, vertical, conical tube. The inner surface provides the bearing for the alidade spindle, and the outer surface turns in a bearing in the leveling head. An upper clamp and tangent screw (the "upper motion") control the rotation between the alidade and the circle, while a similar "lower motion" controls the rotation between the circle and the leveling head. With this arrangement, the alidade index can be set at zero on the circle by operating the upper motion. By using the lower motion, the line of sight can then be turned to the target that marks the first side of the angle without disturbing the zero setting. When the telescope is turned to the second side of the angle, by means of the upper motion, the alidade index will read the value of the angle. Furthermore, by returning the aim to the first target with the lower motion and repeating the process, a second value of the angle is added, and this can be continued indefinitely. When the final angle reading is divided by the number of times the angle is turned off, a very accurate value of the angle is obtained. This instrument is known as a repeating transit, or merely a transit.

The base of the leveling head of a theodolite or a transit is screwed on a tripod or some other support. The bearings for the alidade can be tilted slightly by either three or four leveling screws, thus placing the vertical axis in the direction of gravity according to the spirit level or levels on the plate.

Three-screw leveling heads are much easier and faster to use, but they sometimes allow the circle to rotate a little. Four-screw types, though safer, are more difficult to use, and they tend to deform the vertical bearing slightly.

A plumb bob or a vertical sighting device is used to place the instrument centre over the point of observation. The instrument can be shifted laterally for final positioning.

Originally all horizontal-angle measuring instruments were called theodolites. The poorer optics of earlier times required a very long telescope. To eliminate the effect of residual errors in the adjustment of the horizontal axis, or to prolong a line, the telescope had to be reversed in direction by lifting it out of its bearings and turning it around. With improvement in optics, the telescope was made short enough to be reversed by turning it in its bearings vertically through the zenith, that is, causing it to transit (hence the name "transit theodolites"). Today the name "transit" is usually reserved for repeating instruments.

Directional instruments (theodolites) can give results very rapidly in triangulation. For this purpose highly precise circle-reading devices are required. Modern instruments contain glass circles and micrometers with glass scales, both of which are illuminated from below.

FIG. 2.—THEODOLITE

BY COURTESY OF ENGIS EQUIPMENT COMPANY

Repeating instruments (transits) are equipped with vernier indices (scales). Single angles can be measured to the same accuracy and in about the same time as with theodolites. However, they are somewhat difficult to read. On the other hand, transits are much better than theodolites for staking purposes.

In an effort to compete with the American transit, European theodolite manufacturers have introduced a snap clamp that locks the circle to the alidade. This makes it possible to start at zero when measuring an angle and to repeat angles. Unfortunately, operating the clamp changes the setting slightly, and, since both the circle bearing and the alidade bearing are used simultaneously, the eccentricity between them introduces small errors that do not occur in transit operation.

Compasses of two needle-types are used: box compasses and circular compasses. Box compasses must be used with angle-measuring instruments, as they operate only when the line of sight points toward magnetic north. The bearing desired must then be measured from this direction.

Circular compasses can be mounted on theodolites and are often permanently mounted on transits. When provided with open sights, they can be used alone either mounted on light tripods or held in the hand.

**Surveying Levels** are of three types: (1) the wye or the dumpy level; (2) the tilting level; and (3) the self-leveling level. The first type consists of a telescopic sight, like that of a transit but usually of slightly higher magnification, to which a long spirit level is attached and adjusted so that the bubble centres when the line of sight is horizontal. The whole is mounted on a spindle in a leveling head so that it can be turned in direction. The telescope of the wye level can be rotated and changed end for end in the wyes for adjustment.

The tilting level is similar but the telescope can be tilted with respect to the spindle by means of a micrometer screw. The spindle is set nearly vertical with a circular spirit level, and the main bubble is centred with the micrometer screw.

The self-leveling level is similar to the tilting level, except that it has no micrometer screw. Instead, it contains an optical part that is operated by a pendulum in such a way that the line of sight is made horizontal automatically. Some types are extremely accurate, and all eliminate the time-consuming operation of centring the main bubble.

For very accurate work, tilting levels are equipped with coincidence-reading bubbles. By an optical device the bubble is split in half longitudinally, and the ends are shown with their centre-lines adjacent. When the two ends are made to coincide, the bubble is precisely centred. Often tilting and self-leveling levels have three horizontal cross hairs so that three readings of the staff (rod) can be taken and averaged. Also used are optical micrometers, which consist of thick glass disks with parallel optically flat surfaces usually mounted in front of the telescope. When these micrometers are rotated on a horizontal axis, they move the line of sight up or down and parallel to itself. A graduated drum indicates the distance moved from their normal position so that when the line of sight is placed exactly on a rod graduation, they read the very small additional quantity to be applied.

**Survey Control.**—The accuracy of survey measurements can be increased almost indefinitely, but only at increased cost. Accordingly, control surveys are used; these consist of a comparatively few, accurate measurements that cover the area of the project and from which short, less accurate measurements are made to the objects to be located. The simplest form of horizontal control is the traverse, which consists of a series of marked stations connected by measured courses and the measured angles between them. When such a series of distances and angles returns to its point of beginning, or begins and ends at stations of superior (more accurate) control, it can be checked and the small errors of measurement adjusted for mathematical consistency. By assuming or measuring a direction of one of the courses and rectangular coordinates of one of the stations, the rectangular coordinates of all the stations can be computed.

**Superior Horizontal Control** usually consists of a system of triangles. All of the angles and at least one side, called the base,

FIG. 3.—SYSTEMS OF TRIANGULATION

are measured. Though several arrangements of triangles are used, one of the best is the quadrangle, or a chain of quadrangles. In each quadrangle, the four sides and the two diagonals are used so that eight angles are measured. To be geometrically consistent, the angles must satisfy three so-called angle equations and one side equation. The slight departures from these requirements are adjusted, usually by the theory of least squares, so

that the results are very close to the true values. Rectangular coordinates are usually established as for traverses.

Since a number of sight lines extend from each triangulation station, it is difficult to find positions where triangulation stations can be located without the use of special towers. However, traverse stations can usually be successfully placed at ground level. This consideration often dictates which type of control is selected.

When the survey is so large that geodetic computation is necessary, a mathematical figure of the earth must be chosen as a reference surface. A level surface at mean sea level is considered to represent the earth's size and shape, and this is called the geoid (see also GEODESY). Due to gravity anomalies, the geoid is irregular; however, it is very nearly the surface generated by an ellipse rotating on its minor axis, i.e., an oblate ellipsoid of revolution. The exact size and shape of such a figure are completely defined by the lengths of its two axes. An ellipsoid that nearly represents the geoid can be deduced from the results of triangulation systems which extend a considerable distance north and south and from astronomical observations connected with them. Such a figure is called a spheroid. Several have been computed by various authorities, but that usually used as a reference surface by English-speaking nations is known as Clarke's spheroid of 1866.

All length measurements are reduced to their sea-level equivalents, i.e., to the geoid. These are assumed to be the distances, measured on the spheroid, between the normals to the spheroid that would pass through the ends of the measured lengths. Spherical excess is taken into account in angular computations. The positions of the stations are given in spherical coordinates (i.e., geodetic latitude and longitude) which are computed as though the directions and distances were measured on the spheroid. It should be noted that, while astronomical observations are used to establish the position and orientation of a triangulation system, at most stations astronomical determinations will differ slightly from geodetic values, as astronomical observations are referred to the local direction of gravity. The difference between the normal to the spheroid and the direction of gravity is often called the deflection of the plumb bob.

As geodetic computation is somewhat cumbersome, some nations have established a series of strips (zones) within which plane computations can be made. The plane rectangular coordinates for the triangulation stations within each zone have been computed, usually on some form of the Lambert coniform projection or the transverse Mercator projection, which is also conformal (see MAP: Map Projections). In the United States these are called the state plane coordinate systems. These are usually 125 mi. wide and are arranged so that the maximum differences between lengths on the spheroid and those computed by the coordinates are 1 part in 10,000.

**Vertical Control** consists of marked points, called bench marks, connected by precise leveling. The elevations of these points are given in terms of their heights above a selected level surface called a datum. In large level surveys the level surface usually selected is the geoid. The elevation taken as zero is the height of mean sea level determined by a series of observations at various points along the seashore taken continuously for a period of 19 years or more.

**Orthometric Corrections** must be applied to long lines of levels at high altitudes that have a north-south trend. Since the level surfaces, determined by leveling, converge slightly toward the earth's poles due to the reduction in centrifugal force and the increase in the force of gravity at higher latitudes, the distances between the surfaces and the geoid do not exactly represent their height above the geoid.

Trigonometric leveling is often used where accurate elevations are not available or when the elevations of inaccessible points must be determined. From two points of known position and elevation, the horizontal position of the unknown point is found by triangulation, and the vertical angles from the known points are measured. The differences in elevation from each of the known points to the unknown point can then be computed trigonometrically.

When large areas must be mapped where accurate control is lacking, positions are determined astronomically, and elevations are measured by barometric pressure, usually determined by sensitive aneroid barometers (altimeters) or by hypsometers, which determine the temperatures of boiling water. Readings must be compared to those of a base instrument at a known elevation and corrected for air density estimated from the barometric pressure and the values of temperature and humidity. When two or more bases are used at well-separated elevations, proportional interpolation of results automatically eliminates the need for air-density corrections.

Finally, elevations are measured from aircraft by determining the height above the ground with electronic devices and the elevation of the aircraft by altimeter or trigonometric leveling.

**Maps and Charts.**—A complete map or chart shows the horizontal size, position, and elevation of natural and man-made topographic features according to a scale or, if the earth's curvature is considered, according to a mathematical projection. The shape of the ground in elevation is shown by contour lines that connect points of equal elevation; water depths are shown by spot depths and sometimes by lines of equal depth. Small-scale maps and charts show lines of latitude and longitude; large-scale maps show an indication of geodetic, astronomic, or magnetic north and often the lines of a rectangular coordinate system. Maps or charts made for special purposes omit many of these features.

A profile is a line which shows to scale, by its height, the elevation of the ground or other features along a selected route. Frequently the profiles of several features are shown on the same drawing.

Due to the immense importance of maps and charts, large areas of the earth have been surveyed, mapped, and charted, with the results published by government agencies. Government triangulation systems cover most of the world and are connected over oceans by wireless time, observations of moon occultations, ordinary astronomical observations, and satellite triangulation. Smaller bodies of water, where the earth's curvature prevents ground triangulation, are crossed by trilateration measured with electronic devices or triangulation by simultaneous observations to flares dropped from an airplane. Level nets (interconnecting networks of level circuits) based on mean sea level give elevation control. Secondary triangulation and levels are established where the mapping will be carried out. Photogrammetry (*q.v.*) is used almost exclusively for supplying detail. The photographs are usually connected to the control by transit-stadia and plane-table measurements to ground objects shown on the photographs.

Stadia is a method of measuring distance, direction, and difference in height by observing a graduated rod with a transit telescope or the telescope of a plane-table alidade. The telescope has two supplementary horizontal cross hairs in the reticle, equally spaced above and below the central horizontal cross hair. They are spaced so that they intercept on the rod, usually  $\frac{1}{100}$  of the distance from a point at the instrument to the rod. This intercept, the direction, and the vertical angle are read and then reduced to the desired values by slide rule or tables.

The plane table consists essentially of a drawing board mounted on a tripod. The alidade is a telescope with a vertical-angle circle that is mounted on standards attached to a straightedge. Once

aimed, the stadia intercept and the vertical angle are read, and the direction is recorded by drawing a line along the straightedge. Thus points are located and a map can be drawn as the work progresses.

Surveys for smaller maps are usually based on traverse and sometimes triangulation with a rudimentary level net to control elevations. Detail is filled in by transit-stadia on the plane table. Where elevations are important, the area is laid out in squares and the elevations of the intersections are determined with a level.

**Route Surveys.**—Route surveys are required for all forms of transportation, but those for canals, railways, and highways require the greatest accuracy. A strip map is made of the most probable route, which is controlled by a traverse and a single line of levels, and photogrammetry is usually used for details. For small surveys, profiles are measured at right angles to the traverse, and contour lines are drawn connecting them. Other details are located by right-angle distances (offsets) from the traverse and the distance along the traverse to the foot of the perpendicular.

The centreline of construction, composed of straight lines (tangents) and circular curves, is laid out on the map and then marked on the ground where the required limits of rate-of-grade and curvature can be met with the greatest economy. Changes in rate-of-grade are connected by vertical curves, which are parabolas with vertical axes. Occasionally, in the final layout, spirals are used to connect curves with tangents or other curves.

Detailed construction is usually laid out by measurements from the centreline and the original line of levels. Often the centreline is represented by a base line parallel to it.

The computation of earthwork volumes and the complicated computations required for highway interchanges are nearly always handled by electronic computers.

**Nautical Charts.**—Horizontal control for a chart usually consists of triangulation established on land and on stationary positions in the water, such as lighthouses. Traverse is frequently used on land, and usually special land targets are built to mark ranges from which the positions of soundings can be determined. These targets, the shore line, and other objects used for navigation or construction are located from the control.

Water depths, which are recorded in feet or fathoms (units of six feet), are measured by soundings with poles, weighted lines, or Fathometers, which time the interval between the emission of a sound near the water surface and the return of the echo from the bottom. Isolated rocks, wrecks, or other obstructions are found by a wire drag, which is held level by buoys at the desired depth and towed over the area.

In tidal waters, one or more automatic tide gauges are established to make a continuous record of the height of the water against time. The time of each sounding is recorded so that the depths measured can be reduced to a selected datum, usually mean low water or lower low water. The datum is established by a comparison of the tide gauge records and those of the nearest permanent tidal station.

The horizontal positions of soundings are determined by triangulation from shore, timing on ranges, stadia, wire-line measurements, timing sound impulses through the water, electronic measuring devices, and by the simultaneous measurement from the sounding craft of the two angles between three targets on shore. A sextant (*q.v.*) held on its side is used to measure these angles.

**Property Boundary Surveys.**—These surveys constitute a large, highly specialized branch of surveying known as land surveying. Not only must a land surveyor be thoroughly versed in surveying techniques, but he must thoroughly understand real property law, be very familiar with property lines within the area of his work, and be able to make decisions that he can justify in court when appearing as an expert witness.

In general, property boundary lines must be shown by marks on the ground (landmarks), often called monuments. These usually consist of ridges, streams, blazed lines, ditches, walls, fences, trees, field stones, stakes, iron pipes or rods, or prepared square concrete or stone posts sunk vertically into the ground.

Land surveying as we know it was first used to determine acre-

age. The directions of the boundary lines were determined by compass, and their lengths were determined usually by an actual chain made of wire links. These lengths and bearings were used to compute the acreage and were included in land descriptions to aid in identifying monuments. The chain used in most English-speaking nations is Gunter's chain, 66 ft. long and made of 100 links. Ten square chains equal one acre. Other units associated with the chain are the rod, pole, or perch, each 25 links long, and a square chain contains 4 roods. One rood equals 40 perches or square rods. The United States and Canadian public land systems are based on the chain, and many land descriptions there and elsewhere contain this unit.

With the introduction of the transit and tape, it became possible to locate land boundaries accurately by measurement from any monumented line so that the recorded measurements gained in importance and fewer monuments were used.

Since the cost of a survey increases with its accuracy, surveys of low-priced land are seldom very accurate. When placed together, they overlap or gap, often containing errors or omissions, and frequently the same line in abutting parcels is recorded with different directions and lengths in the two descriptions. Moreover, monuments disappear and natural monuments, such as trees or field stones, are often destroyed or cannot be identified. In localities where land is increasing in value, an almost universal condition, these inconsistencies must be eliminated. While the power of decision rests with the court, the land surveyor must reach a solution based on his experience, his estimate of the accuracy of the work of the previous surveyors, his familiarity with the property lines in the vicinity, and his knowledge of the law.

**SURVILLE, CLOTILDE DE**, supposedly a 15th-century French poet and author of the so-called *Poésies de Clotilde*. Legend has it that the poet's full name was Marguerite Éléonore Clotilde de Vallon-Chalis, born in 1405 in the chateau of Vallon and married in 1421 to Bérenger de Surville, who was killed at the siege of Orléans in 1428. Her poems are said to have been inspired by her husband's absence and death in the war. Research has shown, however, that Bérenger married a widow, Marguerite Chalis from Privas, on Jan. 4, 1428, and that he was still alive in 1448.

The *Poésies de Clotilde*, about 50 poems treating of love and war, were first published partly by Charles Vanderbourg (1803) and partly by De Roujoux and Charles Nodier (1827) from alleged copies of manuscripts made by a descendant of Clotilde, the marquis Joseph-Étienne de Surville (1755–98). They were quickly recognized as spurious; both in form and allusion (e.g., to Coper-

FIG. 4.—BENCH MARK TABLET USED IN THE UNITED STATES

nicus) they are out of keeping with their supposed period. They were almost certainly written by the marquis himself, a man with literary ambitions, who published similar poems of his own.

See A. Mazon, *Marguerite Chalis et la légende de Clotilde de Surville* (1873); W. Koenig, *Étude sur l'authenticité des poésies de Clotilde de Surville, poète français du XV<sup>e</sup> siècle* (1875). (F. J. We.)

**SUSA** (SHUSHAN, SHUSH), capital of Susiana (Elam, q.v.) and chief residence of Darius I and his successors from 521 B.C. It lay at the foot of the Zagros Mountains at about latitude 32° N, near the bank of the Karkheh (Choaspes) River, and close to the Karun River in what is now Iran (see IRAN: Archaeology).

The site, identified (1850) by W. K. Loftus, has on it four mounds. One, rising about 38 m., holds the citadel. A second to the east represents the palace of Darius I and was excavated by M. Dieulafoy. The enameled bricks taken from its walls are in the Louvre, Paris. A third mound to the south contains the royal Elamite city, while the fourth mound consists of the poorer houses. Excavation of the citadel was begun by J. de Morgan in 1897. It yielded the obelisk of Manistusu, the stele of King Naramsin, and the code of Hammurabi (the latter in the winter of 1901–02).

The finest pottery came in the lowest strata, 25 m. below the surface and belongs to two different civilizations, both Neolithic. The earlier is characterized by vases of fine red clay, wheel made, in a few well-defined shapes, and all with thin, polished sides. The decorations applied in black paint or red-brown ferruginous (iron-bearing) earth consist of bold geometrical patterns, often combined with spirited studies from nature. The pottery of the second period shows a retrogression, being coarser and porous.

Above the early strata come remains of Elamite and early Babylonian civilizations, inscribed objects from the latter bearing pictorial characters from which the cuneiform (q.v.) was evolved. The upper portions of the mounds disclosed inscribed Achaemenian monuments, Greek pottery and inscriptions of the 4th century B.C., coins of the kings of Elam, and Parthian and Sasanian relics. Muslim tradition says that the tomb of the prophet Daniel lay in the bed of the Karkheh River, and a mosque was built on the bank opposite the supposed spot. Until after the 14th century the city was a flourishing centre of a district famous for silk, sugarcane, and oranges.

**SUSAH** (French SOUSSE), a town and port of eastern Tunisia and seat of a governorate, is the centre of the Sahel (As Sahil) region. Pop. (1963 est.) 52,000. The old town (*medina*), enclosed in ramparts that date from the Byzantine period and from the Aghlabid dynasty (9th century), and dominated by a kasbah, is on the side of a hill that leads down to the port. It encloses the Great Mosque and the Ribat (religious house), which date from the 9th century, the *sugs* (market places), and some Muslim quarters. Newer quarters have advanced for a long way to the north (on either side of the railway station), to the northwest, and to the south (the industrial quarter). The west is occupied by the army camp. The town is linked by rail and road to Tunis, Sfax (Safaqis), Gabès (Qabis), and Gafsa (Gafsa), and by roads to the hinterland.

Two-fifths of the inhabitants of Susah are engaged in industry, which includes flour mills, olive oil and residuum plants, food preservation factories, mechanical workshops, a motor vehicle assembly plant, and cotton spinneries. Plastics are also manufactured. But its trade is limited by the competition from Mahdia (Al Mahdiah), in the south of the Sahel; and by the growing attraction of Tunis and Sfax. Exports from the port of Susah are

chiefly oils, followed by esparto grass, salt, and preserved fish. Imports, in unequal competition with goods arriving from Tunis by road and railway, are restricted to cotton thread and cloths, machinery, grain and sugar, some petroleum products, and building materials. The port also has a small fishing fleet.

Susah is the successor of the Phoenician (or Carthaginian) *Hadrumentum* (q.v.). It declined under the Arab conquest but was revived by the Aghlabid rulers of Kairouan (Al Qayrawan), whose port it became and remained until the invasions of the Bedouin Arabs in the 11th century (see *TUNISIA: History*). These incursions ruined Kairouan and Tunisia and greatly restricted the activity of Susah. Its revival, after two centuries of decline, was thereafter associated with that of the Sahel. Susah is actually the centre for a region of over 600,000 inhabitants, which, with its lightly undulating landscape and nucleated villages, has an old tradition of olive cultivation. It was gradually reestablished from the 13th century and developed greatly under the French protectorate (1881–1955); it had 50 villages and 9,000,000 olive trees. Its surplus population, however, has been emigrating to Tunis.

See J. Despois, *La Tunisie orientale: Sahel et Basse Steppe*, 2nd ed. (1955). (J.-J. Ds.)

**SUSANNA** (SUSANNAH), an Old Testament writing not included in the Hebrew Bible, hence counted apocryphal by Protestantism. The story comprises ch. 13 of the Book of Daniel in the Vulgate (Latin) Bible and in English Bibles descended from it. See *APOCRYPHA, OLD TESTAMENT* (for status of the Standard Apocrypha); *DANIEL, BOOK OF*.

**SU SHIH**: see *SU TUNG-P'Ö*.

**SUSO** (SEUSE), **HEINRICH** (c. 1296–1366), Swabian mystic, the most renowned pupil of Meister Eckhart (q.v.) and read and admired by Thomas à Kempis, was born at Überlingen, on the German shore of Lake Constance, or possibly at Constance itself. At the age of 14 he joined the Dominican Order in Constance, where, five years later, he underwent a religious experience that gave a lasting and distinctive character to his spiritual life, all of which is marked by his self-dedication, made at that time, to the Eternal Wisdom. (Testimony of the so-called *Life of the Servant* concerning the early decades of his religious life is open to serious reserves.) Sometime before 1327 he went to Cologne for further theological studies and, together with Johann Tauler, was a pupil of Meister Eckhart. His first work, the *Little Book of Truth* (c. 1329), was occasioned by the controversies stirred up by the trial of his teacher. About ten years later he composed in Latin the *Horologe of Wisdom*, the most durably popular and influential of his writings. The *Little Book of Eternal Wisdom* (of which, at one time, the *Horologe* was thought to be a free translation) seems to come from the period of his maturity, about 1348. The most attractive of the Rhineland mystics and the easiest to comprehend, Suso presents a doctrine, Neoplatonic and Thomist, which in orientation is Eckhartian but in content quite as own.

He died at Ulm on Jan. 25, 1366. He was beatified in 1831, and his feast is celebrated on March 2.

The most reliable text of the German writings is that established by K. Bihlmeyer, *Heinrich Seuse: Deutsche Schriften* (1907); of the *Horologe* it is *Colloquia Dominicana . . . a Beato Henrico Susone dictata* (1923). The best English translations are those of J. M. Clark: *The Life of the Servant* (1952) and *Little Book of Eternal Wisdom* and *Little Book of Truth* (1953).

See C. Gröber, *Der Mystiker Heinrich Seuse* (1941); J. A. Bizet, *Henri Suso et le déclin de la scholastique* (1946); J. M. Clark, *The Great German Mystics*, pp. 54–74, with bibliography, pp. 114–117 (E. O'B.)

**SUSQUEHANNA**, the longest river in the eastern United States, rises in Otsego Lake, central New York, and flows southward into Chenango County, N.Y., where it heads southward into Susquehanna County of northeastern Pennsylvania. The river then changes its direction northward and enters south-central New York for a short distance before again turning southward into Bradford County, Pa. After flowing southeastward through the Allegheny Plateau it enters the Ridge and Valley Province north of Wilkes-Barre and changes its course southwestward,

following one of the major longitudinal valleys. At Sunbury this part of the river, called the North Fork, is joined by the West Branch. The stream then turns southeastward, crossing five ridges and forming water gaps, after which it traverses the Piedmont plateau and empties into Chesapeake Bay at Havre de Grace, Md.

Prior to the Pleistocene ice age the Susquehanna drained most of central New York state, but due to morainal deposits across the state the northern tributaries were blocked. At the mouth of the Susquehanna a submarine channel extending eastward across the Continental Shelf indicates the presence of the former valley of the river.

The West Branch of the Susquehanna, 160 mi. in length, rises in the Allegheny Plateau of Indiana County, west-central Pennsylvania. The river flows northeastward to Williamsport and then turns southward to Sunbury. The North Fork falls 1,923 ft. and the West Branch falls 688 ft. The major tributaries are the Chemung and Juniata rivers.

Important cities on the Susquehanna river are Binghamton, N.Y., and Wilkes-Barre, Berwick, Sunbury, and Harrisburg, Pa. Williamsport is the major city of the West Branch. Due to rock obstructions and rapids the Susquehanna is not navigable; an abandoned canal at its mouth once made the river navigable for a short distance. The Susquehanna presents the greatest water-power potential of rivers in the eastern United States. There are hydroelectric power plants at Holtwood and Safe Harbor, Pa., and Conowingo, Md. (E. W. Mr.)

**SUSSEX, EARLS AND DUKE OF**. The English title of earl of Sussex has been held by several families since its creation in the 12th century. The dukedom was created in 1801. The early history of the earldom is involved in some obscurity, for in the 12th and 13th centuries the same person is sometimes described as earl of Sussex, sometimes as earl of Chichester (the chief town of the county), and sometimes as earl of Arundel (the principal seat). Roger de Montgomery (d. 1094), who was created an earl in 1067 and received a large part of Sussex from William the Conqueror, was the first to be known as earl of Sussex, but the title of earl of Sussex was formally created by King Stephen in 1141 for WILLIAM D'AUBIGNY (d. 1176). He was the husband of Adelaide, widow of Henry I, who had received the Sussex estates after 1102 when Montgomery's son Robert, 3rd earl of Arundel, was attainted and the estates were forfeited to the crown. William and his descendants were usually styled earls of Arundel (see *ARUNDEL, EARLS OF*). William's grandson WILLIAM (d. 1221), 3rd earl, was a favourite of King John and was one of his sureties for the observance of Magna Carta. On the death without issue of his second son, HUGH (d. 1243), 5th earl, the earldom reverted to the crown. John de Warenne (1231–1304), 7th earl of Surrey, the brother of Hugh's wife Maud, and John's grandson John (1286–1347), 8th earl of Surrey, were sometimes styled earls of Sussex, but neither possessed the earldom. (See *WARENNE*.)

**Radclyffe Earls**.—There was no earl of Sussex from 1243 until 1529 when the title was conferred on ROBERT RADCLYFFE (Ratcliffe; c. 1483–1542). Created Viscount Fitzwalter in 1525, he became great chamberlain of England in 1540. His grandson THOMAS (c. 1525–83), 3rd earl of his line, was lord lieutenant of Ireland (see *SUSSEX, THOMAS RADCLIFFE, 3RD EARL OF*). Thomas' brother HENRY (c. 1532–93), 4th earl, served in Ireland from 1556 until about 1565. ROBERT (1573–1629), 5th earl, Henry's only son, died without legitimate living issue, and on the death of EDWARD (1559–1643), 6th earl, the son of Humphrey, third son of the 1st earl, the title became extinct.

**Savile, Lennard, and Yelverton Earls**.—THOMAS SAVILE (1590–c. 1659), son of John (1566–1630), 1st Baron Savile of Pontefract, was created earl of Sussex in 1644. His fluctuating allegiance in the English Civil War led to his imprisonment for a short time by both Charles I and by Parliament. The title became extinct on the death of his son JAMES (1647–71), 2nd earl of his line. It was revived in 1674 for THOMAS LENNARD (1654–1715), 15th Baron Dacre, soon after his marriage to Anne, the daughter of the duchess of Cleveland probably by Charles II. The title became extinct on the death of Thomas and was conferred in

1717 on TALBOT YELVERTON (1690–1731), 2nd viscount de Longueville, from whom it descended to his sons GEORGE (1727–58), 2nd earl of his line, and HENRY (1728–99), 3rd earl, on whose death it became extinct.

**Dukedom and Royal Earls.**—AUGUSTUS FREDERICK (1773–1843), the sixth son of George III, was created earl of Inverness and duke of Sussex in 1801. A supporter of the Liberals, he gave active help to the movements for the abolition of the slave trade, Catholic emancipation, and parliamentary reform. He was president (1816–43) of the (Royal) Society of Arts and (1830–39) of the Royal Society. The dukedom became extinct on his death in 1843.

The earldom was revived in 1874 for ARTHUR WILLIAM PATRICK ALBERT (1850–1942), third son of Queen Victoria, who at the same time was created duke of Connaught and Strathearn (*see* CONNAUGHT, ARTHUR WILLIAM PATRICK ALBERT, DUKE OF). He was succeeded by his grandson ALASTAIR ARTHUR (1914–43), who died unmarried, when the titles became extinct.

**SUSSEX, THOMAS RADCLIFFE** or RATCLIFFE, 3RD EARL OF (c. 1525–1583), was lord lieutenant of Ireland and lord lieutenant of the north under Queen Elizabeth I. The eldest son of Henry, 2nd earl of Sussex, he was born about 1525, and after his father's succession to the earldom in 1542 was styled Viscount Fitzwalter. After serving in the army abroad, he was employed in 1551 in negotiating a marriage between Edward VI and a daughter of Henry II, king of France. His prominence in the kingdom was shown by his inclusion among the signatories to the letters patent of June 16, 1553, settling the crown on Lady Jane Grey; but he nevertheless won favour with Queen Mary, who employed him in arranging her marriage with Philip of Spain, and who raised him to the peerage as Baron Fitzwalter in Aug. 1553.

BY COURTESY OF BARON FITZWALTER

THOMAS RADCLIFFE, 3RD EARL OF SUSSEX, ABOUT 1565 BY AN UNKNOWN ARTIST

In April 1556, Fitzwalter was appointed lord deputy of Ireland. The measures enjoined upon Fitzwalter by the government in London comprised the reversal of the partial attempts that had been made during the short reign of Edward VI to promote Protestantism in Ireland, and the "plantation" by English settlers of that part of the country then known as Offaly and Leix. But Fitzwalter first of all found it necessary to make an expedition into Ulster. Having defeated Shane O'Neill and his allies the MacDonnells, the lord deputy, who by the death of his father in Feb. 1557 became earl of Sussex, returned to Dublin, where he summoned a parliament in June of that year. Sussex then took the field against Donough O'Connor, whom he failed to capture, and afterward against O'Neill, whose lands in Tyrone he ravaged, restoring to their nominal rights the earl of Tyrone and his reputed son Matthew O'Neill, baron of Dungannon. (*See* O'NEILL.) In June of the following year Sussex turned his attention to the west, where the head of the O'Briens had ousted his nephew Conor O'Brien, earl of Thomond, from his possessions, and refused to pay allegiance to the crown; he forced Limerick to open its gates to him, restored Thomond, and proclaimed Donnell O'Brien a traitor. He took part in the coronation of Queen Elizabeth I's coronation in Jan. 1559; and in the following July he returned to Ireland with a fresh commission, now as lord lieutenant, from the new queen, whose policy required him to come to terms if possible with the troublesome leaders of the O'Neills and the MacDonnells. Sussex was recalled, at his own request, in Oct. 1565. His government of Ireland had not, however, been without fruit. Sussex was the first representative of the English crown who enforced authority to any considerable extent beyond the limits of the Pale.

On his return to England, Sussex immediately threw himself into opposition to the earl of Leicester. In 1566 and the following year Elizabeth employed him in negotiations for a marriage with the archduke Charles. When this project failed Sussex returned from Vienna in March 1568. In July he was appointed lord president of the council of the north and in 1569 lord lieutenant of the north in which office he had to deal with the rebellion of the earls of Northumberland and Westmorland. In 1570 he laid waste the border, invaded Scotland, and raided the country round Dumfries, reducing the rebel leaders to complete submission. In December he became a privy councillor and in July 1572 lord chamberlain. He was henceforth in frequent attendance on Queen Elizabeth both in her progresses through the country and at court. He favoured her proposed marriage to Francis, duke of Anjou, and was an advocate of a conciliatory policy toward Spain. He died in London on June 9, 1583.

The earl of Sussex was a patron of literature and of the drama. He was twice married: first to Elizabeth, daughter of Thomas Wriothesley, earl of Southampton; and secondly to Frances, daughter of Sir William Sidney. His second wife was the foundress of Sidney Sussex college at Cambridge, which she endowed by her will. The earl left no children, and at his death his titles passed to his brother Henry. (R. B. Wm.)

**SUSSEX**, a county of southern England bounded on the south by the English Channel, on the west by Hampshire, and on the north by Surrey and in part by Kent, which bounds it on the east. The geographical area is 1,457 sq.mi. (3,774 sq.km.).

**Physical Geography.**—From the chalk hills of the western border, the South Downs (average height 500 ft. [150 m.]; Ditchling Beacon, 813 ft. [248 m.]) lead east-southeast to meet the sea between Brighton and Eastbourne as bold cliffs, notably Beachy Head. Farther east, between the rich alluvial pastures of Pevensey Levels and Walland Marsh (part of Romney Marsh), the Hastings Sands reach the sea, stretching back in a broken range northwest to the Forest Ridge of Ashdown Forest (837 ft. [255 m.]) at Crowborough and St. Leonard's Forest. The South Downs slope gently to the south, with zones of greensand and gault leading to a belt of fertile brick-earth loam extending from near Shoreham-by-Sea to Hampshire and broadening out south of Chichester into the flat headland of Selsey Bill. The northern slopes of the Downs are abrupt, and there the greensand and gault belts lead to the heavy clay of the Weald (*q.v.*). The coastline has changed within historic times, the land being constantly eroded by the sea, particularly around Selsey, where the site of the Saxon cathedral is now probably a mile out to sea. The lagoon of Pagham Harbour was partly reclaimed at an early date but was inundated by the sea about 1300, recovered in 1876, and again lost to the sea in 1911. The drift of shingle tends to force eastward the mouths of the rivers that rise in the Forest Ridge and flow south through gaps in the Downs, but new outlets have in some instances been made by storms, as at Newhaven in c. 1590, or by dredging, as at Shoreham-by-Sea in 1815. Wide deposits of shingle now separate the sea from the medieval ports of Winchelsea and Pevensey.

(L. F. S.)

**Archaeology.**—The influence of geology on the distribution of human activities at different stages of culture is striking, and Sussex has an important record of prehistoric sites and discoveries. The Paleolithic period is poorly represented, especially since the Piltdown discoveries, world famous for 40 years, were proved fraudulent in 1953. A few implements have been found in the raised beaches, especially at Slindon, and in the river gravels near Pulborough. The Mesolithic food-gatherers left a scatter of remains along the sand ridges of the Weald and on Tertiary deposits near Peacehaven. Primitive agricultural communities from the Neolithic to the Roman period preferred the chalk, though they hunted in the Weald. Four of the rare Neolithic "causewayed camps" lie on the Downs, the two larger ones being at Whitehawk (Brighton racecourse) and the Trundle (inner ring) at Goodwood. There is also a group of flint-mining sites near Worthing, including the well-known Cissbury and Harrow Hill flint mines. The Early and Middle Bronze Ages are poorly represented but include bell barrows on Bow Hill and on Monkton Down, Treyford.

as well as the vanished Hove Barrow, which yielded a magnificent amber cup and other objects. Remains of the Late Bronze Age are abundant, including several examples of the earliest identifiable farm sites with their field systems, notably at Plumpton Plain near Brighton, New Barn Down near Worthing, and Itford Hill near Lewes. Many bronze implements have been found, singly and in hoards, as well as gold ornaments, including the lost Mountfield treasure near Battle. The Iron Age is notable for the hill forts on the Downs, especially the Trundle (outer ring) at Goodwood, Cissbury near Worthing, and the Caburn near Lewes. The first two were constructed perhaps in the 3rd century B.C. and abandoned before the Roman occupation; the Caburn was rather later and appears to have been captured by the Romans soon after A.D. 43. Farm sites of the Iron Age have been found on Park Brow near Cissbury and elsewhere, and many gold coins of the Belgic kings of the Commius dynasty have been found at Selsey.

(ET. C. C.)

**History.**—About the beginning of the Christian era a dynasty of British chieftains was established in the peninsula of Selsey. When the Romans invaded Britain in A.D. 43, the last of these chiefs, Cogidumnus, proved so useful an ally that he was made *legatus*, or official administrator, and given an extended kingdom (*regnum*). His centre, Noviomagus (Chichester), was developed as a tribal capital by the Romans, who made a great road (Stane Street) to London and others to Calleva (Silchester) and Venta Belgarum (Winchester), and minor roads connecting the downland corn districts and the Wealden iron mines with London. The fertile coast and downland area west of the Pevensey lagoons was developed with many villas or large farms. During the 3rd and 4th centuries fortresses were built for defense against pirates, one being at Anderida (Pevensey, where half the 20-ft. [6 m.] high walls still stand). After the Roman troops left Britain, about A.D. 410, civilization decayed, and in 477 a band of Saxons under Aella (Ella) and his three sons landed near Selsey and occupied the country, slowly fighting their way eastward until in 491 they stormed the last stronghold of Andredesceaster—usually assumed to be Pevensey—and massacred its defenders. The South Saxon conquest seems to have been ruthless and complete: no Celtic place-names survived, except those of three rivers—Tarrant (later Arun), Lavant, and Limene (later Rother). Aella's son Cissa probably occupied the walled Roman city called Chichester after him, but Sussex, the land of the South Saxons, soon fell under the control of Wessex, except for a (probably later) settlement in the east near Hastings, which seems to have retained some independence until 1011, when the Danes are said to have overrun it and the rest of Sussex.

In 681 Aethelwulf, one of the semi-independent kings, received the exiled Bishop Wilfrid, gave him large estates, and encouraged or ordered his subjects to accept Christianity. Wilfrid established a monastic bishopric at Selsey, and during the next two centuries churches were built and endowed throughout the county. Estates on the coast of Sussex were granted to Norman monasteries, notably to the abbey of Fécamp. In 1066, when Harold II was elected king, William I landed at Pevensey and marched to Hastings, near which town the decisive Battle of Hastings was fought on Oct. 14. On the site William built his votive Battle Abbey. Probably in order to secure his communications between Normandy and London, William divided Sussex into five blocks, each running from the coast, with a port, to the northern bounds of the county. Each of these districts, known as rapes, *i.e.*, districts that were "roped off," was in the hands of a trusted Norman lord, whose castles were built at Hastings, Pevensey, Lewes, Bramber, and Arundel. Later, about 1250, a sixth rape, Chichester, was separated for administrative purposes from Arundel. In the Domesday Book of 1086 the liberty of the abbot of Battle is also called a rape, but in all other records it is called the lowy. The boundaries of the rapes ran roughly parallel from north to south, and each rape contained a river, a castle, and a forest. From Domesday it is clear that the northern boundary of Sussex was still uncertain and that scarcely any villages existed in the wooded districts of the Weald, though many areas there were attached to manors in the settled south, serving at first as pastures for swine

but being gradually cleared and settled. In 1086 the chief towns were Chichester, to which city the cathedral see had been moved from Selsey in 1075, and Lewes, which as early as 930 had been one of the few boroughs in England to be allowed two mints. Of Hastings, then an important harbour and one of the Cinque Ports (*q.v.*), no details are given. The Norman Conquest brought much building of churches and the foundation of the great Cluniac priory of Lewes and of "alien priories" (cells of Norman abbeys) at Boxgrove, Sele, and Wilmington.

During the reign of Henry III the see of Chichester was occupied by Bishop Richard de Wyche, whose saintly character led to his canonization in 1262, the shrine of St. Richard in the cathedral becoming a centre of pilgrimage. Although the castles of Sussex were held by supporters of King Henry III, it was on the Downs above Lewes that the royal forces were decisively defeated by Simon de Montfort in 1264; but Pevensey Castle held out until the king was restored to power. About this time a series of storms damaged the Cinque Port of Hastings and threatened to destroy the "ancient town" of Winchelsea. Accordingly, Edward I removed the inhabitants of Winchelsea to a safer site, where he laid out a town on a plan of rectangular blocks. The coast, however, soon suffered other assaults, the Hundred Years' War bringing constant raids by the French, who burned Hastings, Rye, and Winchelsea. The plague known as the Black Death hit the county heavily in 1349, killing about a third of the population, and there were further outbreaks in 1361 and 1366. Distress and misgovernment led the men of Sussex to support the Peasants' Revolt in 1381 and to take a prominent part in Jack Cade's Rebellion in 1450.

The Tudor period brought increased prosperity, but its importance in Sussex lies mainly in the realm of religion. On the whole, Sussex accepted the Protestant reform, so much so that during the short reign of Mary I, 30 men and women were burned, at Lewes and elsewhere, as heretics. The memory of these martyrs gave a strongly antipapal, and later puritan, tinge to popular feeling, though there were pockets of Roman Catholicism in the county. The county was therefore predominantly on the side of the Parliament during the Civil War, though Arundel Castle and the city of Chichester were for a time held for the king, and it was from Brighton that Charles II escaped to France after his defeat at Worcester. Puritan tendencies in the diocese are shown by the resignation or expulsion of more than 60 incumbents under the Act of Uniformity in 1662 and by the growth of the Quakers in spite of persecution.

During the last quarter of the 18th century, troubles with France led to the formation of local volunteers, and the movement was speeded up by the French Revolution, many of whose victims sought shelter in the Sussex coastal towns. A great camp was established in 1793 on the Downs near Brighton, and others near Eastbourne and Bexhill; when Napoleon I threatened invasion the coast was fortified by a chain of Martello towers, of which the westernmost was at Seaford. Brighton had since 1750 been developing into a fashionable watering place, especially from the first visit (1783) of the Prince Regent (afterward George IV) and the building of the Royal Pavilion. With the cult of sea bathing other towns developed at Bognor (*see* BOGNOR REGIS), Hastings (*q.v.*), and St. Leonards, Eastbourne (*q.v.*), and Worthing (*q.v.*).

The growth of coastal resorts, the urbanization of almost the whole coast, and the conversion of much of it into "dormitory towns" for London were the main features of the history of Sussex after the beginning of the 19th century.

**Architecture.**—Of monastic remains the chief are those of Battle Abbey, with its splendid gatehouse, Bayham Abbey, and Lewes Priory. Extensive remains of Robertsbridge Abbey and of the Augustinian priories of Michelham and Shulbrede and the alien priory of Wilmington are incorporated in modern houses. The friary chapels of Chichester, Winchelsea, and Rye are important, as is the medieval hospital of St. Mary at Chichester. Sussex is rich in churches built before or shortly after the Norman Conquest, such as Bosham, Sompting, and Worth. There are many mural paintings; an early group arose under the influence of Lewes Priory.

Pevensey Castle, built within the impressive walls of a Roman

fortress, has an early Norman keep but was mostly built about 1250. At Lewes the early keep and later barbican are noteworthy; at Arundel only the keep is ancient, and Hastings and Bramber are mere fragments. Amberley Castle dates from 1377 and the lovely moated castle of Bodiam from 1386. Herstmonceux Castle (now occupied by the Royal Observatory), a brick building completed c. 1444, was rather a defensible great house than a true castle, in this resembling the ruined early Tudor house of Cowdray. Of later great houses, Parham, Petworth, and Up Park (the last two belonging to the National Trust) are outstanding. But it is in its wealth of minor houses that Sussex is particularly strong. The medieval examples are mostly timber framed; later building is mainly in brick, e.g., at Chichester and Lewes; and the good tradition, come down through the charming Regency buildings of Brighton, was revived in the planning of many council estates. (See also ARUNDEL; BATTLE; BEXHILL; BRIGHTON; CHICHESTER; HASTINGS; HERSTMONCEUX; LEWES; PETWORTH; PEVENSEY; RYE; SEAFORD; SHOREHAM-BY-SEA; WINCHELSEA.)

**Population and Administration.**—At the first census in 1801 the population was, in round figures, 159,500; in 1851, 337,000; in 1901, 605,000; in 1951, 937,339; and in 1961, 1,077,517 (East Sussex 665,904, West Sussex 411,613). The respective figures for Brighton were: 7,300; 65,500; 102,300; 156,486; 163,159; and for Hove: 100; 4,100; 29,700; 69,535; and 72,973, showing the progressive urbanization of the county. In East Sussex are three county boroughs: Brighton, Eastbourne (1961, 60,918), Hastings (66,478); four municipal boroughs: Bexhill (28,941), Hove, Lewes (13,645), Rye (4,438); and six urban and five rural districts. West Sussex has three municipal boroughs: Arundel (2,617), Chichester (20,124), Worthing (80,329), and five urban and six rural districts. Crawley (*q.v.*) New Town, designated in 1946, had a population of 54,047 in 1961.

The formation of the two administrative counties of East and West Sussex in 1889 regularized a division that is traceable in Saxon times, corresponding to the two archdeaconries of Lewes and Chichester. The creation of five rapes, each originally with its own sheriff in addition to the king's sheriff of the whole county, obscured this division, but a long struggle over whether the County Court should be held at Chichester or Lewes was compromised in 1504 by an order for alternate sessions. From the reign of Elizabeth I, Quarter Sessions records were kept separately for East and West Sussex, with one joint session yearly. After the grant of the honour of Pevensey to John of Gaunt in 1372, this district became part of the duchy of Lancaster; the privileges of the manor of Bosham and of the Cinque Ports, the ecclesiastical lwy of Battle Abbey, and the peculiars of the archbishop of Canterbury complicated the medieval jurisdiction of the county.

From 1295, members of Parliament were returned more or less regularly by the city of Chichester and the boroughs of Arundel, Bramber, East Grinstead, Horsham, Lewes, Midhurst, Shoreham-by-Sea, and Steyning, and the Cinque Ports of Hastings, Rye, Seaford, and Winchelsea. Many of these constituencies were small and very corrupt, and under the Reform Act of 1832 five lost both members and four lost one, but Brighton was assigned two members. There are four county and four borough constituencies in East Sussex. West Sussex returns four members to Parliament. Brighton returns two members, Eastbourne one, and Hastings one. The University of Sussex was founded at Brighton in 1961, with its headquarters in the 18th-century Stanmer House.

**The Economy.**—Sussex is still heavily wooded; in early times the Weald was tree covered, the clay producing oaks and the lighter soils favouring beech. The small fields there became good corn-growing areas, after improved drainage was provided. Most arable land, however, has always lain on chalk and greensand and along the coastal plain. This last, especially near Worthing, became a centre of market gardening. Hops are grown in the east, though less widely than formerly. Under John Ellman of Glynde between 1780 and 1830 the breed of Southdown sheep became famous, but since 1870 sheep have almost vanished from the Downs. Cattle have increased, particularly for dairy herds, and the rearing and fattening of poultry is also an active industry. Nor is the harvest of the sea negligible, though less important than in

medieval times, when Winchelsea was famous for plaice, Arundel for mullet, and Selsey for cockles, and the Cinque Ports were as much concerned with herring as with naval transport and piracy.

The sea was once the source of the salt industry; a quarter of all salt pans recorded in Domesday Book were in Sussex. Salt boiling depended on fuel, and the Sussex woods supplied fuel also for glassworks round Kirdford and Wisborough Green from the 13th to the 17th century, as well as for pottery, tile, and, later, brick kilns. Sussex oak was in demand for naval and other shipbuilding. The plentiful supply of fuel and iron ore made the county a centre of the iron industry from Roman times until the end of the 18th century. From Tudor times Sussex cast-iron ordnance, as well as domestic objects, were in demand; but when it became possible to use pit coal for smelting, the industry moved north to the coal-fields.

Although the Weald was not impenetrable, Sussex roads were notoriously bad, and in winter often impassable, until the coming of turnpike roads toward the end of the 18th century. A railway from London to Brighton was opened in 1841, and the county is now served by the Southern Region of British Railways. A regular cross-channel service to Dieppe is maintained from Newhaven.

Kingley Vale and Lullington Heath are nature reserves; 10,618 ac. (4,297 ha.) of Sussex were owned by the National Trust in 1963 and 1,414 ac. (572 ha.) protected; 15 areas belonged to the Forestry Commission.

**SUSSEX, KINGDOM OF** (*Suð Seaxe*, i.e., the South Saxons), one of the kingdoms of Anglo-Saxon Britain, the boundaries of which coincided by the end of the period with those of the modern county, though as late as 1011 a distinction can be drawn between Sussex and Hastings; i.e., an area of East Sussex whose name survives as that of a town. According to the tradition given in the *Anglo-Saxon Chronicle*, a certain Aelli and his three sons landed in 477 at Cymenesora, a place now covered by the sea, south of Selsey Bill, and defeated the Britons. He fought again in 485 near a stream called Mearcresdesburne and in 491, with his son Cissa, captured Anderida (Pevensey) and killed all the inhabitants. Bede names Aelli as the first king of the English to hold a supremacy over all the peoples south of the Humber. No later king of Sussex held this eminence.

The history of Sussex is then blank for about two centuries except for a war with Ceolwulf of Wessex in 607. In 681 Bishop Wilfrid, expelled from Northumbria, went to Sussex. He found the people heathen, though their king, Aethelwath, had been baptized in Mercia and had been given by his sponsor, King Wulfhere, the Isle of Wight and the district about the River Meon in Hampshire. Wilfrid stayed five years converting the South Saxons. He received a grant of 87 hides at Selsey for a monastery, and this became the episcopal see for the South Saxons, probably about 709. The see was moved to Chichester after the Norman Conquest.

At the end of 684, the South Saxons sent an army to help a Kentish aetheling, Eadric, to drive out his uncle King Hlothhere. Soon after, a West Saxon exiled prince, Ceadwalla, ravaged Sussex and killed King Aethelwath, and, though he was then driven out, he subjugated Sussex after he became king of Wessex in 685. Sussex was later divided among several kings. One called Nothhelm, or Nunna for short, made in 692 a grant to his sister Nothgith that was witnessed by a King Watt; a later charter of Nunna is witnessed by King Aethelstan and Queen Aethelthryth, and another by King Aethelberht. Nunna is described as a kinsman of one of Wessex, when in 710 he helped him fight Geraint, king of the West

Welsh; but Ine fought against the South Saxons, who were harrying a West Saxon aetheling, Ealdberht, in 722 and again in 725, when he killed Ealdberht. There were still kings in Sussex early in the reign (757–796) of Offa of Mercia; he confirmed between 757 and 770 grants by kings called Aldwulf and Osmund; Aldwulf's charter is witnessed by a King Aethwald and, probably, a King Oslac, though the name is bungled. Later, however, Aldwulf, Osmund, and Oslac attest as *duces* (ealdormen), and no further mention is made of kings. Offa captured the area of Hastings in 771. In 825 the South Saxons submitted to Egbert of Wessex, and henceforth were ruled by West Saxon kings. Sussex sometimes had an ealdorman of its own. It was divided into rapes, which, although they are not mentioned in pre-Conquest sources, are held to be very ancient administrative divisions.

(D. Wk.)

**SUSU**, a Negro people of West Africa living in the coastal regions of southern Republic of Guinea (250,000) and the northwestern parts of Sierra Leone (50,000 in the 1960s). Their language is classed with the Mande-fu group (see **MANDINGO**), but ethnically there appear to be three stocks: Dialonke, deriving from the indigenous peoples expelled from Fouta Djallon by the Fulani (q.v.); a very old semi-Bantu stock linked with Baga, Landuman (q.v.), Nalu, and Mandeniyi; and a Mandingo stock probably of more recent origin.

From what is known of these tall, slender people authority would seem to be vested in a family head (*kabilé koundji*), rather than in a village chief. In Sierra Leone villages are grouped under a paramount chief into small chiefdoms (of about 3,000–6,000 people each) represented on district councils. Every Susu belongs to one of the patrilineal clans identified by name and totem animal. Marriage between cross-cousins is favoured, and polygynous unions are common. Shoemakers, jewelers, musicians, smiths, and carpenters used to constitute separate castes and were said to be descended from slaves. There were no marriages between them and members of free lineages, but such restrictions are of little importance now. Traditionally the Susu were animists but are now largely Muslim.

(M. P. Bn.)

**SUTHERLAND, EARLS AND DUKES OF.** From the time of its creation in the 13th century, the Scottish title of earl and later of duke of Sutherland has been held in the same family, although twice descending through the female line. The first earl is generally held to have been WILLIAM (d. c. 1248), whose father, Hugh Freskin (d. c. 1214/22), had large possessions in Sutherland before 1211. William was probably created earl in 1235. His great grandson WILLIAM (d. c. 1370), 5th earl, married Margaret, daughter of Robert I, the Bruce, and sister of David II. He fought against the English at the Battle of Neville's Cross (1346) and in 1357 was a hostage for the payment of the ransom for David, who had been captured at the battle. William's descendant JOHN (d. 1514), 9th earl, died unmarried and was succeeded by his sister and heir ELIZABETH (d. 1535), countess of Sutherland, wife of ADAM GORDON (d. 1538), the second son of George Gordon, 2nd earl of Huntly. Adam was styled earl of Sutherland from 1515 by right of his wife. He was succeeded by his grandson JOHN (1525–67), 11th earl, known as "the Good Earl John," who was poisoned by Isabel Sinclair, widow of his uncle Gilbert Gordon of Garty, in an attempt to secure the earldom for her son. She failed, however, to poison John's son ALEXANDER (1552–94), who succeeded as 12th earl.

Alexander's grandson JOHN (1609–79), 14th earl, was a leader of the Covenanters and fought against the marquess of Montrose at the Battle of Auldearn in 1645. He was keeper of the privy seal in Scotland (1649–51). His grandson JOHN (1661–1733),

16th earl, supported the Revolution in 1688 and was a commissioner in 1706 for the union of England and Scotland. In 1715 he became lord lieutenant of the six northern counties of Scotland and was active in putting down the Jacobite Rebellion in that year. About 1690 he took the surname of Sutherland instead of Gordon. He was succeeded by his grandson WILLIAM (1708–50), 17th earl, who helped suppress the Jacobite Rebellion of 1745.

His son WILLIAM (1735–66), 18th earl, died without male issue, and in 1771 the House of Lords confirmed the claim of this William's second daughter, ELIZABETH (1765–1839). She married in 1785 GEORGE GRANVILLE LEVESON-GOWER (1758–1833), who succeeded his father as 2nd marquess of Stafford in 1803. In addition to the estates of this title, he also inherited the Bridgwater Canal and estates from his maternal uncle Francis Egerton, 3rd duke of Bridgwater, and these properties, together with his wife's estates, made him a "leviathan of wealth" (Charles Greville, *Memoirs*, 1st series, [1874], vol. iii, p. 19). An "improving" landowner, he constructed roads and bridges in Sutherland and was also responsible for the Sutherland clearances, establishing extensive sheep runs by removing large numbers of his tenants from the interior to new coastal fishing villages. This aroused much bitterness and criticism. He was created duke of Sutherland in 1833. His son GEORGE (1786–1861), 2nd duke, assumed the additional surname of Sutherland in 1841. On the death without issue of the 2nd duke's great-grandson, GEORGE (1888–1963), 5th duke, the dukedom passed to his kinsman, JOHN SUTHERLAND EGERTON (1915– ), 5th earl of Ellesmere, who was descended from the brother of the 1st duke; the earldom of Sutherland passed to the 5th duke's niece, ELIZABETH MILLICENT (1921– ).

See Sir Robert Gordon, *A Genealogical History of the Earldom of Sutherland . . . to the Year 1651* (1813).

**SUTHERLAND, GEORGE** (1862–1942), U.S. Supreme Court justice from 1922 to 1938, was often spokesman for the court when it nullified social legislation. Brought to Utah soon after he was born in Buckinghamshire, Eng., on March 25, 1862, Sutherland attended Brigham Young University and the University of Michigan Law School. He was admitted to the bar in 1883. Subsequently he settled in Salt Lake City and became active as a Republican in Utah politics, becoming in 1896 a member of the state senate. He was widely supported by members of the Church of Jesus Christ of the Latter-day Saints although he himself was not a member.

From 1901 to 1903 Sutherland was a member of the U.S. House of Representatives, and from 1905 to 1917 he served in the U.S. Senate, his principal legislative accomplishment being the impetus he gave to the 19th (woman suffrage) Amendment to the U.S. Constitution. He was an ardent exponent of workmen's compensation and legislation for the benefit of seamen. In the 1920 presidential campaign and thereafter until his appointment to the court in 1922, he was an intimate adviser of Pres. Warren G. Harding. On the court, Sutherland quickly became identified with the conservative majority, writing the opinion outlawing the minimum wage (*Adkins v. Children's Hospital*, 261 U.S. 525 [1923]). Paradoxically, despite his hostility to governmental action, his most enduring contribution is probably his conception of the foreign relations power; it was, he successfully argued, not subject to the usual constitutional limitations (*U.S. v. Curtiss-Wright Export Corp.*, 299 U.S. 304 [1936]). He retired from the Supreme Court on Jan. 5, 1938, and died on July 18, 1942, in Stockbridge, Mass.

See J. F. Paschal, *Mr. Justice Sutherland* (1951). (J. F. Pl.)

**SUTHERLAND, GRAHAM VIVIAN** (1903– ), English painter, whose imaginative landscapes and other works can be seen in galleries throughout the world, was born in London on Aug. 24, 1903. His early work as an etcher and engraver owes much to the romantic painter Samuel Palmer, but he was influenced at different times by the work of William Blake, Paul Nash, Henry Moore, and Picasso. It was not until 1935, after a visit to Wales, that he decided to become a painter. Although primarily interested in landscape, Sutherland's best-known works are remarkably diverse. His paintings as an official war artist (1941–44) provide a record of desolation both factual and evocative. His "Crucifixion" of 1946 in St. Matthew's Church, Northampton, uses the

thorn motif, which recurs frequently in later work, for its expressionistic power, while the hard spiky shapes of fossils provided the theme of his large "Origins of the Land," painted for the 1951 Festival of Britain. His portrait of Somerset Maugham (Tate Gallery, London, 1949) was the first of a short but impressive series of portraits. In 1954–57 he designed the enormous tapestry for the new Coventry Cathedral. Important retrospective exhibitions were held at Venice (1952), London (1953), and Turin (1965).

**BIBLIOGRAPHY.**—E. Sackville-West, *Graham Sutherland*, 2nd ed. (1955); Robert Melville, *Graham Sutherland* (1950); D. Cooper, *The Work of Graham Sutherland* (1961). (D. L. Fr.)

**SUTHERLAND**, a county of Scotland, forms an irregular pentagon with its apex pointing into the Atlantic at the Cape Wrath cliffs, the northwesterly point of the Scottish mainland. From Cape Wrath the rugged and indented north coast runs east to the eastern boundary with Caithness and the somewhat similar but island-girt west coast runs southwest to the southern boundary with Ross and Cromarty. The fifth, southeastern, side is the North Sea shore running northeast-southwest, gentler and indented only in Dornoch Firth at the southern boundary and in the partially reclaimed Loch Fleet. The land area is 2,028 sq.mi. (5,253 sq.km.).

**Physical Characteristics.**—Mean annual rainfall in the east is about 25–30 in. (640–760 mm.), with dry springs; it rises gradually to 80–90 in. in the western Highlands, declining to 40 in. on the littoral. Associated contrasts in landscape from east to west include: (1) a narrow coastal belt of arable stock farms and estate woodlands mainly on postglacial raised beaches, etc., and on the downfaulted Jurassic marls, limestones, and coal around Brora; (2) hills of granite (Ben na Meilich, 1,940 ft. [590 m.]) or Old Red Sandstone conglomerate (Beinn Dhorain, 2,060 ft.) clad in heather—*naidus* moor; (3) a belt 30–40 mi. (48–64 km.) wide of bleak moors at 500–1,000 ft. planed across metamorphic Moine (Gaelic "moorland") schists, the root of Caledonian folding—this surface cut by glens, molded by ice, some a ribbon lake (Loch Shin), some with glacial and fluvio-glacial deposits carved by modern streams (e.g., near Inchnadamph); above the main moorland surface stand isolated hills in schists (Ben Hope, 3,040 ft.) or granite (Ben Loyal, 2,504 ft.); (4) a series of narrow north-south belts in the west: the Moine thrust plane from Loch Eriboll to Loch Ailsh in Glen Oykel, bounding the schists to the east and, to the west, the white Cambrian quartzites and scarped, sweet-grassed Durness limestone, the massive red-brown Torridonian sandstone, and the ice-scoured hummocks and lochans (small lochs) of the Archean Lewisian Gneiss. This complex zone includes the Ben More Assynt massif (3,273 ft.; 998 m.) of Lewisian Gneiss capped by gleaming Cambrian quartzite, and was a major centre of dispersal of Quaternary glaciers; each rock type contributes distinctively to the scenery, lower slopes carrying extensive acid sheep pastures (fescue-purple moorgrass). Fauna includes red deer, pine marten, wild cat, and ptarmigan, with salmon in the prized and high-rented streams; (5) a coast with spectacular cliffs (Cape Wrath), sea-lochs, and sandy bays.

**History.**—There are in Sutherland a number of prehistoric remains, comprising chambered cairns, both round and horned, standing stones and stone rows, hill forts, settlements, and brochs (round towers). The majority are situated in the southeast of the county, in particular near the Dornoch Firth but also northward up the coast as far as Helmsdale. Other groups are on the north coast, near Bettyhill, Tongue, and Portskerra; and in the west, near Inchnadamph, Lochinver, and Scourie.

Near Inchnadamph, on the northern side of Loch Assynt, is the ruined Ardvreck Castle, in which James Graham, marquess of Montrose (q.v.), was held for a few days in 1650 by Neil Macleod of Assynt who betrayed him to the Covenanters.

In the first half of the 11th century, Sutherland and Caithness were held by Thorfinn (d. c. 1065), the Norse jarl of Orkney, whose mother was a daughter of the Scottish king Malcolm II. It was the Norse who named the area (in relation to their settlements in Orkney and Shetland) *Sudrland* (southern land). After conquering the district, King William the Lion (reigned 1165–1214)

seems to have granted land in Sutherland to a Hugh Freskin, whose son William was probably created earl in 1235. For the change of the family name of the earls, first to Gordon in 1515 and then to Leveson-Gower in 1785, see SUTHERLAND, EARLS AND DUKES OF.

George Granville Leveson-Gower (1758–1833), who had married (1785) Elizabeth (countess of Sutherland in her own right), succeeded his father as marquess of Stafford (1803), and was created duke of Sutherland (1833), was responsible for the notorious Sutherland Clearances (c. 1810–20), though also for road building. Advised that the interior of Sutherland was best suited for sheepraising and little fit for human habitation, he evicted thousands of families, burning their cottages and establishing large sheep farms. The evicted tenants were resettled in small coastal crofts, where their livelihood was to depend upon fishing and kelp-burning (until the latter was brought to an end by the development of the alkali industry). From the time of the potato famine of 1846, emigration has been continuous, despite various measures designed to help the crofters. Karl Marx in *Das Kapital* gave a striking, though polemical, description of these events.

**The Economy.**—Only about 1½% of the total area is arable, the lowest proportion in Scotland. The best land adjoins Dornoch Firth, where farming is advanced and on fertile valley flats. Crofters still predominate, and the average holding of crops and grass (i.e., rough grazings excluded) is 14 ac. (5.7 ha.), the smallest in Scotland excepting the Shetland Islands. Oats, turnips, swedes (rutabagas), and potatoes are grown. The raising of sheep, mostly Cheviot, is the county's staple business, and cattle are also kept. Next to agriculture, the sea fisheries and the salmon fisheries in the estuaries are the most important industries. Kinlochbervie and Lochinver are west-coast fishing ports, mainly for herring. Brora makes whisky, woolens, and bricks, and some coal is mined. The extensive deer forests and grouse moors and lochs and rivers attract many sportsmen; Dornoch (q.v.), Lochinver, Golspie (q.v.), and Brora are holiday resorts.

The railway enters the county from Ross and Cromarty at Invershin and leaves it for Caithness beyond Forsinard. Glasgow steamers call at Lochinver about every ten days.

**Population and Administration.**—The population in 1921 was 17,802; in 1961 it was 13,507, of whom 2,349 spoke Gaelic and English and 5 Gaelic only. The population density is the lowest in Scotland. Dornoch (pop., 1961, 933) is the county town and the only burgh; the county offices are at Golspie. There are six county districts. The shire (with Caithness) returns one member to parliament and forms a joint sheriffdom with Ross and Cromarty, with a sheriff-substitute resident at Dornoch.

**SUTLEJ** (ancient Greek ZARADROS, Vedic SUTUDRI or SARADRU), one of the "five rivers" of the Punjab, rises in southwestern Tibet in Rakas Tal Lake (which receives water from Manasarovar Lake lying just to the east), at an elevation of more than 15,000 ft. (4,600 m.). It threads its way in a northwesterly direction through the Himalayan gorges, with heights of 20,000 ft. (6,000 m.) on either side, crosses the Indian union territory of Himachal Pradesh, and enters the Hoshiarpur district of Punjab. Thence it flows through the plains of the Punjab, receiving the Beas on its north bank in the southwest of Kapurthala district and forming for 65 mi. (105 km.) the Indo-Pakistan frontier before entering West Pakistan. It joins the Chenab (q.v.) 40 mi. (64 km.) W of Bahawalpur after a course of 850 mi. (1,368 km.). The two rivers there form the Panjnad ("five streams"), the link between the five rivers and the Indus.

As the river flows through an area of precarious rainfall, dams have been built all along it. Works include the Bhakra-Nangal multipurpose project; the Sirhind Canal; and, below Ferozepur, on both banks in India and Pakistan, the Sutlej Valley Project. Of the five rivers it has the largest catchment area (18,500 sq.mi.)

[47,900 sq.km.]], but in relation to its size the poorest discharge. From 1947 until the agreement between India and Pakistan in 1960 the use of the Sutlej waters was a source of serious friction.

(L. D. S.)

**SUTO** (BASUTO); the occupants of Lesotho (formerly Basutoland) and neighbouring areas in South Africa. They are not all of one ethnic stock but consist of those who accept the authority of the paramount chief or king of Lesotho. The Basuto nation was created by the chief Moshoeshe (known to Europeans as Moshesh) in the 19th century (see *LESOTHO: History*). The majority are of southern Sotho linguistic stock, with a small minority from the Nguni-speaking tribes (about 15%). By the early 1960s they numbered about 500,000, though about 45% of the adult males were absent from the country as labour migrants.

The people live in small hamlets, which are grouped into parishes under hereditary headmen possessing administrative and judicial powers. Parishes are grouped into chiefdoms with hereditary chiefs, and these form provinces under chiefs, most of whom are close kin of the paramount. Authority at all levels is held by the genealogically senior man of the patrilineal line of descent that is regarded as the founding line of the settlement or chiefdom, the members of which regard their chief as a senior kinsman rather than as a mere administrative official.

The paramount is the senior patrilineal descendant from Mamohate, the senior wife of Moshoeshe. He is advised both by a council of his close kin and by the national assembly, the *pitso*. He acts as head of the nation in all affairs, as final court of appeal and as ritual guardian of the country.

Corn (maize) is the staple food of the people; sorghum in the lowlands and wheat in the mountain areas are also important crops.

Initiation and formal instruction at puberty are practised, but the Basuto have no age-set system. Marriage is by transfer of bridewealth and cross-cousin marriage is preferred, although marriage with a parallel cousin is also permitted.

Most Basuto have become Christian. The central feature of the traditional religion is a cult of ancestors worshiped by their descendants. Modern cultists believe in a supreme being, but this is probably taken from Christian missionaries. See also *AFRICA: Ethnography (Anthropology): Southern Africa; LESOTHO: The People*.

(J. F. M. M.)

**SUTTEE** (SATI), the former Indian custom of immolating a widow along with her dead husband (*saha-marana*) or soon after his death (*anu-marana*); sometimes the wife was immolated before the husband's expected death in battle (*jauhar*). The Indian term *sati* means "chaste wife" and does not refer to the act of immolation. The custom probably originated in the belief that the great ones needed their companions in the afterlife as well as in this world. It was thus originally confined to royalty and nobility, and it never became a common practice. The first reference to it in a Sanskrit text is in the *Mahabharata* (c. A.D. 400), where some queens undergo *sati*; but it is mentioned by the 1st-century B.C. Greek author Diodorus Siculus in his account of the Punjab in the 4th century B.C. That it was practised among royalty and the fighting classes from c. A.D. 500 is confirmed by extant *sati* stones, memorials to widows who died in this way.

In the Muslim Period the Rajputs practised *jauhar* to save the women from dishonour by foes (see *CHITTORGARH*). The larger incidence of *sati* among the Brahmins of Bengal, particularly during 1680–1830, was due indirectly to the *Dayabhaga* system of law (c. 1100 A.D.), which prevailed in Bengal and which gave inheritance to widows. At its best *sati* was committed voluntarily on the widow's part, but cases of compulsion, escape, and rescue are known. Steps to prohibit it were taken by the Mogul rulers Humayun and his son Akbar, and it was abolished in British India by Lord William Bentinck in 1829. Instances of it continued to occur in Indian states for more than 30 years.

See Edward Thompson, *Suttee* (1928).

(Vz. R.)

**SUTTER, JOHN AUGUSTUS** (1803–1880), pioneer settler in California on whose land gold was discovered in 1848. He was born Feb. 15, 1803, in Kandern, in the Grand Duchy of Baden, of Swiss parentage. He went to America in 1834, fleeing from bankruptcy and abandoning his wife and children. After traveling widely and experiencing further financial failures he reached California in 1839. By sheer charm and vivacity, supplemented by a claim to military rank that never existed, he persuaded the Mexican governor to grant him lands on the Sacramento River, where he was to establish a fortified settlement. There, at its junction with the American River, he established New Helvetia, later to become the city of Sacramento. He built "Sutter's Fort," set up frontier industries, cultivated the land, and increased his herds. His debts were enormous and his tenure precarious, but when trappers and immigrants came to his fort they were received with lavish hospitality.

At the outbreak of the war with Mexico (1846) the fort was taken over by U.S. forces commanded by John C. Frémont, who was unappreciative of Sutter's former kindness to American settlers. Sutter, nevertheless, gave invaluable aid to the conquerors and became an American citizen. Then, just as his fortunes seemed restored, the discovery of gold on his land ironically brought colossal disaster. On Jan. 24, 1848, James W. Marshall, who was building a sawmill for Sutter at Coloma, 50 mi. up the American River, arrived at Sutter's Fort and with great secrecy showed Sutter flakes of gold. The two men tried to keep the discovery secret but the news leaked out, and shortly there was wholesale desertion from New Helvetia, followed by swarms of gold seekers from San Francisco. Sutter saw his lands overrun, his herds slaughtered, and his property stolen. His downfall was completed when the courts denied title to his Mexican land grant. By 1852 he was bankrupt. There followed brief periods of hopefulness and illusory grandeur, but the rest of his life was one of continued disappointment and frustration. The family he had abandoned in Switzerland joined him after 16 years, only to share in his misfortunes.

Sutter died in Washington, D.C., on June 18, 1880, heartbroken at the failure of Congress to act for his relief. Sutter Street, in San Francisco, and Sutter County commemorate his name; in Sacramento there is a restoration of his fort.

**BIBLIOGRAPHY.**—J. A. Sutter, *New Helvetia Diary* (1939); Erwin G. Gudde, *Sutter's Own Story* (1936); J. P. Zollinger, *Sutter: the Man and His Empire* (1939).

(F. P. F.)

**SUTTNER, BERTHA FÉLICIE SOPHIE**, BARONESS VON (1843–1914), Austrian novelist, notable female pacifist, and winner of the Nobel Prize for Peace in 1905, was born at Prague on June 9, 1843, the daughter of Count Franz von Kinsky, Austrian field marshal. In 1876 she was hired as a secretary-housekeeper by Alfred Nobel, the munitions maker, but soon married Baron Arthur Gundaccar von Suttner, whose family disapproved of the match because she was seven years his senior and of a poor family. The couple lived at Tiflis in the Caucasus until 1885, when the Von Suttner family was reconciled to the marriage. Though she saw Nobel only twice more, she corresponded with him and is credited with influencing him in the establishment of the Nobel Prize for Peace.

Of her novels, *Die Waffen nieder!* (1889; best Eng. trans. by T. Holmes, *Lay Down Your Arms!*, 1892) was second in popularity in the 19th century only to Harriet Beecher Stowe's *Uncle Tom's Cabin*. *Das Maschinenzeitalter* (1899) reflects the scientific and free-thinking basis of her pacifism as derived from H. T. Buckle, Spencer, and Darwin. She founded the Austrian Society of Peace-Lovers in 1891 and edited the international pacifist journal *Die Waffen nieder!* from 1892 to 1899. She died in Vienna on June 21, 1914.

See Ellen Key, *Florence Nightingale und Baroness von Suttner* (1919); H. Schück et al. (ed.), *Nobel, the Man and His Prizes* (1962).

**SUTTON**, one of the 32 boroughs constituting Greater London, forms part of its southern perimeter. Area 16.7 sq.mi. (43.3 sq.km.); pop. (1961) 166,790. It is mainly residential but has some industries, including the manufacture of plastics, chemicals, radio components, and paper goods.

Historic buildings include All Saints Church at Carshalton, dating from the 12th century (restored 1893); the Lumley Chapel of the old St. Dunstan's Church at Cheam; Beddington Church (14th century); and the Great Hall of Beddington Place with a fine Tudor hammerbeam roof. In Cheam are a number of old timber-framed houses, including Whitehall (early Tudor).

The River Wandle rises in the borough and flows north to the Thames. Landscaped parks include Cheam Park (adjoining Non-such Park), and the Oaks, the estate once leased to the 12th earl of Derby which gave its name (1779) to the Oaks horse race. This, with the Derby (1780), is run annually on nearby Epsom racecourse. Within the borough is most of the former Croydon Airport, unused from 1959; the site is being developed as a residential neighbourhood. Sutton Station is an important suburban railway junction; and there are twelve other stations in the borough that provide rail links to Central London and the south coast. The southern terminus of the London Underground's Northern Line is at Morden, near the borough's northern boundary, which is approximately 12 mi. S of Charing Cross.

The London Borough of Sutton was created by Royal Charter in 1964 under the London Government Act 1963 (see LONDON) through the amalgamation of the former boroughs of Sutton and Cheam and Beddington and Wallington, and the urban district of Carshalton. These localities have long histories, and all appear in the Domesday Book. Medieval holders of manors were the Carew family (Beddington); the Dymoke family (Wallington); Christchurch Priory (West Cheam); the archbishop of Canterbury (East Cheam); and Chertsey Abbey (Sutton).

Distinguished residents were John Radcliffe (1650–1714), the well-known physician and benefactor to the University of Oxford; Philip Yorke, 1st earl of Hardwicke (1690–1764), the celebrated lord-chancellor; and Gen. John Burgoyne (1722–1792).

(T. M. H. S.)

**SUTTON COLDFIELD**, a municipal borough (1886) in the Sutton Coldfield Parliamentary Division of Warwickshire, Eng., 7 mi. NNE of Birmingham. Pop. (1961) 72,165. Area 21.8 sq.mi. It is a residential district with a few light industries, and the British Broadcasting Corporation's television transmitter mast (750 ft.) is a landmark. It was at Sutton Coldfield that John Wyatt, a native, invented a mechanical device in 1733 for spinning cotton. The parish church of Holy Trinity was built in the 14th century and contains the tomb of Bishop Vesey (d. 1555), a great benefactor of the town. The Vesey Memorial Gardens were laid out in 1938; his birthplace, Moor Hall, is a private house. Other old houses are New Hall at Walmley, the Moat House (Queen Anne) and the grove at Wishaw (14th century). Bishop Vesey's grammar school was founded in 1541 and the Roman Catholic seminary of Oscott College in 1785. Its first charter of incorporation (1528) gave the town the right to be described forever as the Royal Town of Sutton Coldfield and also gave 2,400 ac. (including 75 ac. of water) of Sutton Forest, now Sutton Park, to the town.

**SUTTON HOO SHIP BURIAL**, an early Anglo-Saxon king's grave containing a ship fully equipped for the afterlife (but no body), which came to light in 1939 with excavations at Sutton Hoo, an estate near Woodbridge, Suffolk, Eng. Richest Germanic burial found in Europe since the 17th century, it throws important light on the wealth and contacts of early Anglo-Saxon kings and is particularly valuable because burial of the dead in a ship is rare in England, although described in *Beowulf* (q.v.).

The ship's timbers had rotted away, but their impression in the sand and the rivets that remained showed it to be a mastless clinker-built rowboat more than 80 ft. long. The grave goods, laid out amidships, included a sword with a gold and garnet pommel, a gold-mounted shield, a visored helmet enriched with silver inlay, a mail coat, an iron-handled ax, three angons (throwing javelins), four spears, and a knife. Ceremonial objects, showing that the deceased was a king, were a wrought iron stand surmounted with a stag, which is explained as a unique Anglo-Saxon standard, and a great whetstone, 2 ft. long, carved with bearded faces.

The wealth of the obscure kingdom of East Anglia (q.v.) is shown by 41 items of solid gold, the fittings for a baldric, and

ceremonial regalia. These include a magnificent purse lid decorated with seven ornamental plaques, and a pair of curved and hinged epaulettes whose ornamentation of interlaced beasts and checker patterns is reminiscent of Hiberno-Saxon manuscript art. Small buckles and strap mounts, buttons, and pyramid studs for the sword knot are all lavishly decorated with garnets, and there is an impressive gold buckle weighing more than 14 oz.

Besides the gold cloisonné jewelry, probably made in a single English workshop, there was a quantity of imported silverware. One great silver dish bears the control stamp of the emperor Anastasius I (491–518) and is the only demonstrably Byzantine object so far found in England. In addition, there are a fluted bowl, a set of nine shallow bowls, a plain silver bowl, a ladle cup, and two spoons, probably christening presents, inscribed in Greek with the names Paul and Saul. A bronze bowl of Near Eastern manufacture and six small vessels made from gourds show wide East Anglian trading connections. The skill of the Celtic west is represented by three hanging bowls ornamented with enameled escutcheons, and inside one of these was found the remains of a small rectangular harp, the earliest postclassical instrument known. Domestic objects included bronze cauldrons, ironbound buckets, drinking horns, a pottery bottle, and textiles.

There was no body or cremated remains in the grave, and it is not certain whose cenotaph this was; its richness indicates a king and Merovingian coins found in the grave date the deposit 650–670. In that period three kings of East Anglia died: Anna (d. c. 653), Aethelhere (d. 654), and Aethelwald (d. 662–663). A pagan burial, albeit with such Christian elements as the spoons, is, however, surprising for any of the kings, especially the latest. Anna was a notable Christian; his body was buried at Blythburgh, Suffolk, but the memorial could have been put up to placate some of his heathen followers. Aethelhere, however, seems the most likely candidate; he died fighting at the River Winwaed for Penda, the pagan king of Mercia, and his body was probably not recovered from the battle where Bede says many perished by drowning.

The rite of ship burial and certain items in the grave are most closely paralleled in Sweden and postulate a hitherto unsuspected Swedish origin for the East Anglian royal dynasty.

The grave goods are now in the British Museum. **BIBLIOGRAPHY.**—R. L. S. **SUTTON-IN-ASHFIELD**, a market town and urban district in the Arkfield parliamentary division of Nottinghamshire, Eng., 12 mi. N.N.W. of Nottingham by road. Pop. (1961) 40,441. Area 16.4 sq.mi. The neighbourhood contains remains of Sherwood forest. Formerly the town relied solely on textiles but after the discovery of coal in the vicinity a variety of manufactures was introduced although its chief trade is still hosiery.

**SU TUNG-P'O** (regular name **SU SHIH**) (1036–1101) was one of China's greatest poets, painters and prose masters. He pioneered in the Sung school of Chinese painting. He excelled in dignified historical essays as well as in light, whimsical pieces. He was an authority in medicine who picked his own herbs, a great wine-bibber and maker of wines, a judge who sympathized with his prisoners, an inventor of such famous dishes as "Tung-p'o pork," an inkmaker, a renowned calligraphist whose every scribbled note was carefully preserved and whose family letters were inscribed in stone in his own lifetime. Wherever he was stationed as a magistrate, he dredged lakes, built canals, fought floods and constructed dams. He instituted hospitals and dispensaries, and was the first man to start the system of prison physicians because he could not stand the condition of the prisons. Alone, he fought the drowning of girl babies. He worked for famine relief and wrote successive letters to the empress dowager begging for forgiveness of tax to the poor. He forgave his friend who sent him to exile in Hainan Island, then almost outside the pale of civilization. All these

actions made him indubitably the most loved and admired scholar of his and later days.

Of the eight prose masters of the T'ang and Sung dynasties, the Su family accounted for three, Tung-p'o himself, his brother Su Tse-yu and his father, Su Hsün (1009-66). When he went to the capital to take his examinations, Ou-yang Hsiu, the acknowledged leader of the scholars, said when he read his writings, "I must give place to this young man." His reputation was established. Later the court attendants reported that whenever they saw the emperor's chopsticks stop moving in the midst of eating, they knew it was a memorandum by Su Tung-p'o he was reading. It was his misfortune that the emperor listened to Wang An-shih (q.v.), the social reformer, who banished all opposition to exile. Su Tung-p'o was first banished to Huangchow for four years (1080-84). With the emperor's death, during the regency of the empress dowager (1085-93), he was successively secretary to the emperor, governor of Chekiang, minister of civil service, of war, of education, and governor of Hopei. On the death of the empress dowager, he was banished to Huichow, in Kwangtung, and again to Hainan, whence he returned to China in 1101, one month before his death.

Tung-p'o's position and popularity came from a combination of literary brilliance and political integrity and his fearless championing of the people. His honesty with himself was the "bone" of his stature, while the charm of his personality, his wit, his gaiety and his literary accomplishments were the "skin and flesh" which gave to him the great charm which has endeared him to admirers throughout the generations.

See Lin Yutang, *The Gay Genius* (1947); *Selections from the Works of Su Tung-p'o*, trans. by C. D. LeGros Clark (1931); Burton Watson (trans.), *Su Tung-p'o: Selections from a Sung Dynasty Poet* (1965). (L. Y.)

**SUVA**, the capital, chief port and commercial centre, and largest town of the British colony of Fiji (q.v.), near the mouth of the Rewa River on the southeast coast of Viti Levu, or "great Fiji," the principal island. First occupied by European settlers in 1870, it was selected for the new capital in 1877 although the actual move from Levuka on the island of Ovalau was delayed until 1882. From the original site on the western side of the Suva Peninsula the town has spread to the north, west, and south, while reclamation has provided space for the expansion of warehouses, factories, wharves, and shipways. The rapidly increasing population reached 37,371 in 1956 and included 19,321 Indians, 9,758 Fijians, 3,394 Europeans, 2,094 part-Europeans and 1,647 Chinese. Administration is by an elected municipal council. Secondary schools and a teachers' training college serve all ethnic groups. The central medical school provides medical and dental courses for native students from Pacific islands as far distant as New Guinea. Besides a general hospital there are hospitals for mental and tuberculosis cases. Newspapers and periodicals are published in English, Hindustani, and Fijian. Industry includes cigarette and soap manufacture, copra-crushing, baking, and brewing. Electric power is generated locally. Slipway facilities are used by vessels from surrounding islands. (R. M. FR.)

**SUWOROV, ALEKSANDR VASILIEVICH**, COUNT (1730-1800), Russian military commander whose genius created a lasting tradition, was born in Moscow on Nov. 24 (new style; 13, old style), 1730, of a noble family, Swedish in origin. His father, V. I. Suvorov, had served under Peter the Great, reaching the rank of general. At the age of 12 Suvorov was enlisted in the Semenovski Life Guards Regiment, but until the age of 17 he remained at home, studying military subjects under his father's tutelage. He began serving in 1748 and spent about seven years as a guardsman before receiving his commission. He first saw action during the Seven Years' War (1756-63) and, having won rapid promotion to lieutenant colonel, took part in the Battle of Kunersdorf (1759) and in the advance on Berlin in the following year.

A dedicated soldier, Suvorov worked out new tactics and strategy, which proved effective against the Confederation of Bar and in the Russo-Turkish War of 1768-74, when he served under the outstanding Russian commander Count P. A. Rumyantsev and won promotion to general. In August 1774 the empress Catherine II, who was his friend, sent him to command a small detachment of

troops to support Count P. I. Panin in suppressing the peasant revolt led by Emelyan Pugachev (q.v.). Defeated before Suvorov could set out for Tsaritsyn, Pugachev was betrayed into Suvorov's hands in September 1774 and brought by him to Moscow.

During the Russo-Turkish War of 1787-91, Suvorov proved himself a brilliant commander. He successfully defended the shores of the Black Sea from Kherson to the Crimean Peninsula; and when on Oct. 12, 1787, the Turks tried to occupy Kinburn, in the Dnieper estuary, Suvorov, although twice wounded and far outnumbered, expelled them. His most resounding victories in this war, however, were in Moldavia: operating with an Austrian corps under Prince Josias of Saxe-Coburg, Suvorov used surprise tactics to defeat a greatly superior Turkish Army and took Focșani (Aug. 1, 1789); then, advancing with only 8,000 men to relieve an Austrian Army of 25,000, threatened by the Turkish Army, 115,000 strong, on the Rimnic River, he attacked and inflicted a major defeat (Sept. 22, 1789). He was created Count Rymnikski by Catherine II and a count of the *Reich* by her ally the Holy Roman emperor Joseph II in recognition of this heroic exploit. The capture of Izmail, in Bessarabia, on Dec. 22, 1790, crowned Suvorov's victories in this war, although, as with so many of his successes, it was marked by heavy losses of life, about 8,000 Russian and 10,000 Turkish troops perishing in the storming.

In August 1794 Suvorov commanded the army sent into Poland to suppress the insurrection led by Tadeusz Kosciuszko. The Poles had concentrated most of their forces at Praga, the eastern suburb of Warsaw, but Suvorov took it by storm on Nov. 4, giving it over to a massacre in which about 23,000 men and women perished. While Suvorov was a soldier of genius, he could also be, as one contemporary wrote, "a most barbarous warrior." Catherine II rewarded him with the baton of a field marshal.

Suvorov was next appointed in command of the armies in the south, where troops were assembling to march against the French Republic. At his headquarters at Tul'chin in the Ukraine (1796-97), he wrote his treatise *Nauka pobezhdad* ("The Science of Conquering"), setting out clearly and forcefully his principles of warfare and his views on the training of troops. This treatise became the manual of all Russian army commanders and has exercised a strong influence on Russian military thought.

On the death of Catherine II (November 1796) and the accession of Paul I, Suvorov fell from favour and went into exile on his estate in the Novgorod Province. When Russia joined the coalition against France (1798), he was recalled to command the army destined to operate against the French in Italy. In a series of rapid victories (April-August 1799), he expelled the French from Italy, except for a small force under Jean Moreau, gathered near Genoa. Suvorov was rewarded with the title of Prince Italiiski in recognition of these victories; and in October 1799 he was appointed generalissimo of the Russian forces. (See FRENCH REVOLUTIONARY WARS.)

At this juncture the allied command ordered Suvorov to march his army into Switzerland. He objected that conditions in the late autumn in the Alpine passes made such an operation excessively difficult. Both the Russian and the Austrian governments, however, overruled his objections. Suvorov hurriedly trained his troops in mountain warfare and made extensive plans to ensure his supplies, but difficulties mounted against him. His chief lieutenant, Gen. A. M. Rimski-Korsakov, was defeated by the French at Zürich. Then the French army, 80,000 strong, seized all mountain passes, thus surrounding Suvorov and his small army of about 22,000 men, but the wily old field marshal managed to extricate himself and to save his army. This Swiss expedition of 1799, in which Suvorov marched over the Alps, was his last and most brilliant exploit.

Suvorov, ill and exhausted, returned to Russia to find himself again in disgrace. The emperor Paul canceled the ceremonial welcome prepared some months earlier, and Suvorov was brought by night into St. Petersburg, the capital, to the house of a relative, where a fortnight later, on May 18 (N.S.; 6, O.S.), 1800, he died. There was a spontaneous demonstration of respect by the guards and people at his funeral, and within a year the emperor Alexander I erected a statue to his memory.

A small wiry man, Suvorov was incredibly brave, ruthless, and eccentric almost to the point of madness, but a military commander of genius. He was austere in habit, modest, but dry and sarcastic in speech, except to his troops who were as his children. He welded his regiments into indivisible units that he as their commander understood intimately, and he almost invariably led them into the attack himself. Swift in decision, Suvorov had an immediate intuitive appreciation of the military factors before him.

**BIBLIOGRAPHY.**—G. P. Meshcheryakov (ed.), *A. V. Suvorov: Dokumenty*, 4 vol. (1949–53); P. Longworth, *The Art of Victory; The Life and Achievements of Generalissimo Suvorov* (1965). (I. Gx.)

**SUWANNEE RIVER**, the river of Stephen Foster's song "Old Folks at Home," rises in the Okefenokee swamp in southeast Georgia. As the river moves southward through Florida it is augmented by the discharge of many springs, and also receives the Withlacoochee, Alapaha, and Santa Fe rivers. The channel is dredged 135 mi. (217 km.) inland from the Gulf to junction with the Withlacoochee; 250 mi. (402 km.) from its headwaters the Suwannee empties into the Gulf of Mexico, 22 mi. (35 km.) S of Cross City, Fla. All but 35 mi. (56 km.) of the river's course is in Florida. In north Florida the Suwannee flows over shoals and boulders between high limestone banks lined with second-growth cedar. In its middle course it moves quietly through wild hammock and forested areas; in dry weather it forms only a narrow channel in a river bed of limestone strata which have been eroded into numerous curious forms. The banks of the river are heavily wooded with cypress and live oaks. Exotic flowers including gardenia, orchids and ixia are abundant. Bass, perch, catfish, bream, and small game are plentiful.

In the 1780s the secluded bays and inlets of Suwannee Sound were rendezvous points for pirates. Tales of buried treasure still persist. The Suwannee was the boundary between the Timucua and Apalachee Indian tribes when northern Florida was explored. They called it the Guasaca Esqui, meaning "River of Reeds." The present name is thought to be a Negro corruption of San Juanee, meaning "little St. John." (M. C. P.)

**SUWAYDA', AS** (Es SUWEIDA; SOUEIDA; SWEIDA), a town and governorate of the Jebel Druze in the southern part of Syria. The town, which is the administrative centre of the governorate, is 55 mi. (89 km.) SSE of Damascus by road. Area (governorate) 2,143 sq.mi. (5,550 sq.km.); pop. (governorate, 1960) 99,519, (town, 1960) 18,154. The town, which stands on a hill on the site of a Roman settlement, is connected by road with Izra (Azra') and Damascus. The ancient name for the Jebel Druze was the Hauran. This area originally marked the boundary between Palestine and Syria. The northern part is known as El Lejja ("the refuge"), as robbers and rebels from the surrounding countries made it their hiding place. The volcanic soil is extremely fertile, and wheat, barley, vetches, and lentils are grown. Apples and grapes are marketed locally.

The town, whose ancient name was Soada or Dionysias, is said to have been founded by the Nabataeans but may date from an earlier period. The Nabataeans built a temple there to their god Dusares (later probably erroneously identified with Dionysus). The town came under Roman rule in the 1st century B.C., and Augustus handed it over to Herod the Great, in the possession of whose family it remained till A.D. 100. About 15 mi. (24 km.) SSW of As Suwayda' is the ancient site of Bozrah (q.v.).

(M. V. S.-W.)

**SUYUTI, AL-** (ABU-AL-FADEL ABD-AL-RAHMAN IBN ABI BAKR JALAL-AL-DIN AL-SUYUTI) (1445–1505), Arabic encyclopaedic author, whose works deal with almost every subject, the Islamic religious sciences predominating. He was the son of a judge of Alsiyut in Egypt. Tutored by a Sufi friend of his father's, he was precocious, being already a teacher in 1462. In 1486 he was appointed to a chair in the mosque of Baybars in Cairo. From 1501 until his death he worked in seclusion on the island of Rauda.

His works number several hundred, and, though many are short booklets, others are large-scale works. He was co-author of *Tafsir al-Jalalain*, a word-by-word commentary on the *Koran*, the first part of which was written by Jalal-al-Din al-Mahalli (1389–1459).

His *Itqan fi 'Ulum al-Koran* is a well-known work of koranic exegesis. Among his historical works is a history of the caliphs.

Suyuti was a compiler of genius rather than an original writer but it is precisely his ability to select and abridge which makes his books so useful. This faculty characterizes his best work, *Muzhir fi 'Ulum al-Lugha*, a guide to the Arabic science of lexicography. The work has been much used by European Arabists especially by E. W. Lane (q.v.) in the introduction to his lexicon.

See C. Brockelmann, *Geschichte der arabischen Literatur*, vol. 2, pp. 143–158 (1902), and supplement to vol. 2, pp. 178–198 (1938).

(J. A. Ho.)

**SUZDAL, PRINCES OF.** In Russian history the area between the Oka River and the Upper Volga was called the Suzda, land or *zemlya Suzdalskaya*. In the 10th and 11th centuries A.D. it was a remote corner of the Russian world, but during the 12th and 13th centuries it grew rapidly in political and economic importance, becoming a cradle of the Great Russian nationality. There the immigrants from the Russian south, which was devastated by nomadic invasions, found a quieter life and gradually merged with the scattered and peaceful indigenous Finnish tribes to form the bulk of the Russian peasantry.

The first important prince of the region was Andrew (q.v.; Russ. Andrei Yurievich) Bogolyubski, who ruled from 1157 to 1174. He moved his capital to Vladimir on the Klyazma River and successfully colonized and organized the area, becoming the most powerful among the contemporary Russian princes. His brother Vsevolod III (1176–1212) successfully continued Andrew's policies. Vsevolod's power and influence were felt by other Russian princes, as well as by the city-state of Novgorod the Great, which depended on Suzdalia for grain supply. But the political structure erected by Andrew and Vsevolod did not endure. The Suzda, princes regarded their territories as their private property and, accordingly, divided them by testaments among their sons. During the 13th and 14th centuries Suzdalia thus disintegrated gradually into several lesser principalities, which recognized the seniority of the grand prince of Vladimir only nominally. The Tatar conquest (in 1237–40) made the grand prince of Vladimir, as all other Russian princes, an obedient vassal of the Tatar khan.

Prince Konstantin Vasilevich (1332–55) succeeded in building the grand principality of Suzdal and Nizhni Novgorod, with the capital in Nizhni Novgorod (now Gorki) from 1350; and his son Dimitri even became grand prince of Vladimir in 1359–62. Soon, however, the throne of Vladimir returned to the grand prince of Moscow (q.v.); and in 1392 Prince Vasili I Dimitrievich of Moscow, empowered by the khan Tokhtamysh, seized the region of Nizhni Novgorod and annexed it.

(S. G. Pr.)

**SUZUKI, DAISSETZ TEITARŌ** (1870–1966), renowned Buddhist, the chief interpreter of Zen Buddhism to the West. Born in Kanazawa, Japan, on Oct. 18, 1870, he studied English literature during his college days in Tokyo and was greatly influenced by Ralph Waldo Emerson. He was also interested in Japanese literature and was a close friend of the writer Natsume Sōseki (q.v.). His philosophical interests covered classical Chinese philosophy, Buddhist philosophy (especially in the tradition of the Kego school), and Western philosophy. His friendship with the foremost modern Japanese philosopher, Nishida Kitarō (q.v.), lasted until Nishida's death. Suzuki was also an admirer of Emanuel Swedenborg (q.v.), whom he introduced into Japan by publishing his biography and translating four of his major works. Also, while Suzuki was a convinced follower of Zen Buddhism and trained under two great Zen masters, Imakita Kōsen and Shaku Sōyen, he had a profound appreciation of Shin Buddhism (see **BUDDHISM: Regional Variations in Buddhism: Japan**).

In 1893 Suzuki's Zen master, Shaku Sōyen, abbot of the Engaku-ji (temple) at Kamakura, represented Mahayana Buddhism at the World Parliament of Religions, held in Chicago. There he met Paul Carus (1852–1919), a philosopher and editor of the *Monist* and the *Open Court*. Carus was then interested in Chinese and Buddhist philosophies, and through Shaku Sōyen he secured Suzuki as his assistant. Suzuki thus went to LaSalle, Ill., where Carus lived, and there he remained until 1908, translating *Śāvaghosa's Discourse on the Awakening of Faith in the Mahayana* (1900).

T'ai-Shang Kan-ying P'ien: *Treatise of the Exalted One on Response and Retribution* (1906), and *Sermons of a Buddhist Abbot* (1906) and completing *Outlines of Mahayana Buddhism* (1907).

Upon his return to Japan in 1909, he taught English at the Peers' School and at Tokyo Imperial University. In 1911 he married Beatrice Lane (d. 1939), author of many works on Buddhism and Japanese art. In 1921 he accepted the chair of religious studies at Otani University (emeritus 1960), Kyoto, a Shin sectarian institution, where he also served for 20 years as editor of an English-language journal, *The Eastern Buddhist*. In 1934 he traveled through Korea, Manchuria, and China, and in 1936-37 the Japanese government sent him to lecture on Zen and Japanese culture in Europe and America. Some of his most famous works in English were written during his days in Kyoto—e.g., *Essays in Zen Buddhism*, 3 vol. (1927-34), *Studies in the Lankavatara Sutra* (1930), *An Index to the Lankavatara Sutra* (1933), *The Training of the Zen Buddhist Monk* (1934), *An Introduction to Zen Buddhism* (1934), the critical edition of *The Gandavyuha Sutra* (with H. Idzumi, 1934-36), *Manual of Zen Buddhism* (1936), *Buddhist Philosophy and Its Effects on the Life and Thought of the Japanese People* (1936), *Japanese Buddhism* (1938), and *Zen Buddhism and Its Influence on Japanese Culture* (1938).

In 1946 Suzuki established the Matsu-ga-oka ("Pine Hill") Library at Kamakura, and with a collaborator began publication of an English-language journal, *Cultural East*. He was made a member of the Japan Academy and was decorated by the Japanese government in 1949. In 1950, at the age of 80, Suzuki accepted the invitation of the Rockefeller Foundation to deliver lectures at several universities in North America. Except for intermittent visits to Europe and Japan, he was in the United States until 1958, mostly at Columbia University. The writings of his later years are interpretive rather than original: e.g., *The Zen Doctrine of No-Mind* (1949), *A Miscellany on the Shin Teaching of Buddhism* (1949), *Living by Zen* (1949), *Studies in Zen* (1955), *Mysticism: Christian and Buddhist* (1957), *Zen and Japanese Buddhism* (1958), *Zen and Japanese Culture* (1959), and (with Erich Fromm and Richard De Martino) *Zen Buddhism and Psychoanalysis* (1960).

After a tour of India in 1960, made at the invitation of the Indian government, he remained in Japan until his death on July 12, 1966. (S. Fu.; J. M. Ka.)

**SVALBARD** is part of the kingdom of Norway and comprises all islands in the Arctic Ocean between longitude 10° and 35° E and latitude 74° and 81° N. The main group of islands, known as Spitsbergen, consists of Vestspitsbergen, Nordaustlandet (North East Land), Edgeøya (Edge Island), Barentsøya (Barents Island), Prins Karls Forland (Prince Charles Foreland), and numerous smaller islands. Fringing the Spitsbergen group from north to south on the east are Kvitøya (White Island, or Gilles Land), Kong Karls Land (King Charles Land, or Wiche Islands), and Hopen (Hope Island). Further to the south is Bjørnøya (Bear Island). The total area of Svalbard is 23,958 sq.mi. (62,050 sq.km.); that of the Spitsbergen group is 23,641 sq.mi. (61,229 sq.km.), with Vestspitsbergen 15,075 sq.mi. (39,044 sq.km.). Other areas are: Nordaustlandet 5,610 sq.mi. (14,530 sq.km.); Edgeøya 1,942 sq.mi. (5,030 sq.km.); Barentsøya 514 sq.mi. (1,330 sq.km.); Prins Karls Forland 247 sq.mi. (640 sq.km.); Kong Karls Land 128 sq.mi. (331 sq.km.); Kvitøya 102 sq.mi. (265 sq.km.); Bjørnøya 69 sq.mi. (178 sq.km.); and Hopen 18 sq.mi. (47 sq.km.). There are no indigenous inhabitants. The population, consisting of miners and administrative staff living at the Norwegian and Soviet mining towns (see below), and some trappers and radio operators, changes seasonally; in the winter of 1965 it was about 1,000 Norwegians and 1,600 Russians and others. The administrative centre is Longyearbyen in Vestspitsbergen.

**Physical Features.**—Nearly 60% of Svalbard is covered by ice. The mountains along the west coast of Vestspitsbergen are rather wild with sharp ridges and peaks formed by folded and metamorphic pre-Devonian sediments. The eastern part of the island and Edgeøya and Barentsøya have plateau-formed mountains built up of nearly horizontal, younger sediments. In the northern part of Vestspitsbergen and Nordaustlandet there are more rounded

mountains built up partly of granites and gneisses. The highest peaks are in Ny Friesland, where Newtontoppen reaches 5,633 ft. (1,717 m.). In the southern part of Vestspitsbergen, Hornsundtind (4,695 ft. [1,431 m.]) is the highest mountain. Many large fjords penetrate the west and north coasts of Vestspitsbergen. The most important are Hornsund, Bellsund with Van Mijenfjorden and Van Keulenfjorden, Isfjorden with several branches, Kongsfjorden, and Krossfjorden on the west coast, and Woodfjorden and Wijdefjorden on the north coast. The west and north coasts of Nordaustlandet are also indented by fjords, but the east coast of this island is formed by the front of the inland ice. Many of the glaciers reach the sea, but in Vestspitsbergen there are also large ice-free valleys, such as Sassendalen, Adventdalen, Colesdalen, and Reindalen. In many parts of the coast there are extensive coastal plains, formed by the sea when its level was higher. Bjørnøya consists of an ice-free plain with many lakes, rising to Miseryfjellet (1,759 ft. [536 m.]) in the southeast.

**Structure and Geology.**—The principal features of the geology are known. Most formations from early Paleozoic, and perhaps Archean, to Recent, occur. The oldest rocks appear chiefly on the west and north, including Prins Karls Forland and Nordaustlandet. They are the Heclaheugen (Hecla Hoek) series of Pre-cambrian, Cambrian, and Ordovician dolomites, limestones, shales, and quartzites which form the Caledonian folds and overthrusts of the west. The folds can be traced as far east as the west of Nordaustlandet. Granite and gneiss were probably involved in the Caledonian foldings. The metamorphosed Hecla Hoek series and eruptives are in the northwest unconformably overlain by Devonian sandstones and shales. These are unconformably followed by Lower Carboniferous sandstones and shales with some coal, Middle Carboniferous or Upper Carboniferous limestones, Permian carboniferous cherts, and Permian sandstones and shales. Next come Triassic, Jurassic, and Cretaceous sandstones, and shales with some small coal seams. Unconformably, Tertiary sandstones and shales with several coal seams follow. Tertiary folding is obvious in the west against the Hecla Hoek beds. In the central part of southern Vestspitsbergen the Tertiary beds form a large syncline. Heavy faulting also occurred in Tertiary times. Intrusions of dolerites and basalt were probably of Cretaceous (Neocomian) date. An extinct volcano and several hot springs (28° C [82° F]) in Bock Bay are Quaternary. The strandflat is well developed up to 180 ft. (55 m.), and postglacial raised beaches are marked. Glacial and postglacial debris on low ground generally mask the solid rock, and loose scree forms fans on the lower slopes. Many Devonian and later deposits in Svalbard are extremely rich in fossils.

**Climate and Ice Conditions.**—The sea around Spitsbergen is shallow, and the ice readily accumulates round the shores. Pack ice prevents access to most shores except for a few months in the year. However, the warm North Atlantic drift sends a branch to the western shores of Spitsbergen, moderating its climate and leaving an open passage that permits vessels to approach the western coast during most months of the year. The fjords are frozen from October or November to May or June.

February and March temperature means are about -15° C (5° F) and July means are about 6° C (43° F). Extreme temperatures may rise to more than 21° C (70° F) in summer and fall below -40° C (-40° F) in winter. Records, though incomplete, indicate a marked rise in mean temperatures, especially for the winter months, during the first half of the 20th century. In September, autumn sets in. The Arctic night begins in October and lasts until the end of February. The annual precipitation at Grønfjorden (Green Harbour) is 11.6 in. (295 mm.); precipitation is often less in the interior. Winds are generally light except on the west coast. There is mist in the west.

**Vegetation.**—The only trees are the polar willow, which does not exceed two inches in height, and the rare dwarf birch (*Betula nana*). The vegetation consists mostly of lichens and mosses, variegated with the golden-yellow flowers of the ranunculus, the large-leaved scurvy grass, the cuckoo flower, many saxifrages, fox-tail grass, etc.; while on the driest spots yellow poppies, whitlow grasses, and mountain avens are found—poppies sometimes even

on the higher slopes, 2,500 ft. (760 m.) or more above the sea. In all, about 130 species of flowering plants have been collected. The distribution is suggestive: most species are found in Europe and 117 are circumpolar. In the ice-free valleys of Vestspitsbergen there is a comparatively rich vegetation of *Salix polaris*, grasses, moors with cotton grass, and Arctic flowers.

**Animal Life.**—According to the English explorer William Scoresby, no fewer than 57,590 whales were killed between 1669 and 1775. Reckless extermination of seals also took place. Walrus are now rarely seen in the waters west of Spitsbergen. There is a rich bird life. The fulmars, the glaucous gull or burgo-master, little auks, black guillemots, ivory gulls, and kittiwake gulls breed on the cliffs, while Arctic (Brünnich's) guillemots, puffins, pink-footed brant and barnacle geese, purple sandpipers, red-necked phalarope and other waders, and Arctic terns frequent the tundra and its pools. The commonest passerine bird is the snow bunting. The eider duck breeds on the islands, but its numbers have become noticeably reduced. These birds, however, are only summer visitors, the ptarmigan being the only species which stays permanently. In all, about 70 species have been recorded in Svalbard, of which about 30 breed there. Red char are the only fish found in the rivers and lakes. Land mammals are the polar bear, reindeer, and Arctic fox (both blue and white). There was heavy slaughter of reindeer before they became protected in 1925. The musk-ox, introduced from Greenland in 1929, is also protected, and has thrived, unlike the Arctic hare, another import from Greenland.

**History.**—**Exploration.**—It is probable that the Svalbard ("cold coast") discovered in 1194, according to Icelandic annals, and mentioned in the *Landnámabók* (see ICELANDIC LITERATURE) was Spitsbergen; modern knowledge of Svalbard, however, dates from its discovery by Willem Barents and Jacob van Heemskerck in June 1596. They first discovered Bjørnøya and later saw the northwest coast of Vestspitsbergen. After visits by Stephen Bennett in 1603, Henry Hudson in 1607, and Thomas Marmaduke in 1609, the Muscovy company sent an expedition in 1610, which resulted in the setting-up of the whaling industry in 1611, in which English and Dutch whalers took part. Later, French, Hanseatic, Danish, and Norwegian whalers also participated, and the king of Norway-Denmark laid claim to "this part of Greenland," as it was then considered. Quarrels among the whalers resulted in the division of the coast. The English had whaling rights south of latitude 79° N, whereas the Dutch erected their cookeries at Smeerenburg on Amsterdamøya, where more than 1,000 persons might be assembled in summer. The French were driven away from the coast in 1632 and had to boil their blubber on board their ships. After about 1640 the whales began to withdraw from the fjords and had to be caught off the coast. English whaling at Spitsbergen ceased in 1660, and Dutch whaling in about 1800, by which time the Greenland whale had been exterminated. English whalers were the first to winter in Spitsbergen, in 1630-31. Probably it was not until about 1715 that the Russians first visited Spitsbergen, wintering there to hunt walrus, seal, bear, fox, and reindeer. Many of them were sent out by the Solovetskiy monastery. Russian activity ceased in about 1850, but already at the end of the 18th century Norwegian sealers from Tromsø, Hammerfest, and other towns had been hunting in the Spitsbergen waters, and from 1822 they also wintered there to trap fur-bearing animals. This wintering was, however, not regular until the last years of the 19th century.

Many expeditions have made Spitsbergen their base for polar exploration, as C. J. Phipps in 1773, D. Buchan and John Franklin (*q.v.*) in 1818, D. C. Clavering and Edward Sabine (*q.v.*) in 1823, and William Edward Parry (*q.v.*), who in 1827 reached 82°45' N. In the same year the Norwegian geologist B. M. Keilhau visited the islands, and in 1837 Swedish exploration began with Sven Lovén's expedition. This was followed by many Swedish expeditions, including those of Otto Torell in 1858, Adolf Erik Norden-skiöld (*q.v.*) in 1864, 1868, and 1872-73, A. G. Nathorst, Gerard De Geer, and others, which were the foundation for later exploration. Other 19th-century exploration included the German expedition under K. Koldewey to the eastern part in 1868, that of Sir

Martin Conway (see CONWAY OF ALLINGTON, [WILLIAM] MARTIN CONWAY), who crossed Vestspitsbergen in 1896-97, and the Swedish-Russian expeditions of 1898-1902. In 1896 the Norwegians built a hotel on Hotellneset at Adventfjorden and started weekly trips by tourist steamers. In the first half of the 20th century Spitsbergen was visited by numerous scientific and exploring expeditions. In 1906 and 1907 the prince of Monaco sent a party, led by W. S. Bruce, who worked on Prins Karls Forland, and another party, led by Gunnar Isachsen, began mapping the north-western part of Vestspitsbergen. This led to Isachsen's expeditions of 1909-10, and later to Norwegian expeditions under the leadership of Adolf Hoel, A. Staxrud, and others. After 1948 this work was continued by the Norsk Polarinstitut, Oslo. From the early 1920s many British expeditions, associated particularly with the Oxford University Exploration Club, visited Spitsbergen, and some wintered there.

Spitsbergen has also been used as a base for polar flight. The first (fatal) attempt was in 1897, when the Swedish scientist S. A. Andrée and two companions set off by balloon from Danskøya; their remains were found on Kvitøya 33 years later. Roald Amundsen (*q.v.*) started from Ny-Alesund on his unsuccessful flight to the pole in 1925 and on his flight with Lincoln Ellsworth and Umberto Nobile (*qq.v.*) in the dirigible "Norge" across the pole in 1926. Richard E. Byrd (*q.v.*) also started from Ny-Alesund on his transpolar flight in 1926. Sir George Hubert Wilkins (*q.v.*) landed at the entrance of Isfjorden in April 1928 after his flight from Alaska, and, in May, Nobile started there in the dirigible "Italia," which met disaster north of Nordaustlandet.

**Political History.**—Despite diverse interests in, and claims to, the islands by British, Dutch, Norwegians, Swedes, Danes, Russians, and Americans, the question of sovereignty was long unsolved, and Spitsbergen was a *terra nullius*. Norway initiated a conference on the matter in Christiania (Oslo) in 1910, which was followed by others in 1912 and 1914, all without result. In 1919 F. H. H. Wedel Jarlsberg persuaded the Allied Supreme Council to grant Norway sovereignty over Spitsbergen, Bear Island, and all the lands lying between 74° and 81° N and between 10° and 35° E. This was put into effect by a treaty of Feb. 9, 1920, signed by Great Britain and the British dominions, the United States, France, Italy, Japan, the Netherlands, Denmark, Norway, and Sweden; the U.S.S.R. adhered later. Norway took formal possession on Aug. 14, 1925, and declared the region a part of the kingdom of Norway, under the old name of Svalbard.

The 1920 treaty forbade the erection of any naval base or fortress within Svalbard. Nevertheless, during World War II Spitsbergen was the scene of serious operations. In August-September 1941 an Allied force destroyed the radio stations, power stations, stocks of coal and oil, etc., and evacuated all Russians to the U.S.S.R., and Norwegians to Scotland. In the autumn the Germans erected a meteorological station in Longyearbyen. In May 1942 two vessels, "Isbjørn" and "Selis," were sent from England to prevent the mines from falling into German hands, but on reaching Grønfjorden they were destroyed by German aircraft. A small Norwegian force from England landed in July 1942 and occupied Barentsburg, Longyearbyen, and Sveagruva. After a German meteorological station had been destroyed in Krossfjorden in 1943, a large German force consisting of the "Tirpitz," the "Scharnhorst," and about ten destroyers entered Isfjorden on Sept. 8, 1943, and totally demolished the mining towns of Barentsburg, Grumantbyen, and Longyearbyen. In 1944 a German submarine set fire to Sveagruva. The Norwegian garrison was, however, maintained throughout the war. After the war all towns were rebuilt.

**Administration.**—Svalbard is administered by a governor (*sysselmann*), who is also district judge, chief of police, notary public, and revenue officer, and has his residence in Longyearbyen. An inspector of mines (*bergmester*) supervises mining activities. A 4% income tax is payable by Russians as well as by Norwegians. There are primary schools for children.

**The Economy.**—**Mining.**—Except for coal deposits, ore and mineral deposits are rather poor and scanty. Deposits of andrite with gypsum, marble, iron ore, asbestos, galena, zinc blende,

and pyrites have been found, but they have seemed too small or too poor to render mining profitable. Coal has been known since 1610 but it was not until the beginning of the 20th century that the deposits were thoroughly surveyed. From 1898 to 1920 many areas, most of them containing coal seams, were claimed by companies and persons from various countries. When Norway took over the sovereignty, a Danish commissioner was nominated to decide upon the ownership of these claims. He recognized a total area of 1,631 sq.mi. (4,223 sq.km.) as private property, of which by the early 1960s 6% belonged to the U.S.S.R. and the remainder to Norway. All other land is the property of the Norwegian government and may not be transferred into private possession, but the subjects of all signatory powers to the treaty of 1920 have equal rights to exploit mineral deposits. Coal mining on a commercial scale was started by John M. Longyear's Arctic Coal Company (Boston, Mass.) in Longyeardalen south of Adventfjorden in 1906 and by an English company on the north side of this fjord. The U.S. company exported 147,000 tons of coal between 1907 and 1915. In 1916 the property was sold to a Norwegian group that established Store Norske Spitsbergen Kulkompani A/S. A Swedish mine that was worked during 1917–25 at Sveagrava on the north side of Braganzavågen was sold to Store Norske in 1933. A Dutch company worked the mines at Barentsburg on the east side of Grønfjorden till 1926, but sold the property to the Soviet company Arktikugol in 1932. This company also took over the properties at Grumantbyen and Pyramiden. The only mines worked in the mid-1960s were Store Norske's in Adventdalen and Arktikugol's at Barentsburg and Pyramiden.

During the early 1960s coal exports from Norwegian mines exceeded 400,000 tons a year, from Soviet mines 200,000 tons. Shipment takes place mainly between the middle of May and the end of October.

Apart from mining, the only economic activity is trapping and hunting fox, polar bear, and seal, but since 1960 there has been increasing activity by U.S., Soviet, and Norwegian oil prospectors.

**Communications.**—Besides the coal steamers, a mail and passenger steamer makes eight trips during the summer from Tromsø to the Vestspitsbergen harbours. In summer Svalbard is also visited by large tourist steamers and many sealers. There are navigation lights and radio beacons in Bellsund-Van Mijenfjorden, Isfjorden, and Kongsfjorden, and Isfjord Radio at Kapp Linné provides a radar service. Svalbard Radio, situated in Longyearbyen, is linked with Norway; the other mining towns have local stations. See also ARCTIC, THE. (A. K. O.)

**SVEDBERG, THEODOR** (called "THE") (1884– ), Swedish chemist and Nobel Prize winner in 1926, developed physicochemical methods of studying colloids and macromolecules, particularly that of ultracentrifugation. He was born at Flerång, near Valbo, Swed., on Aug. 30, 1884. From 1904 he studied chemistry at Uppsala University, where he became professor of physical chemistry (1912–49), professor emeritus (1949), director of the Institute of Physical Chemistry (1931–49) and director of the Gustaf-Werner Institute of Nuclear Chemistry (1949).

The development of the ultracentrifuge made a profound and timely contribution to the study of large molecules. In this instrument the migration of large molecules in solution under the influence of a strong centrifugal force (up to 100,000 times gravity) can be observed and related to the molecular size and shape. By this means Svedberg demonstrated that the molecules of certain pure proteins are all of one size. Thus, the ultracentrifuge can sometimes, in the characterization of a new protein, show the presence of contaminating substances. In the field of high polymers the behaviour of long chain molecules, particularly cellulose, in the ultracentrifuge has contributed to the elucidation of their properties. For his studies in colloidal systems Svedberg was awarded the Nobel Prize. See also CENTRIFUGE.

See E. Farber, *Nobel Prize Winners in Chemistry* . . . (1963). (K. A. Sv.)

**SVENDBORG**, a port on the island of Fyn (Funen), Den., capital of Svendborg amt (county), lies on hilly ground at the narrows of Svendborg Sound, opposite the island of Tåsinge, 29 mi.

(47 km.) SSE of Odense by rail. Pop. (1960) 23,892. Noteworthy buildings are the 16th-century Anne Hvides house, now the county museum (nearby is the birthplace of the poet Johannes Jørgensen [1866–1956]), and the 13th-century churches of St. Nikolaj and Our Lady. To the east is Christiansminde, a wooded promenade bordering the sound. Svendborg is a yachting and tourist centre with ferry services to neighbouring islands. There are shipyards, an iron foundry, and light industries.

**SVENDBORG AMT** consists of the southeastern part of Fyn and the adjacent archipelago. Area 643 sq.mi. (1,665 sq.km.). Pop. (1960) 149,163. It abounds in magnificent old manor houses; e.g., Egeskov Castle, Brahetrolleborg, Hvidkilde, Valdemar Castle, and Tranekær. (O. C.)

**SVERDLOV, YAKOV MIKHAILOVICH** (1885–1919), Russian Communist leader and a key figure in the formative period of the Bolshevik Party's organization, was born in Nizhni-Novgorod (now Gorki) on June 3 (new style; May 22, old style), 1885, the son of an artisan named Nakhamkes. He joined the All-Russian Social-Democratic Labour Party in 1901 and was a "professional revolutionary" from 1902, always strictly following Lenin's policy. He took part in conducting Bolshevik activities in the Urals in the Revolution of 1905–07 and was later active in various parts of central Russia, being several times arrested and banished to Siberia. When in exile he was co-opted in January 1912 into the Central Committee of the party. From December 1912 to February 1913, having fled from Siberia, he was responsible for directing the work of the Bolshevik group in the Fourth Duma. Arrested again and deported to the Turukhan province in the polar circle, he remained there until the outbreak of the March Revolution in 1917. Returning to Petrograd he was sent to Yekaterinburg (now Sverdlovsk), becoming the principal Bolshevik leader in the Urals. He returned to Petrograd as a delegate to the April conference of the party, was reelected to its Central Committee and appointed its secretary, becoming the party's chief organizer. In November 1917 he was elected chairman of the All-Russian Central Executive Committee, thus becoming titular head of state. He took an active part in the preparation of the first Soviet constitution, supported Lenin against Trotski in the great debate over the peace treaty of Brest-Litovsk and, at the beginning of March 1919, was among the principal delegates to the first conference of the Communist (or Third) International. He died in Moscow on March 16, 1919. (L. B. Sc.)

**SVERDLOVSK**, an *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., was formed in 1934. Pop. (1959), 4,044,416. Area 75,174 sq.mi. (194,701 sq.km.). The *oblast* is roughly triangular, with its western side lying along the crest line of the Urals, which within the *oblast* reach a maximum height of 5,148 ft. (1,569 m.) in Gora Konzhakovski Kamen. The *oblast* includes the eastern slope of the Urals and stretches out to the flat West Siberian plain (Zapadno-Sibirskaya Nizmennost). Its southwestern corner extends across to the western flank of the Urals in the upper Ufa basin. The main rivers draining eastward are the Tavda, with its headstreams Lozva and Sosva, and the Tura, with its tributaries Nitsa and Pyshma. The climate is sharply continental, January average temperatures ranging from  $-16^{\circ}\text{C}$  ( $3^{\circ}\text{F}$ ) in the southwest to  $-20^{\circ}\text{C}$  ( $-4^{\circ}\text{F}$ ) in the north, and July averages about  $16^{\circ}\text{--}17^{\circ}\text{C}$  ( $61^{\circ}\text{--}63^{\circ}\text{F}$ ). Rainfall is about 16 in. (41 cm.) a year on the lowland, rising to 24 in. (61 cm.) on the Urals. Almost the entire *oblast* is covered in taiga forest of pine, stone pine, birch and larch, with spruce, fir and oak appearing in the southwest. Only the highest summits of the Urals are bare; in the extreme south the *oblast* enters the forest-steppe zone, with alternating birch groves and grass steppe.

Of the 1959 population, more than three-quarters were urban dwellers, a reflection of the *oblast's* role as part of the Urals industrial region. The largest of the 39 towns and 88 urban districts are the administrative centre Sverdlovsk (778,602), Kamensk-Uralski (141,019), Serov (97,882), Asbest (60,053), Pervouralsk (91,034), Krasnoturinsk (qq.v.; 61,990), Nizhni Tagil (338,501), and Revda (54,870).

Like all the Urals region, the *oblast* is exceptionally rich in the range and quantities of minerals. Iron ore is mined in the Serov-

Ivdel area, at Nizhni Tagil and at Kushva. Manganese occurs at Ivdel; chromium at Kluchevsk; cobalt, nickel, tungsten and vanadium near Sverdlovsk; beryllium near Asbest. Copper is mined at several places including Alapayevsk, Degtyarsk, Krasnouralsk and Kirovgrad. Asbest has the largest deposits of asbestos in the U.S.S.R. Bauxite is found at Kamensk-Uralski and Serov, and Polevskoi is a major producer of artificial cryolite. Platinum and gold are widespread, and zinc and sulfur deposits are worked. Coal and lignite are of inferior quality. Based on these minerals a large metallurgical industry developed in the 1930s and received further impetus during World War II. Nizhni Tagil has one of the largest iron and steel plants of the Soviet Union and smaller works are located at Serov, Kushva, Pervouralsk, Revda and Severski. Sverdlovsk and Nizhni Tagil are centres of large-scale heavy engineering. Nonferrous metals are processed in Krasnoturinsk, Krasnouralsk, Kirovgrad, Kamensk-Uralski and Revda (copper). There is a thriving chemical industry producing industrial chemicals, plastics, fertilizers and medical preparations. Timber working is widespread and well developed. The chief lack of the *oblast* is fuel. Coking coal is brought from Karaganda (Kazakh S.S.R.) and the Kuzbass (Kuznetsk basin) and natural gas is piped from Berezhovo in the northern Urals. Agriculture is relatively unimportant and largely confined to the southeast (around Irbit), where grains and potatoes are grown. Market gardening is important around the towns.

All the main centres are connected by a rail network which is linked to the Trans-Siberian railroad. (R. A. F.)

**SVERDLOVSK** (formerly YEKATERINBURG), a town and administrative centre of the *oblast* of the same name in the Russian Soviet Federated Socialist Republic, U.S.S.R., lies on the eastern slope of the Ural mountains on both banks of the Iset river, a tributary of the Tobol, 850 mi. (1,368 km.) E. of Moscow. Pop. (1959) 778,602. The town has two 18th-century cathedrals and is the leading cultural and educational centre of the Urals region. It has a musical *conservatoire* and opera and dramatic theatres; a polytechnic; and institutes of mining, forestry, agriculture, medicine, law and teaching. It is also the seat of the Urals A. M. Gorki State university (founded 1920) and of the Urals branch of the U.S.S.R. Academy of Sciences.

Sverdlovsk is an important railway junction. Seven lines radiate from it to all parts of the Urals and the rest of the Soviet Union, including Moscow, Leningrad and Omsk. Its chief importance lies in heavy engineering, for which it is one of the largest centres of the U.S.S.R. Among its wide range of products are machines for the metallurgical and chemical industries; mining and oil drilling equipment; turbines, diesels, ball bearings, electrical equipment, cables, precision instruments, refrigerators and bicycles. The chemical and rubber industries (plastics, tires) are well developed. Steel manufacture, utilizing pig iron from other centres and scrap, is still maintained but is less important than in other Ural centres. Light industrial products include footwear and other leather goods, clothing, tobacco and food-stuffs. A traditional craft is the cutting of gems.

Sverdlovsk has its origin in the establishment there in 1721 of the Verkhne-Issetski (Upper Iset) ironworks and fortress by V. N. Tatischev, historian, traveler and government functionary; and the settlement became the administrative centre for all the ironworks of the Urals. It was named Yekaterinburg in 1723 for Catherine I, wife of Peter I the Great. Other ironworks developed in the vicinity, and its industrial and administrative importance was increased from 1783 when the Great Siberian highway was built through it. The first railway arrived from Perm in 1878 and several other lines were laid from it during the next fifty years. After the Revolution Yekaterinburg was the last place of imprisonment of the tsar Nicholas II and his family, who were shot there on the night of July 29–30 (N.S.; July 16–17 O.S.), 1918, to prevent their escape to Kolchak's White Russian army which was advancing toward the town. Yekaterinburg fell to the White troops a week later and was recaptured by the Red army in July 1919. It was renamed Sverdlovsk for the Bolshevik Yakov Sverdlov in 1924. Evacuation of industry to the Urals during World War II gave further impetus to expansion. (R. A. F.)

**SVERDRUP, JOHAN** (1816–1892), Norwegian statesman, first leader of the Venstre (the Left) Party, and prime minister from 1884 to 1889, was born at Jarlsberg on July 30, 1816. His father, Jacob Sverdrup, founded the first school of agriculture in Norway. Educated as a lawyer, Sverdrup entered the *storting* (legislative assembly) in 1851 and soon became leader of the opposition group of city liberals. He was president of the *odelsting* (the lower division of the legislative assembly) from 1862 to 1869 and president of the *storting* from 1871 to 1884. Through an alliance with Søren Jaabaek, leader of the Peasant Party, Sverdrup created (1869) a unified liberal and national opposition, the Left. He was its unquestioned leader during the long fight (1872–84) against the government over the admission of ministers to the *storting* (see NORWAY: History).

The victory of the *storting* in 1884 brought Sverdrup the office of prime minister in Norway's first Left ministry. Many reforms for which he had worked since 1851 were now authorized, notably an extension of the franchise (1884) and the introduction of trial by jury and of universal conscription (1887). Soon, however, Sverdrup found himself at issue with the radical majority of his party on questions of religious toleration and church reform and on the handling of the problems of the Swedish-Norwegian union. A controversial church reform bill, introduced by Sverdrup's nephew Jakob Sverdrup, minister of ecclesiastical affairs, was defeated in 1887. In the elections of 1888 Sverdrup lost his absolute majority, and when a motion of no confidence in his government was proposed in the *storting* in June 1889, he resigned before it could be debated. He died at Christiania (now Oslo) on Feb. 17, 1892.

See H. Koht, *Johan Sverdrup*, 3 vol. (1918–25). (D. Ma.)

**SVERRE** (d. 1202), king of Norway from 1177 to 1202, was one of the most remarkable kings and controversial figures of medieval Norway. He was born in the Faeroe Islands, supposedly in 1149, and was ordained as a priest at an unusually early age by Hrói, bishop of the Faeroes. His mother was a Norwegian, Gunnhild, married to a Faeroe man, Unas the Combmaker. But, according to Sverre's own story, his mother had confessed to him that she had begotten him, not with Unas, but with Sigurd II Munnr (d. 1155), a former king of Norway. There are good reasons to doubt the truth of this story, but if Sverre was, in fact, the illegitimate son of Sigurd, he had a valid claim to the throne of Norway.

In 1174 Sverre left the Faeroes for Norway. At this time Norway was ruled by Erling the Crooked and his young son Magnus IV, whose claims to the throne were somewhat doubtful. Their rivals, called the Birchlegs, were now in severe straits, and their pretender, Eystein, was killed after a crushing defeat in January 1177.

The remnants of the Birchlegs gathered round Sverre, imploring him to lead them. Within a few months, Sverre had seized Trondheim, where he was proclaimed king. During the next years his fortunes varied, but he showed military skill, as well as the power of leadership, and in 1179 he won a great victory in which Erling was killed and his son Magnus put to flight. In 1184 Sverre met Magnus at Fimreite, in the Sognefjord, and Magnus fell in the ensuing battle, leaving Sverre virtual ruler.

Sverre's relations with the church are particularly interesting, and it is plain that he represented the national, as opposed to the universal, church movement. In 1180 Eystein Erlendsson, archbishop of Trondheim, who had consistently sided with King Magnus, fled to England, where he remained three years. He then returned to Norway, where he died in 1188. Eystein was succeeded as archbishop by Erik Ivarsson, with whom Sverre's differences were graver, culminating in the archbishop's refusal to crown Sverre and his flight to Denmark in 1190. In 1194 Sverre was crowned by bishops who had remained in Norway, but later Pope Innocent III intervened on the side of the exiled archbishop. He solemnly excommunicated the bishops who had assisted at Sverre's coronation and in a series of bulls anathematized Sverre as an apostate, excommunicate enemy of God and the saints and condemned all who associated with him. Norway was, in fact, under interdict.

In his latter years, Sverre contended successfully against new claimants to the throne. He died in his bed, as few kings of Norway had done, at Bergen, on March 9, 1202.

The life of Sverre (*Sverris Saga*) was written in part by the Icelandic abbot Karl Jónsson, under the direction of the king himself. It was later completed by other Icelandic scholars. Sverre is depicted as a consummate orator, and as something of a mystic, with an implicit faith in his own destiny and especially in dream symbolism.

See G. M. Gathorne-Hardy, *A Royal Impostor* (1956); F. Paasche, *Kong Sverre* (1920). (G. T.-P.)

**SVINHUFVUD, PEHR EVIND** (1861–1944), Finnish statesman, first head of state of independent Finland in 1918 and president of the republic in 1931–37, was born at Sääksmäki on Dec. 15, 1861, a member of a noble family. Having completed his studies in law (1886), he entered the Finnish Diet in 1894 as representative of his family in the House of Knights and soon became known as a steadfast Constitutionalist (see FINLAND: History). During the great strike (1905) he coordinated the activities of the Constitutionalist and the Social Democrats. After the reform of the Diet he was its speaker from 1907 until the end of 1912. He was exiled to Siberia in 1914, returning after the Russian Revolution of March 1917. Uncompromisingly anti-Russian, he was elected prime minister by the votes of the bourgeois parties of Finland on Nov. 27. When the Red Guard forces seized power in southern Finland, he managed to escape to Ostrobothnia, whence he conducted the government during the war of independence. Elected regent of Finland on May 18, 1918, he was in favour of having a German prince as king; and his policy led to his resignation, on Dec. 12, after Germany's collapse at the end of World War I. When the parties were regrouped, Svinhufvud joined the national coalition.

Prime minister from July 5, 1930, to Feb. 16, 1931, and president from March 2, 1931, to Feb. 28, 1937, Svinhufvud saw to it that the demand of the right-wing Lapua movement for the banning of the Communist Party was carried through but used his presidential authority to prevent the movement from overthrowing democratic institutions. He died at Luumäki, on Feb. 29, 1944.

See E. Rääkkönen, *Svinhufvud: the Builder of Finland* (1938); E. W. Juvä, P. E. *Svinhufvud*, 2 vol. (1957–61). (E. K. I. J.)

**SVISHTOV**, a town in Turnovo Okrug (administrative district), Bulg., capital of Svishtov Obshtina (secondary administrative district), stands on the right bank of the Danube, 40 mi. (64 km.) WSW of Ruse. Pop. (1963 est.) 22,111. Ranking third after Ruse and Lom among Bulgaria's Danubian ports, it is the commercial centre of a fertile wine-growing region. It has economics and business colleges, and the first of the Bulgarian library clubs, which fostered popular education, was founded there in 1856. It is the birthplace of the writer Aleko Konstantinov (1863–97) and of the artist Nikolai Pavlovich (1835–94). A branch railway line from Levski connects Svishtov with the main Sofia-Varna line. Flour, canned goods, and vibrated concrete are produced, and exports include ore concentrates, foodstuffs, and wine. Svishtov arose as the Roman fortress of Novae. In feudal times it was moved farther eastward and was called Stuklen. Later it was restored to the original site. (AN. BE.)

**SVYATOSLAV I** (SVYATOSLAV IGOREVICH, d. 972), grand prince of Kiev from 945 and a hero of early Russian history, was the son of Igor and Olga (qq.v.). After coming of age, he dedicated all his efforts to bold military expeditions, leaving his mother, Olga, in Kiev to take care of the internal affairs of the state until her death in 969. The Russian chronicle describes the last heathen Russian prince, who "stepping light as a leopard . . . carried with him neither wagons nor kettles . . . nor did he have a tent. . . . He sent messengers to the other lands announcing his intention to attack them." Between 963 and 965 he defeated the Khazars on the lower Don and the Ossetians and Circassians in the northern Caucasus and stormed the capital of the Volga Bulgars. When the Byzantine government, engaged in a war against the Balkan Bulgars, asked Svyatoslav for help, he invaded Danubian Bulgaria in 967 and defeated the Bulgars. He then refused to cede his conquests to the Byzantines, declaring his intention of establishing his

capital in Pereyaslavets (Pereyaslav-Khmelnitski) on the Danube and founding a Russo-Bulgarian empire. The Byzantine emperor John I Tzimiskes, having gathered overwhelming forces, defeated Svyatoslav's relatively small army and forced him to abandon any claims to Balkan territory (971). In the spring of 972, while Svyatoslav was returning to Russia with a small retinue, he was ambushed by the Pechenegs near the cataracts of the Dnieper and killed.

See *The Russian Primary Chronicle*, Eng. trans. (1953); G. V. Vernadsky, *Kievan Russia* (1948). (S. G. Pu.)

**SWABIA** (German SCHWABEN), the historical name for the southwesternmost part of the old German kingdom or *Reich*, comprising, in 20th-century terms, not only the southern part of the German Federal Republic's *Land* Baden-Württemberg, together with the southwestern part of the *Land* Bavaria, but also eastern Switzerland and Alsace (qq.v.). The present article covers (1) the Duchy of Swabia; (2) the Swabian leagues of the 14th–16th centuries; and (3) the Swabian Circle of the *Reich*.

**The Alamanni and the Duchy.**—The name Swabia is derived from that of the Suebi (q.v.), a Germanic people. With the Alamanni (q.v.), some Suebi in the 3rd century A.D. moved into the Roman territory between the upper Rhine and the upper Danube and along the Neckar River. Further expansion, westward over the Rhine, southward beyond Lake Constance, and eastward to the Lech River, led to the consolidation of a territory known at first as Alamannia. From the 11th century this name was superseded by Swabia.

The Alamanni were subdued by the Frankish king Clovis between 496 and 506, and Frankish supremacy over their dukes was reinforced by Charles Martel in 730. The people lived under the *Lex Alamannorum*, a code of law dating from the 6th–8th centuries (edited in the *Monumenta Germaniae Historica*, 1888). Promulgated by their Frankish overlords, this law nevertheless shows deep respect for the traditions of the Alamanni—whereas the later *Schwabenspiegel* (drafted in Augsburg in 1274–75; edited by H. Planitz and A. Benna, 1956) has no specifically Swabian characteristics in its approach to legal matters. The Alamanni long remained pagan, but in the 7th century the process of converting them to Christianity started; it was achieved mainly by Irish missionaries. The bishoprics of Basel, of Constance, and of Augsburg and the abbeys of St. Gall and of Reichenau began to play an important role.

Swabia emerged, together with Saxony, Franconia, Bavaria, and Lotharinga (Lorraine), as one of the five great duchies of the East Frankish or German Kingdom (see GERMANY: History). At the turn of the 9th–10th century the counts of Raetia temporarily obtained the Swabian dukedom, but there followed a rapid succession of dukes belonging to other families. Rudolf of Rheinfelden, duke of Swabia from 1057, was set up as German king in opposition to King Henry IV in 1077 (see RUDOLF), but in 1079 Henry enfeoffed his own son-in-law, Frederick of Hohenstaufen, as duke of Swabia. The latter's grandson became German king, as Frederick I, in 1152, and the duchy of Swabia remained in the hands of members of the Hohenstaufen dynasty till the extinction of its legitimate male line in 1268. Thereafter local nobles, in particular the counts of Württemberg (q.v.), encroached on the royal and ducal lands. The German king Rudolf I, of the Habsburg dynasty, was able to consolidate what was left of Swabia as a duchy for his son Rudolf II of Austria; but the latter died in 1290, and his posthumous son, John, was only nominally duke of Swabia. With his death (1313) the title fell out of use.

**The Swabian Leagues.**—From the emperor's court of justice at Rottweil attempts were made to assert the authority of the *Reich* over the numerous lordships of the Swabian nobility. In 1331 a league was formed by 22 Swabian free towns or Imperial cities (q.v.), including Ulm, Augsburg, Reutlingen, and Heilbronn, to support the emperor Louis IV in return for his undertaking not to mortgage any of them to a vassal. Count Ulrich III of Württemberg (d. 1344) was induced to join this league in 1340; but during the emperor Charles IV's reign the Swabian knights in 1366 formed a league of their own, the Schlegelbund (so named from the hammer or mallet, Ger. *Schlegel*, in its insignia), in opposition

to the towns and to the greater territorial princes alike. Civil war ensued; Charles tried to set up a league under his own control for the maintenance of the public peace; and finally Ulrich's son and successor, Eberhard II of Württemberg (d. 1392), with the help of the Schleglerbund, defeated the towns' league in 1372.

A new Swabian towns' league, led by Ulm and comprising 14 Imperial cities, was formed on July 4, 1376. Its aim was to protect its members' status against any threat of mortgaging, to safeguard their commercial interests, to resist excessive taxation, and to preserve the public peace. After its victory over Count Eberhard's son Ulrich at Reutlingen on May 14, 1377, it spread its influence into Bavaria, Franconia, and the middle Rhineland, as well as the outlying Swiss and Alsatian areas of the old Swabia; after its declaration of war against the dukes of Bavaria, however, the new league was also defeated by Eberhard II of Württemberg at Döfingen (August 1388).

The Schleglerbund was overthrown when Eberhard III of Württemberg captured its stronghold of Heimsheim on Sept. 24, 1395.

The Swabian League that was founded at Esslingen on Feb. 14, 1488, was a more comprehensive organization than the 14th-century leagues. Promoted by the emperor Frederick III, it comprised not only 22 Imperial cities but also the Swabian knights' League of St. George's Shield and the local prelates. Sigismund of Tirol and Eberhard V of Württemberg were promptly brought into it; the Palatinate, Mainz, Trier, and Baden soon acceded; and Hesse and Bavaria, as well as Ansbach and Bayreuth in Franconia, eventually became members.

A federal council, with princes, towns, and knights represented in three "colleges," was constituted for the league; and provision was made for an army of 13,000 men to maintain order, under an appointed captain. The league helped rescue Frederick's son, the future emperor Maximilian I, from captivity in the Netherlands in 1488, forced Duke Albert of Bavaria to renounce Regensburg in 1492, and was the mainstay of Habsburg authority in southwestern Germany throughout Maximilian's reign. When Duke Ulrich I of Württemberg seized Reutlingen (1519), the Swabian League expelled him from his duchy, which it then sold to the emperor Charles V (1520). It cooperated in the overthrow of Franz von Sickingen (*q.v.*) in 1523 and in the suppression of the peasants' rebellion of 1524-25. The Reformation, however, led to the expiry of the Swabian League (which had been several times formally renewed) in February 1534. Attempts to revive it, by the Bavarian chancellor Johann Eck in 1535 and by Charles V in 1547, came to nothing.

**The Swabian Circle.**—The name of Swabia was perpetuated in that of the Swabian Circle of the Empire (*Schwäbischer Reichskreis*), one of the zones into which Germany was divided, from the 16th century onward, for purposes of Imperial administration. First organized in 1500, this circle was finally established in 1555 and lasted till the dissolution of the Holy Roman Empire in 1806. It was bounded west by the Upper Rhenish Circle, north by the Electoral Rhenish and by the Franconian, east by the Bavarian, and southeast by the Austrian, which had numerous exclaves within it. There was also a Swabian Towns' Bench (*Schwäbische Städtebank*) in the old *Reichstag* or Diet of the Empire.

**SWAHILI LANGUAGE.** Swahili (Kiswahili) is a Bantu language spoken primarily on the east coast and islands of Africa between Lamu Island, Kenya, in the north and the mouth of the Ruvuma River (southern border of Tanzania) in the south. It is spoken sporadically as far north as Mogadishu, Somali Republic, and there appear to be Swahili-speaking enclaves in French Somaliland; it has also been heard as far south as Mozambique. A form of Swahili is also spoken on the west coast of Madagascar (Malagasy Republic). People who speak Swahili as their sole mother tongue are usually referred to as Waswahili, but this name

refers to their language only and does not denote any one tribal unit. At the coast there is considerable Arab influence, both racial and cultural, and Islam is the dominant religion. There are about 15 main Swahili dialects, as well as several pidgin forms in use.

Swahili as a lingua franca is current in: (1) Tanzania, where it is the language of administration and primary education; (2) Kenya, where it is also the main language for these purposes though alternative languages have been recognized in certain parts of the country; (3) Uganda, where it is in competition with local languages; (4) Republic of the (former Belgian) Congo, where a form of Swahili (sometimes called Kingwana) is one of the four permitted languages of administration and where its use in education depends largely on mission society policy, although there are a few communities where Swahili appears to be the mother tongue. Swahili is regarded, with Nyika (including Giryama, as a language group closely related to the Taita language group.

Although modern Swahili contains an enormous vocabulary of Arabic borrowings (as well as borrowings from Persian, Hindi, Portuguese and English), in its grammatical behaviour it is characteristically Bantu; *i.e.*, (1) it has a large vocabulary of word roots traceable to a common Bantu stock; (2) its nouns are divided into classes, distinguished by typical prefixes, for the most part groupable in pairs denoting singular and plural; *e.g.*, *m-tu*, pl. *wa-tu* ("person"), *ki-tu*, pl. *vi-tu* ("thing"), etc.; (3) verbs, adjectives, demonstrative and possessive forms are brought into agreement with nouns by means of prefixes; *e.g.*, *wa-tu wa-etu wa-le wa-kubwa wa-mekuja* ("those big people of ours have come"); (4) verb stems may be extended by means of suffixes, each with a particular nuance of meaning; *e.g.*, *funga* ("shut"), *fungwa* ("be shut"), *fungika* ("become shut"), *fungio* ("shut for"), *fungisha* ("cause to shut"), *fungua* ("open"), etc.

**Origin and History.**—The name Swahili is derived from the Arabic *sawāhili* ("coastal"). Contact between Arabia and the east coast of Africa was made as early as the 1st century A.D. when, according to the *Periplus of the Erythraean Sea*, the people of Muza (in southern Arabia) "sent thither many large ships, using Arab captains and agents, who are familiar with the natives and intermarry with them." But the earliest known settlement at Pate is said to have been founded in A.D. 689. During the next 600 years other cities such as Lamu, Malindi, Mombasa and Kilwa were founded and reached a high level of civilization, until eclipsed by the Portuguese conquests in the early 16th century. After the Arabs had returned and ousted the Portuguese in the early 18th century and transferred their court from Oman to Zanzibar in 1832, Swahili came into its own, enhanced by the intermarriage of the Arab overlords with the coastal people.

During the early 19th century the spread of Swahili inland received a great impetus through its being the language of the Arab ivory and slave caravans, which penetrated as far north as Uganda and as far west as the upper reaches of the Congo (Zaire) river. It was later adopted by Europeans. It has been challenged by local vernaculars in certain regions and there has also been a tendency among some Africans to prefer the metropolitan language as lingua franca. Swahili is the officially recognized national language of Tanzania.

**Literature.**—The earliest literature in Swahili was written in the Arabic script and a certain amount still exists in manuscript. Some has been published. In the latter half of the 19th century the roman alphabet was successfully applied to Swahili by missionaries and the first complete Bible was produced by 1891 in the Mvita (Mombasa) dialect. For several years there was strong rivalry between this dialect and that of Zanzibar (Unguja), until the latter obtained official recognition as "standard" in the 1920s. Afterward the written language progressed apace, under the encouragement of the Interterritorial Language (Swahili) committee—later the East African Swahili committee—and the years after World War II saw an enormous development. Besides further Bible translations (including the "Union Version" of 1950) and a spate of government-inspired textbooks for schools and adult literacy campaigns, there are about 60 Swahili newspapers and broadsheets in East Africa and a dozen in the Congo area. Indige-

nous authors have gradually come to the fore, among whom Shaaban Robert is outstanding.

**SWALLOW**, among the best-known of birds, an accomplished flier that captures its insect food on the wing, with much graceful twisting and turning. About 74 species of small to medium-sized songbirds constitute the almost cosmopolitan family Hirundinidae, but three species are particularly well known: *Hirundo rustica*, the common, or barn, swallow; *Riparia riparia*, the bank swallow; and *Petrochelidon pyrrhonota*, the cliff swallow. Swallows have long been celebrated in both literature and song as the epitome of diligence and hopefulness; in Christian symbolism they represent suppliant prayers, perhaps because swallows always seem to be hungry.

Contrary to popular legend, the cliff swallows that have built their mud nests in the ruins of the Mission San Juan Capistrano in California since Spanish colonial times do not leave on the same day each autumn (Oct. 23, St. John's Day) nor do they return on the same day each spring (March 19, St. Joseph's Day); food supply and weather greatly influence their migrations.

Swallows share superficial features with the unrelated swifts; these adaptations to a predominantly aerial life include long, pointed wings, small feet suited more for perching than for walking, short broad bill, and wide gape. Most swallows have notched tails, but the barn swallow's is deeply forked and the cliff swallow's is squared. Their colours are not gaudy, but many species have rufous or glistening white and iridescent deep-blue or green in the plumage. The species breeding far north and south are strongly migratory, and some make long journeys across the Equator to reach their winter quarters.

Swallows like company. They gather to feed in favourite spots; great numbers may assemble in the late afternoon to roost together during the night, and many species nest in colonies. Certain species come commonly about human habitations and nest on buildings or in nest boxes prepared for them. Though hardly songsters, their twitterings and chirping notes are pleasant, and this, plus their familiar habits and their returning to temperate climates with the spring, has given them a friendly place in people's minds and in literature. Their nesting is various: in a hole in a tree or bank, in a burrow dug by themselves in an earthen bank, a saucer-shaped structure on a ledge of rock or a building, or a retort-shaped structure of mud pellets stuck to the side of a cliff, cave, or building. There may be up to six eggs, pure white or spotted.

(A. L. Rd.; X.)

**SWAMMERDAM, JAN** (1637-1680), Dutch naturalist and zoologist, first described the red blood corpuscles and made one of the finest collections of microscopic observations ever published. He was born on Feb. 12, 1637, at Amsterdam. His father was an apothecary and naturalist who had a museum of curiosities, and Swammerdam started his career by helping with the museum. He went to Leiden University in 1661, graduating in medicine in 1667. Neglecting his practice, he became a pioneer of microscopy. He made a comparative study of insect life histories, which he classified according to the type of metamorphosis. He went into minute details of the internal anatomy of the mayfly and the bee; observed the cleavage of the frog's egg and studied the anatomy of tadpole and adult; described the ovarian follicles of mammals in the same year as Regnier de Graaf (q.v.; 1672); and evolved improved techniques of injection, which aided his study of human anatomy. Swammerdam discovered the valves of the lymphatic

vessels. His description of the red blood cells was made in 1658. By a well-devised experiment he showed that the muscles alter in shape but not in size during contraction; this contradicted the current theory that a material fluid passed down the nerves to cause movement. He was the first to draw the sporangia of a fern. Deeply religious and somewhat unstable, he became for a time, after a quarrel with his father, a disciple of Antoinette Bouignon (q.v.).

Swammerdam died in Amsterdam on Feb. 15, 1680, after a period of deep spiritual and bodily misery.

His books, some of them magnificently illustrated, were: *Tractatus physico-anatomico-medicus de respiratione usuque pulmonum* (1667); *Allgemeene verhandeling van bloedeeloose diertjens* (1669); *Miraculum naturae seu uteri muliebris fabrica* (1672); and *Ephemeræ vitæ* (1675). H. Boerhaave published a collection of Swammerdam's manuscripts, *Biblia naturæ* (1737-38). (A. C. C.; X.)

**SWAMP**, a tract of saturated, miry, spongy ground occurring under conditions of impeded surface or internal drainage of substrata abundantly supplied with water from precipitation, groundwater, tides, or other sources, and which may be seasonally or perennially subject to flooding. Swamps are abundant and extensive on the low flat-lying terrain of seacoasts, lake basins, and stream valleys, may be widespread on uplands with low drainage gradients, and often occur on steep slopes where groundwater seepage is abundant. Development of swamps is favoured by wet climates but they are common in Arctic areas with permanent frost despite low precipitation.

In popular usage the term "swamp" indiscriminately includes bogs, marshes, fens, moors, heaths, muskegs, and other related terrain features, and may be distinguished from these commonly intergrading features only with difficulty even in local areas. Some characteristic properties of swamps include soft, mineral-rich substrata of well-mixed inorganic and organic fractions, little or no peat accumulation, absence of the floating mats of vegetation typical of bogs, relatively good aeration and filling by silting, or if by organic accumulation *in situ*, the materials added from the bottom upward.

Swamp vegetation is usually dense, of great variety, and, depending upon the stage of development in relation to the changing environment, may consist principally of herbaceous species (cat-tails, grasses, sedges), woody shrubs (willow, alder, buttonbush), coniferous trees (white spruce, bald cypress) or broadleaved deciduous trees (willow, cottonwood, sycamore, cotton gum, red maple).

Examples in the United States are the mangroves of coastal Florida, the partially marshy Dismal Swamp of Virginia and North Carolina, and the Okefenokee swamp of Georgia. See also MARSH. (M. E. B.)

**SWAN, SIR JOSEPH WILSON** (1828-1914), English physicist and chemist who invented the dry photographic plate and a prototype of the electric light, was born at Sunderland, in County Durham, on Oct. 31, 1828. After serving his apprenticeship with a druggist in his native town, he became first assistant and later partner in a firm of manufacturing chemists in Newcastle.

Among its operations was the manufacture of photographic plates, and thus Swan was led to begin the production of dry plates, the outcome of an original observation made by him on the effect of heat in increasing the sensitiveness of a gelatine bromide of silver emulsion. In 1864 he patented the first commercially practicable process for carbon printing in photography (see PHOTOC-RAPHY). In 1879 he patented bromide paper.

In 1860 he produced an electric lamp with a carbon filament which was formed by packing pieces of paper or card with charcoal powder in a crucible and subjecting the whole to a high temperature. The carbonized paper thus obtained he mounted in the form of a fine strip in an evacuated glass vessel and connected it with a battery to Grove's cells, which, though not strong enough to raise it to complete incandescence, were sufficient to make it red-hot. This was substantially the method adopted by Thomas A. Edison nearly 20 years later (see LIGHTING).

Subsequently Swan devised a cotton thread parchementized

by the action of sulfuric acid, and on Oct. 20, 1880, he gave at Newcastle the first public exhibition on a large scale of electric lighting by means of glow lamps. In another method devised by him, first exhibited in 1897, collodion was squirted into a coagulating solution and the tough threads thus obtained carbonized by heat (see *FIBRE: History*). He also devoted attention to apparatus for measuring electric currents, to the improvement of storage batteries, and to the conditions governing the electrodisposition of metals.

Swan was knighted in 1904. He died at Warlingham, Surrey, on May 27, 1914.

See K. R. Swan, *Sir Joseph Swan* (1947); C. Singer et al. (eds.), *A History of Technology*, vol. v (1958).

**SWAN**, a well-known relative of geese and ducks and one of the largest of waterfowl. As symbols of beauty, dignity, and immortality, swans figure widely in song, story, and mythology. Especially prominent are the stories of the swan maidens—half mortal, half supernatural—whose alliances with mortal men are romantic but invariably poignant and troubled. The last achievement of an artist is called a "swan song" in allusion to the plaintive song a swan, mute in its lifetime, is fabled to sing when dying.

Swans constitute the subfamily Cygninae in the family Anatidae. Although goselike in appearance, they are much larger (up to six feet long in the trumpeter swan) and have longer necks. They are most at home on water, where they feed on aquatic plants, but they also venture awkwardly onto land in search of grass and grain. The sexes have similar plumage. A cob (male) and pen probably mate for life. The nest, a bulky mound of vegetation on the ground, contains several pale-colored eggs, which, after about 35 days of incubation by both parents, hatch into brownish-white down-clad cygnets. Swans, like other anatids, are gregarious and form flocks except when breeding; they often fly in V-formation, especially when migrating.

Five white species live in the Northern Hemisphere; a black-necked swan, *Cygnus melancoriphus*, lives in southern South America; and a black one, *Chenopsis atrata*, lives in Australia and New Zealand, having been introduced into the latter country.

The common swan of ornamental ponds everywhere is the mute swan (*Cygnus olor*), up to five feet long, native to northern Europe and Asia and easily recognized by the knob on its forehead. It became a wild bird in Long Island, N.Y., after it escaped from estate ponds. Because of its pugnacious disposition and voraciousness, it poses a threat to other waterfowl.

American species are the Arctic-nesting whistling swan (*Olor columbianus*), a race of the Bewick's swan (*Cygnus bewickii*) of Eurasia, and the rare trumpeter swan (*O. buccinator*) of Montana, Wyoming, and western Canada. The latter was threatened with extinction but has increased and extended its range into southern Alaska. The whistling swan winters in large numbers in the Currituck Sound area of North Carolina and Virginia. On northward migration, flocks occasionally alight in the Niagara River and, unable to take flight as they are swept through the rapids, pass over the falls to their destruction. (DN. A.; X.)

**SWANAGE**, a seaside holiday town and urban district in the South Dorset parliamentary division of Dorset, Eng., 27 mi. (43 km.) ESE of Dorchester by road. Pop. (1961) 8,120. Area 4.3 sq.mi. It lies in a sandy bay backed by precipitous chalk cliffs with numerous caves. Swanage Bay was the scene of Alfred the Great's naval victory over the Danes in 877. Purbeck marble is still extracted from quarries first mentioned in 1250.

**SWANSEA** (ABERTAW), a municipal, county, and parliamentary borough and seaport of Glamorgan, Wales, lies at the mouth of the river Tawe on the north side of Swansea Bay. Pop. (1961) 167,322.

A. W. AMBLER FROM NATIONAL AUDUBON SOCIETY

MUTE SWAN (*CYGNUS OLOR*) AND CYGNET

The Via Julia from Nidum (Neath) to Loughor probably passed through the north of the borough, where Roman coins were found in 1835. The name Swansea stands for Sweyn's "ey" or inlet, and may have been derived from Sweyn I (Forkbeard), king of Denmark, who certainly visited the Bristol Channel. The earliest known form of the name is Sweynesse, which occurs in a charter granted by William, earl of Warwick, some time previous to 1134 in King John's charter (1215) it appears as Sweyneshe, and in the town seal, of medieval origin, it is given as "Sweyse." The Welsh name, Abertawe, first appears in Welsh poems of the beginning of the 13th century. The town grew up around the castle that Henry de Newburgh (or Beaumont) built in the early 12th century on the west bank of the Tawe. (See GOWER.) In the Civil War the town was Royalist until the autumn of 1645 when Colonel Philip Jones became its governor. The older part of the town (the whole of the municipal borough previous to 1836) occupies the west bank of the Tawe near its mouth and is now wholly given up to business. Stretching inland to the north along the river for about 6 mi. through Landore to Morriston, and also eastward along the sea margin toward Neath, is the industrial quarter, where the residential part occupies the sea front and the slopes of the Town Hill (573 ft. [175 m.] high) to the west, stretching out to Sketty. The attractive seaside resort of the Mumbles or Oystermouth and a large part of the Swansea rural district were included in the borough in 1918. The east side of the river is known as St. Thomas and Port Tennant.

The 12th-century castle has entirely disappeared, but portions of the new castle, which was probably intended only as a fortified house, are incorporated in certain town buildings. The remains include a tower, a so-called keep with the curtain wall connecting them, and a fine embattled parapet with an arcade of pointed arches in a style similar to that of the episcopal palaces of St. David's and Lamphey built by Henry de Gower (d. 1347), bishop of St. David's, to whom the building of the new "castle" is also ascribed. Traces of St. David's Hospital, built by the same prelate in 1331, are still to be seen at Cross Keys Inn. The parish church of St. Mary was entirely rebuilt in 1896-98, only to be destroyed in 1941 by an air raid. It has since been restored and was reopened in May 1959. Within the parish of St. Mary was St. John's, a church once owned by the Knights Hospitallers. This church, which was entirely rebuilt in 1820, was renamed St. Matthew in 1880, when a new St. John's was erected within its own parish. The Royal Institution of South Wales, founded in 1835, possesses a museum in which the geology, mineralogy, botany, prehistoric, and later antiquities of the district are well represented. Its library is rich in historical and scientific works relating to Wales and Welsh industries. The free library and Glynn Vivian Art Gallery (opened 1911) contain exhibits of local and general Welsh interest. Near the shore at the west end of the town is the new guildhall, opened in 1934. It is notable for containing Sir Frank Brangwyn's 16 panels depicting the peoples, flowers, fruits, and animals of the British Empire, originally painted for the royal gallery of the House of Lords as part of a peers' war memorial. The grammar school, founded in 1682 by Hugh Gore (1613-91), bishop of Waterford, was destroyed during an air raid (1941); a new Bishop Gore School was opened in 1952. The University College of Swansea was founded in 1920. Beau Nash, the dandy, was born in Upper Goat Street in 1674. The town has about 3,000 ac. (1,214 ha.) of open spaces.

**Industrial Development and Port Facilities.**—William de Braose's charter of 1306 gave the burgesses the right to take from the lord's woods sufficient timber to make four great ships at a time and as many small vessels as they wished. Cromwell in his charter of 1655 recognized Swansea as "convenient for shipping and resisting foreign invasions."

From about 1768 to 1850 Swansea had a famous pottery. Beginning with earthenware which twenty years later was improved into "opaque china," it produced from 1814 to 1823 superior beautifully decorated porcelain.

During the 18th century coal (which had been worked in the district as early as the 14th century) began to be mined at Llansamlet, and copper smelting (begun at Swansea in 17...

though at Neath it dated from 1584) assumed large proportions. The coal was conveyed on the backs of mules and later by means of a private canal. Under an act of 1791 harbour trustees cleared the river bed and built a long pier on either side of it. A canal connecting the tidal part of the River Neath with the mouth of the Tawe was made in 1789, and also a small dock, Port Tennant, or Salthouse Dock, near the east pier, which continued to be used till 1875. By 1798 the entire coal-producing Swansea Valley had been connected with the port by a canal 16½ mi. (27 km.) long (acquired by the Great Western Railway in 1872). In 1845 the river was diverted eastward into a new channel (called the New Cut), and its old channel was locked and floated in 1852, thereby forming the North dock. (Area 11½ ac., and a half tide basin 2½ ac. [1 ha.]. Length of quays 5,500 ft. [1,676 m.].) The South Dock, begun in 1852 and opened in 1859, is mainly used for shipping coal and general cargo and for discharging timber and fish. It has an area of 18½ ac. (7.5 ha.); length of quays 6,550 ft. (1,996 m.); depth of water in lock 34 ft. (10 m.).

The next development was in the east side of the river where the shore of Fabian's Bay, inside the harbour mouth, was extended for the construction of the Prince of Wales Dock (authorized 1874, opened October 1881, and subsequently extended), area 28 ac. (11 ha.); length of quay 6,872 ft. (2,095 m.). The very rapid increase in the demand for anthracite coal (for the shipment of which Swansea has practically a monopoly) soon necessitated still further accommodation, and in July 1904 was begun the King's Dock, which lies farther east and has an entrance direct from the bay. By means of the embankment made in connection with it, 400 ac. (162 ha.) were reclaimed from the sea. King's Dock and basin is 221 ac. (89 ha.); depth of water 40 ft. (12 m.) (high tide); length of quays 14,050 ft. (4,282 m.). The Queen's Dock, exclusively an oil dock, occupies 150 ac. (61 ha.). There are three dry docks, and the entire harbour has approximately 270 ac. (109 ha.) of deep water, more than 6 mi. of quays, and 130 mi. (209 km.) of railway sidings. Imports include crude oil, copper, nickel, iron, timber, grain, and rubber. Exports include coal, patent fuel, refined oil, coke, tin plate, and large quantities of manufactured goods.

Formerly acknowledged as "the metallurgical capital of Wales," Swansea is still an important seat of the copper, tin plate, and spelter or zinc industries. Three-fourths of the tin plate manufactured in Great Britain and a very high proportion of the spelter are made in the district. There are also important steel works, and light industries have been developed, notably on the Fforestfach industrial estate. In 1918 Swansea became an important centre for the distribution of oil, extensive storage and refining facilities (since enormously extended) being opened at Llandarcy.

**Administration.**—The town claims to be a borough by prescription because (although its charter of creation cannot be found or established) its status may be inferred from King John's charter of 1215 in which the inhabitants are addressed as "our burgesses of Sweyneshe." Its first grant of municipal privileges may have been in the charter of William, 3rd earl of Warwick, granted some time before 1184. In 1208 King John granted Gower by charter to William de Braose, whose descendant gave Swansea and Gower various liberties by a charter of 1306 (*see above*). These were confirmed by the earl of Worcester's charter in 1532. Cromwell's charter of 1655 changed the title of portreeve into mayor, but this lasted only until 1659 when the title of portreeve was resumed.

From 1535 to 1832 (with the exception of 1658–59) Swansea was one of several contributory boroughs sending only one member to parliament. In 1832 Swansea, with four other contributory boroughs known together as Swansea District, was again represented by one member. In 1885 the district was split into two divisions, Swansea Town and Swansea District, each returning one member. In 1919 a different division was made which still remains: Swansea West and Swansea East.

The assizes and quarter sessions for the administrative county of Glamorgan are held at Swansea and Cardiff alternately, but the borough has its own separate commission of the peace and quarter sessions. It became a county borough in 1888, and in 1923 the

Church in Wales created a bishopric of Swansea and Brecon. In February 1941 the whole business centre of the town (about 25 ac. [10 ha.]) was destroyed by air raids. It has now been rebuilt on modern lines. The main thoroughfares are the Kingsway, running east to west, and Princess Way, north to south. Shops and stores have been erected on these highways and have made Swansea the principal shopping centre for an area populated by 500,000 people.

The corporation has acquired and is operating an airport at Fairwood Common. This has been equipped with up-to-date appliances and is capable of dealing with all types of air traffic.

(T. B. B.)

**SWANTON, JOHN REED** (1873–1958), U.S. anthropologist, a foremost student of American Indian ethnology, was born on Feb. 19, 1873, in Gardiner, Me. He was educated at Harvard University (A.B. in 1896 and Ph.D. in 1900). Associated during the following 44 years with the Bureau of American Ethnology, Smithsonian Institution, Swanton's first important field work was among the Haida and Tlingit (*qq.v.*) Indians in 1901 and 1904 (Jesup expedition). He became the leading authority on tribes of the southeastern U.S., his interests touching on all areas of North American ethnology, including linguistic and theoretical problems. He was largely responsible for developing modern techniques in historical anthropology. Among his major works are *Final Report of the United States DeSoto Expedition Commission* (1939); *Indians of the Southeastern United States* (1946); *The Indian Tribes of North America* (1952).

Elected a member of the National Academy of Sciences, Swanton was president of the American Anthropological Association (1932) and editor of the *American Anthropologist* (1911, 1921–23). In 1948 he was awarded the Viking Medal, the highest professional honour in U.S. anthropology. He died on May 2, 1958, in Newton, Mass.

**BIBLIOGRAPHY.**—*Essays in Historical Anthropology of North America* (1940), published in honour of Swanton by the Smithsonian Institution; W. N. Fenton, "John Reed Swanton," *Am. Anthropol.*, vol. 61 (Aug. 1959); National Academy of Sciences, *Biographical Memoirs*, p. 329–349 (1960).

(M. W. Sr.)

**SWARTHMORE**, a borough of Pennsylvania, U.S., is a residential suburb of Philadelphia, in Delaware County, about 11 mi. (18 km.) SW of the city. The population (5,753 in 1960) is composed principally of the families of commuters to offices in Philadelphia and Chester. The community grew up around Swarthmore College, a coeducational institution founded in 1864 by the Hick-site body of the Society of Friends and since 1911 nonsectarian. It is noted principally for its system of honours courses initiated in 1921 by Frank Aydelotte (1880–1956), president of the college from 1921 to 1940. Those who qualify for this program participate in honours reading and research seminars in three chosen fields of concentration during their junior and senior years. On the campus is the two-and-one-half story gray stone house in which the artist Benjamin West was born. It was built in 1724 in the characteristic Philadelphia style of that era.

For comparative population figures *see table in PENNSYLVANIA: Population*.

(R. F. Wb.)

**SWAT**, a state forming part of the Malakand Agency in the Peshawar division of West Pakistan, adjoins the Mardan District in the valley of the Swat River. Area 2,934 sq.mi. (7,599 sq.km.). Pop. (1961) 614,395. Lying in a largely inaccessible region, Swat is reached by the Malakand, the Shah Kot, and other passes from the south. It is divided into two distinct parts: Swat Kohistan or mountain country, on the upper reaches of the Swat and its affluents as far south as Ain; and Swat proper, lower down, which is further subdivided into upper and lower parts.

The Yusufzais (or Afghans), who form the largest group of the population, are mainly concentrated in the lower valley, whereas Kohistan is peopled by Torwals and Garhwis. Fruit constitutes the chief export. Honey is also an important product, and the manufacture of curtains and woolen blankets is the principal cottage industry. Saidu, the capital, is 28 mi. (45 km.) NE of Malakand and is connected with it by a good road. It has a degree college, two high schools, and two hospitals. It is linked with Mingora, the chief commercial centre, by an asphalt road. Swat

accessed to Pakistan soon after the partition of India. Constitutional reforms were granted to the people in 1954, and in the same year the administration of the adjacent territory of Kalam (pop. [1961] 10,304) was also entrusted to Swat.

Swat has great historical interest as a region bordering on Europe and Asia. It was one of the conquests of Alexander the Great and was also a remarkable stronghold of the Buddhist faith. Recent archaeological excavations have revealed an old civilization possibly dating back to the 5th century B.C.

**SWAT RIVER**, a river in West Pakistan, which gives its name to the state of Swat. It is formed by the junction of the Gabral and Ushu rivers in Kohistan at Kalam. From there it flows almost due south as far as Chakdarra and then turns to the southwest and west until it is joined by the Panjkora. The united stream sweeps in a great curve southwestward to Abazai, where it emerges to the north of the Mohmand Hills into the Peshawar Plain and joins the Kabul at Nisatta after 400 mi. (650 km.). The river is utilized by canals to irrigate about 160,000 ac. (65,000 ha.). The valley, which is very narrow in the higher mountains, contains rich fertile tracts in Swat proper that are extensively cultivated. (K. S. Ad.)

**SWATOW** (SHAN-T'OU), a port city in eastern Kwangtung Province, People's Republic of China. Until it became a treaty port in 1869, Swatow had been a small fishing village 25 mi. (40 km.) downstream from the district capital at Ch'ao-chou (Ch'ao-an), reflecting the Ch'ing dynasty's policy of limiting coastal trade and movement and the fear of pirates. Foreign traders sought tea cargoes and, later, Chinese willing to work in the mines and plantations of Malaya and Singapore; many Swatow people have also gone to Thailand and Hainan island. Missionaries from Europe introduced lace and needlework in the 1890s, starting thereby the great industry that by 1937, the peak year, employed nearly 500,000 people and sent \$7,000,000 of finished goods to the U.S. alone. Typical products for Chinese markets include sugar, pineapples, oranges, pomelos, bananas, and fine grasscloth linen.

Swatow is built on the tip of a rocky point on the north side of the channel leading into the T'o River but is not directly connected with the larger Han River on the north. Behind the city is a crowded rice delta of about 600 sq.mi. (1,554 sq.km.), marked by many rocky hills. This site makes the late summer typhoons especially severe, the most damaging being that of 1922 when 50,000 boatmen and townsfolk were drowned by the wind-driven waves. Aside from the railway to Ch'ao-an, only roads and the shallow Han River connect Swatow with the interior. The population in 1953 was 280,400. (Te. H.)

**SWAZI**, Bantu-speaking agriculturalists and pastoralists, numbering about 410,000 and inhabiting Swaziland and part of the adjacent eastern Transvaal in the Republic of South Africa. Swazi culture is predominantly Nguni (*q.v.*), but the incorporation of original Sotho (*see* SUTO) occupants of the area has strongly influenced the political organization, rain ritual, and marriage regulations. Europeans did not defeat the Swazi by force, and much traditional culture persists within a modern framework.

The highest traditional powers (political, administrative, economic, and ritual) are shared between a hereditary male ruler (*Ngwenyama*) and his mother or a mother substitute (*Ndlovukati*). Marriage is by bridewealth (*q.v.*), and polygyny is the conservative ideal. The king's wives and children are settled in royal villages diplomatically dispersed throughout the territory. National officials are drawn from special clans, and a balance is maintained in local and central government between a well-defined aristocracy of birth and representatives of commoners. All important issues must be discussed by a central privy council (*liqoqo*) consisting mainly of royal clansmen, and a larger national council (*libandla*) attended by chiefs and headmen. The relationship of rulers and subjects is dramatically expressed in an annual ceremony, *Ncwala*, a ritualization of kingship. Cutting through local and kinship bonds are men's age classes, organized every five to seven years, for labour and other national services. Beliefs in magic and witchcraft interact within a highly organized ancestral cult. *See* also SWAZILAND.

**BIBLIOGRAPHY.**—B. A. Marwick, *The Swazi* (1940); H. Kuper, *An African Aristocracy* (1947), "The Swazi," *Ethnogr. Surv. Afr.*, pt. 1,

**SWAZILAND**, a British protectorate in southern Africa, administered by Her Majesty's commissioner resident in Swaziland. It is a compact country of 6,705 sq.mi. (17,366 sq.km.) surrounded on three sides by the Transvaal Province of the Republic of South Africa and on the east by Natal Province and Portuguese East Africa (Mozambique). The capital is Mbabane.

**Physical Features.**—Swaziland, lying on the eastern slopes of the great African plateau between the high veld and the coastal lowlands, falls naturally into four longitudinal regions. In the west the rugged edge of the high veld consists of steep quartzite ridges, ranging in altitude from 4,000 to 6,000 ft. (1,200 to 1,800 m.), and deep valleys cut in shales. A rainfall of 40–60 in. (1,000–1,500 mm.) occurs mainly in summer; the typical vegetation is temperate short grass. The middle veld, ranging from 1,500 to 4,000 ft. (450 to 1,200 m.), is rolling granite country with a rainfall of 25–40 in. (630–1,000 mm.) and a savanna vegetation of tall grass and scattered trees. Eastward, the granite hills dip gently beneath the younger sedimentary rocks of the low veld. This region is characterized by a relatively flat surface mostly 750–950 ft. (230–290 m.) above sea level; fertile soil; a low, highly variable rainfall (average about 20 in.) with a pronounced winter drought; and thorn-bush vegetation. In the east the volcanic Lebombo scarp rises abruptly from the Bushveld to form an undulating lava plateau averaging 1,500 ft. in altitude, with a moderate rainfall and a vegetation of short grass. The scarp is broken only by the deeply incised Mbuluzi, Usutu, and Ngwavuma rivers, which, with the Komati, drain eastward. (P. St.)

**History.**—According to the traditional account of the origin of the Swazi, when in the 16th century the main Bantu tribes were moving southward along the coast of what is now Portuguese East Africa, a chief named Dlamini broke away with a few followers and crossed the Lubombo Range into the area between the Pongola and Great Usutu rivers. Under pressure from the Zulus, the tribe moved northward to the Little Usutu. Further attacks by Zulus took place from time to time, and when King Sobhuza I died in 1836 his successor, Mswazi (Mswati) II, who reputedly gave his name to the tribe, moved farther north to the Pigg's Peak area. The Swazi now had a well-trained army and conquered the tribes to the north, but in 1846 their ruler ceded to the Lydenburg Republic whatever rights he had to the country north of the Crocodile River. It was at that time also that Mswazi was compelled to seek British aid against the Zulus.

During the 1880s large numbers of Europeans visited the Swazi king Mbandeni in search of concessions. He granted numerous concessions over land, minerals, grazing, timber, and even for railways, street lighting, collection of revenues, and exemption from taxation, but often with a formula designed to protect his sovereignty and the rights of the Swazi people.

In 1888 a charter of self-government was granted to the Europeans. Two years later, under a convention between the British government and the South African republic, a provisional government consisting of representatives of the two powers and a representative of the Swazi people was set up with the consent of the latter. In 1893 the British government signed a new convention permitting the South African republic to acquire from the Swazi regent and her council an organic proclamation conferring on the republic rights of jurisdiction, legislation, and administration, without incorporation in the republic. The Swazi refused to sign the proclamation, but in 1894 another convention was signed by the two powers, virtually giving effect to its terms. After the conquest of the Transvaal all rights and powers of the republic passed to Great Britain, and in June 1903 by an order in council under the Foreign Jurisdiction Act the governor of the Transvaal was empowered to administer Swaziland and to legislate by proclamation. In 1906 these powers were transferred to the high commissioner for Basutoland, Bechuanaland, and Swaziland. A commission was appointed in 1907 to deal with the problem of the concessions, and as a result of its report, land and grazing concessions were reduced by one-third.

The South Africa Act of 1909 provided for the possibility that Swaziland, along with the other high commission territories of Basutoland and Bechuanaland, might at some future date be incorporated in the Union of South Africa. The British government gave an assurance that the people of the territories would first be consulted and that the British Parliament would be given an opportunity to discuss the matter before any such change took place. Since then the South African government has several times asked for the transfer of the territories, but on each occasion the British government has made it clear that there could be no question of a transfer until the above conditions were fulfilled. In 1963 the office of resident commissioner was replaced by that of Her Majesty's commissioner (equal in status to governor); in 1964 the high commissionership was abolished. A constitution providing limited self-government was promulgated in 1963 (see below).

**Population.**—The estimated population at the end of 1963 was 287,900. At the census of 1956 the African population was 229,744, an increase of 26.7% since 1946; the European population was 5,919 (84.9% increase); and the Coloured population was 1,378 (84.9% increase). The large increase in the numbers of Europeans reflects the growing pace of development in the territory. There are European townships at Mbabane, Manzini (formerly Bremersdorp), Stegi, Goedegun, Hlatikulu, and Manikaana, and there are other European communities at Pigg's Peak, Emlembe (the Havelock asbestos mine area), Eranchi (the Swaziland irrigation scheme), Malkerns, and Big Bend on the Great Usutu.

The Swazi language (Siswati) is spoken by almost all Africans. The home language of 60% of Europeans is English and of 30% Afrikaans. English is spoken by 90% of Coloureds.

In the 1956 census 60% of the African population was recorded as Christian, divided among 24 denominations, the remaining 40% adhering to indigenous religions. (See also SWAZI.)

**Administration and Social Conditions.**—*Government.*—In the United Kingdom responsibility for the administration of the territory rests with the Colonial Office. Her Majesty's commissioner, resident in Swaziland, is the administrator, responsible directly to the Colonial Office. The constitution promulgated in 1963 provides for an Executive Council of eight members and for a Legislative Council comprising four official members, eight elected Swazi, eight elected Europeans, eight persons of any race elected on a national roll, and up to three members nominated by Her Majesty's commissioner. Elections for the Legislative Council were held in June 1964, and it met first on Sept. 9. In conformity with traditional law and custom, the Swazi king (*ngwenyama*) is advised by two councils, the larger of which includes all adult Swazi men. The office of the *ngwenyama* and most matters which are regulated by Swazi law and custom are excluded from the jurisdiction of the legislature. A committee was appointed in 1965 to work out a new constitution.

**Health.**—There were, in the mid-1960s, 4 government and 3 mission hospitals and 11 government clinics. There were also 24 clinics maintained by missions, 3 by the Swazi National Treasury, and others by large employers of labour for their employees. Among the principal diseases, tuberculosis and nutritional and deficiency diseases were prominent, but malaria had been brought under control by a campaign of hut spraying.

**Justice.**—There are in each district subordinate courts of the first, second, and third class. Swazi courts deal with matters affecting Swazi law and custom; they include courts of appeal and a judicial commissioner's court. There is a high court of Swaziland and a court of appeal for Basutoland, Bechuanaland Protectorate, and Swaziland. Swaziland has a small police force.

**Education.**—In January 1963 a policy of school integration was adopted, and schools can no longer be considered to be European, African, or Eurafican, as formerly. After the mid-1950s, there was a striking increase in the enrollment of Swazi children; by the mid-1960s, about 50,000 were attending approximately 370 schools; under 3,000 of them were in secondary schools.

**The Economy.**—More than half of the area of territory is available for occupation by Africans, the rest being held by European landowners.

**Agriculture.**—Largely through the efforts of the government agricultural demonstrators, there has been a great improvement in the agricultural methods of the Swazi farmer and consequently in crop yields. Livestock raising is important to the economy. Maize is the staple food of the Swazi and is the principal crop. The most important cash crop on unirrigated land is cotton. Sorghums are also grown, largely for beer making. Other crops are peanuts, tobacco, and beans. Rice is being grown on an increasing scale by European farmers and is an important export. In 1953 pineapple planting started on a fairly large scale, and a canning factory was set up; pineapples are successfully grown in the Malkerns Valley. The tung oil industry has declined considerably because of the fall in world prices. Sugarcane is grown on a large scale in irrigated areas. Plantings of citrus are also in the Malkerns area, where soil and climate seem well suited for it.

Swaziland offers ample scope for irrigation from its large rivers. There are three important irrigation projects: Malkerns, controlling 10,000 ac.; Big Bend, 10,000 ac. (4,000 ha.); and the Swaziland Irrigation Scheme, 16,000 ac. (6,500 ha.).

**Forestry.**—Swaziland's forests are almost wholly man made. By the mid-1960s the Commonwealth Development Corporation had planted more than 225,000 ac., of which about 180,000 were pine. The Usutu forests reached the production stage in 1961.

**Industry and Mining.**—By the early 1960s the Usutu pulp mill, designed to produce 100,000 tons of pulp a year, was in operation; pine logs at Peak Timbers were turned into chipboard; two sugar mills (85,000 tons of sugar) were in full production; and the pineapple industry was prospering. A project to export to Japan, via Lourenço Marques, iron ore from the rich deposits at the Bomvu Ridge near Mbabane led to construction of the country's first railway (formally opened in November 1964), to the existing railhead on the border of Portuguese East Africa.

The Havelock mine in northwestern Swaziland is a large producer of asbestos, one of the territory's three most important exports. Other mineral production, including tin, gold, barytes, and diaspore, is comparatively small, though there are extensive coal deposits in the eastern Bushveld.

**Finance.**—The main sources of ordinary revenue are income tax (levied on non-Africans only), customs and excise (under a customs union agreement signed in 1910 with the Republic of South Africa, Swaziland receives 0.149% of the total collection of the republic), African tax, base metal royalties (mainly from asbestos), and posts and telegraphs. Swaziland receives nearly one-quarter of its total revenue in grants from the Colonial Development and Welfare Fund. Chief items of expenditure are education, public works, administration, and land utilization. Currency is that of the Republic of South Africa (2 Rands = £1 sterling = \$2.80).

**Communications.**—In addition to the railway to Portuguese Africa, a £1,250,000 program of road improvement was begun in 1962. There are freight and passenger services by road. Swaziland has its own postal, telegraph, and telephone facilities.

**SWEATING SICKNESS.** This disease, also known as the English sweat, appeared in England as an epidemic on six occasions—in 1485, 1506, 1517, 1528, 1551, and 1578. It was confined to England, except in 1528–29, when it spread to the continent of Europe, appearing in Hamburg, and from there passing northward to Scandinavia and eastward to Lithuania, Poland, and Russia; the Netherlands also were involved, but the disease did not spread to France or Italy.

Apart from the second outbreak, all the epidemics were severe, with a very high mortality rate. The disease was fully described by the distinguished physician John Caius, who was practising in Shrewsbury in 1551 when the last outbreak of the sweating sickness occurred. His account, *A Boke or Councell against the Disease commonly called the Sweate, or Sweatynge Sicknesse* (1552), is the main source of knowledge of this extraordinary disease.

The illness began with rigors, headache, giddiness, and severe prostration. After one to three hours, violent, drenching sweat

came on, accompanied by severe headache, delirium, and rapid pulse. Death might occur from 3 to 18 hours after the first onset of symptoms; if the patient survived for 24 hours, recovery was usually complete. Occasionally there was a vesicular rash. Immunity was not conferred by an attack, and it was not unusual for patients to have several. Each epidemic lasted for only a few weeks in any particular locality.

Since 1551 the only outbreaks of a disease resembling the English sweat have been those of the Picardy sweat, which occurred frequently in France between 1718 and 1861. In this illness, however, there was invariably a rash, lasting for about a week, and the mortality rate was lower.

It is difficult to know what the sweating sickness really was. Caius attributed it to dirt and filth. All the epidemics occurred in late spring or summer, so it may very well have been spread by insects. The disease seemed to be more severe among the rich than among the poor, and the young and healthy were frequent victims. It is unlikely to have been a form of influenza or typhus.

R. Merliss (1952) identified it with relapsing fever (*q.v.*), which is spread by lice and ticks and has many characteristics in common with sweating sickness. This explanation is certainly plausible. It is improbable that sweating sickness should appear as a well-defined disease and then vanish altogether.

Senf, "Ein Kartographische Beitrag zur Geschichte des Englischen Schweisses," *Kyklos*, 3:273 (1930); R. Merliss, "The Sweating Sickness," *Med. Arts Sci.*, 6:445 (1952). (O. G. E.)

**SWEATSHOP**, a term used to describe a workplace where conditions are oppressive and where there is unbridled exploitation of the workers. In England, the word "sweater" was used as early as 1850 to describe an employer or middleman who exacted monotonous work at very low wages. Charles Kingsley in his novel *Alton Locke* (1850) and in his political pamphlets directed attention to London "sweaters"; and the philanthropic London journalist Henry Mayhew in 1851 talked of "the sweating system." There were complaints of sweating in the United States also, beginning at the time of Civil War, when soldiers' wives were employed to make uniforms. It gained in intensity during the 1880s when immigrants from eastern and southern Europe provided a large source of cheap labour. In continental Europe the same conditions were present; and with the development of industrial production in Latin America and in Asia the problem emerged there also.

Certain conditions are necessary for sweating to be possible: (1) a mass of unskilled and unorganized labourers, often including women and children; (2) imperfect systems of management, which totally neglect the "human factor"; (3) ignorance of conditions or lack of will to intervene on the part of the state. Historically these conditions have been associated with the survival of home work and the development of contracting. Individual workers or groups of workers contract to do a certain job for a certain price. Sometimes they carry out this contract themselves; sometimes they let it out to subcontractors at lower prices. Contracting makes possible labour exploitation, often of women and children; and it produces erratic employment. When trade is brisk, extremely long hours are worked in seriously overcrowded workrooms or dwelling houses. When trade is slack, subcontractors, whose overhead costs are far lower than those of factory employers, dismiss workers without scruple. One of the earliest objectives of factory and minimum-wage legislation was to eliminate such exploitation.

Contracting and subcontracting are common in the garment manufacturing industry. In the 19th century, outwork existed in other industries, such as boot-and-shoe manufacture, soapmaking, cigar making, and the making of artificial flowers. Although legislation had by the middle of the 20th century either eliminated or carefully controlled sweating in most highly developed countries, the system was still operating in many countries in Asia, where larger numbers of people were engaged in home work than in industrial establishments.

Conditions tend to be worse in large cities, where sweatshops

are hidden away in slum areas and are aggravated by influxes of cheap labour from outside. To the native poor engaged in tailoring in London in the 1880s, for example, was added a large immigrant labour force of unskilled foreigners. In the United States the tireless search for cheap labour encouraged such immigration until 1917.

The first large-scale official inquiry into the sweating system was carried out in England by a select committee of the House of Lords. Its report, published in 1890, described conditions in tailoring, bootmaking, furriery, shirt making, mantle making, cabinetmaking, cutlery and hardware manufacture, chainmaking and nail making, saddlery and harness making, military accoutrement establishments, and dock labour. It claimed that sweating involved: (1) a rate of wages inadequate in terms of work done or basic standard of living; (2) excessive hours of labour; and (3) insanitary conditions in the houses or domestic workshops in which the work was carried on.

The inquiry of the select committee did not bear fruit immediately. It was not until 1909 that the Trade Boards Act set up boards to fix minimum wages in specified industries such as machine-made lace manufacture and chainmaking. In 1918 the scope of the act was extended to cover any trade where the Ministry of Labour considered that machinery for the effective regulation of wages was inadequate. Government interference was important, chiefly because it permitted the development of collective bargaining. By 1939, though many workers still received low wages, there were no longer any sweated trades in Great Britain.

In the United States most of the pressure to eliminate sweating was applied by organized labour. A number of acts, culminating in 1882, prohibited Chinese immigration. In 1889 the tobacco workers in New York obtained the passage of a state statute forbidding all manufacture of tobacco in any tenement house; but this was held unconstitutional by the New York Court of Appeals and home work was prolonged for a number of years. Beginning with Massachusetts in 1912, a number of states passed laws creating wage boards or commissions. The U.S. Supreme Court, however, in *Adkins v. Children's Hospital* (1923) held that a U.S. statute authorizing a wage board in the District of Columbia to fix minimum wages of women and children violated the guarantees of the due process clause of the Fifth Amendment of the U.S. Constitution, since freedom to contract between the employer and the employee was impaired. The *Adkins* decision was reversed by the court in 1937 in the *West Coast Hotel Co. v. Parrish* decision. Many states were prepared to intervene in the labour market, and their action was supported not only by organized labour but by voluntary organizations, such as the National Consumers League. By 1939 practically all states had limited the hours of labour for women, and several had introduced legislation prohibiting night work.

Four main factors contributed in other countries as well as in Great Britain and in the United States to the control of sweated industries: (1) social idealism; (2) the pressure of trade unions; (3) the extension of the franchise and the growth of labour parties; and (4) the growing economies of factory production and the increased interest in human relations in industry. In several countries there developed a tendency to let industries, in which both labour and management were strong, set their own standards. In unorganized and sometimes unorganizable industries the state intervened directly. The International Labour Organization was active in attempting to raise labour standards in countries where sweatshops were still common.

**SWEDEN** (SVERIGE), a kingdom of northern Europe, occupying the eastern and southernmost parts of the Scandinavian Peninsula and including the Baltic islands of Öland and Gotland (*qq.v.*). The length is about 1,000 mi. (1,610 km.), the extreme (mainland) breadth about 250 mi. (400 km.), and the total area, inclusive of inland waters, is 173,665 sq.mi. (449,793 sq.km.). Of this, 14,878 sq.mi. (38,535 sq.km.), or 8.6%, consists of about 100,000 lakes, of which the four largest are Vänern, Vättern, Mälaren (*qq.v.*), and Hjälmaren. The combined area of these four is

3,522 sq.mi. (9,121 sq.km.). The boundary length of Sweden is estimated at 6,100 mi. (9,817 km.), of which 4,724 mi. are coastal, 1,030 mi. common with Norway, and 347 mi. with Finland. The capital is Stockholm (q.v.).

## I. PHYSICAL GEOGRAPHY

**1. Structure and Relief.**—*The Baltic Shield and Caledonian Mountain Range.*—Almost the whole of Sweden forms part of the Baltic Shield with rock of Archean age. This extends to much of Norway and merges eastward, in Finland and the U.S.S.R., into the Russian Platform. The western edge of the shield experienced great folding and thrusting during the Caledonian orogeny,

and thus Sweden shares many structural features with Norway. In particular, the highest mountain areas lie along the Norwegian frontier, forming the "keel" (*kölen*) of the peninsula. These are of Caledonian origin although they later experienced considerable denudation, and in places the older rocks are overlain by more recent sediments which are certainly post-Silurian and possibly of Rhaetic age. The highest individual peaks are in the central zone of this Caledonian Massif, known as the Seve Nappe. Kebnekaise, 6,965 ft. (2,123 m.), and Sarek, 6,857 ft. (2,090 m.), are the two highest. Both are in Norrbotten, north of the Arctic Circle.

*Norrland and the Bothnian Coastal Plain.*—Between the Caledonian mountains and the Baltic and roughly north of latitude 60° is the Norrland terrain of Archean rocks, mostly granites and gneisses, which gradually slope down from the high mountains toward the Baltic and form part of the Baltic Shield (*see PRECAMBRIAN TIME: Europe*). The northern half of this region consists largely of plains out of which rise isolated, rounded hills, but the southern half has an irregular relief of mountains or hills separated by fairly deep valleys. Norrland is flanked on the east, from Umeå northward to the Finnish border, by a narrow coastal plain, which because of isostatic readjustment is an area that has risen from beneath the waters of the Gulf of Bothnia, the northern arm of the Baltic Sea. This coastal stretch within the Archean zone is an area of depression in comparison with the Norrland area of elevation.

*The Central Lowlands.*—Southward from Söderhamn the coastal plain reappears and forms a second area of depression—central Sweden. The northern boundary of this area runs southwest from Söderhamn to west of Örebro, and then passes to the north of Lake Vänern. To the south, it is bounded by a line roughly following latitude 58°, north of Göteborg, through Lake Vättern and south of Norrköping. The rock types are still Archean granites and gneisses, but much of the area is covered by glacial deposits and includes Sweden's largest plains. To the northeast is the Uppsala plain, which merges southward into the gently undulating region of Södermanland with its numerous small rock outcrops and lakes of which Mälaren, with Stockholm at its eastern end, is the largest. Two other flat areas are the Västgöta plain, with Vänern (2,156 sq.mi. [5,585 sq.km.]), the largest lake in western Europe, in its centre, and the Östgöta plain, stretching from Lake Vättern to the Baltic. Between these three lowland areas, and bordering the Västgöta plain on its western side, are regions of low hills with considerable local relief, caused by faulting resulting in horsts (*see FAULT*).

*South Sweden.*—South Sweden consists largely of gneisses in the western half and granites in the eastern, but this geological distinction is scarcely reflected in the present relief. In fact, in contradistinction to the geology, this area is divided according to relief into two approximately equal halves by a line drawn roughly west-east. The more northerly of these halves comprises the South Swedish Highlands, rising to about 1,000 ft. (300 m.) above sea level especially near the southern end of Vättern, where Tomtabacken reaches 1,237 ft. (377 m.). This area slopes gently down to merge in the south into the very level south Småland Archean plain with an average elevation of about 500 ft., which on the east merges into a sub-Cambrian peneplain that in turn disappears beneath Cambrian rocks reaching to the Baltic coast; to the west are the narrow, complex areas of south Bohuslän, the Göteborg archipelago, and the small coastal plain of part of Halland.

*Skåne.*—This small area in the extreme south of Sweden is of great significance. It lies outside the Archean region and belongs geologically to Denmark and continental Europe, with their Cretaceous rocks. The fault, probably mainly of Variscan age, which divides it from the remainder of Sweden, could be considered to be one of the most important of European boundaries, separating the old rocks of Fennoscandia (almost all older than 300,000,000 years and most of them twice that age) from the much younger, 100,000,000-year-old, rocks to the southwest. This fault runs roughly northwest and southeast through the university town of Lund. As is always the case in such circumstances, however, it

FIG. 1.—MAJOR PHYSICAL FEATURES OF SWEDEN

is in reality complex, so that to the northeast there is a parallel belt of fault-produced horst ridges, some 20 mi. (30 km.) in width. These are in Archean rocks, but the earth movements that produced them, although starting in Variscan times, continued to be active probably to Alpine times. In Skåne there is thus both the most recent solid rock in the country and also this unique boundary zone, producing a topography unique in Sweden.

**2. Glaciation.**—The present topography of Sweden owes much to the Ice Ages of the last half-million years. The Gulf of Bothnia was the main centre of European glaciation, and here the ice is considered to have reached a thickness of some 8,000 ft. (2,400 m.). At periods of maximum glaciation there was a slow outward movement of ice, but the more apparent modifications to the relief were made during lesser glaciations, when individual glaciers occupied the preglacial river valleys, radically altering their form.

and in the vicinity of Umeå by as much as 40 in. (1 m.) a century. This means a continual increase in land area, as more and more sea floor rises out of the water. The Stockholm archipelago is at a typical intermediate stage, only the shallower parts having so far become dry land.

**3. Climate.—Temperatures.**—The climate of Sweden is largely transitional between the maritime Atlantic coastland climate and the continental climate of farther east. It shows the variations to be expected in a country which spans  $13\frac{1}{2}^{\circ}$  of latitude, with  $2\frac{1}{2}^{\circ}$  within the Arctic Circle, and which is bounded on its western side for two-thirds of its length by mountains rising generally more than 5,000 ft. (1,500 m.) and in places reaching nearly 7,000 ft. (2,100 m.). The effect of the mountains is shown by comparing the temperatures of two places, one on either side of them. Haparanda is at the extreme northern end of the Gulf of Bothnia, and

Great glacial troughs or U-shaped valleys, rock hollows now occupied by lakes, such as Torneträsk in northern Lapland (Lapland), and all the other features of intense glacial action in a highland region were produced in the mountains. In the highest of these, glaciers still exist; the most southerly is in Härjedalen, where the snowline is at 4,450 ft. (1,350 m.). In the far north of Sweden the snowline is at 2,900 ft. (880 m.) and the largest ice-field is Sulitelma, with an area of 8.5 sq. mi. (22 sq. km.).

In Central and South Sweden the most notable glacial features are concerned with deposition rather than with erosion, and probably 80% of the whole country is covered with morainic material. The most important is ground moraine left by the retreating ice sheets, and it is on this that almost all the agriculture of the country is located. Much of it was deposited beneath water, for at the time of the last major deglaciation what is now the Baltic reached to the ice margin. The end moraines of the same period derive their special characteristics from this, and the topography of the Uppsala region is unlike anything that can be seen elsewhere in Europe, for ground moraine deposited as lake (or sea) floor alternates with small end moraines. Here, too, are exceptionally large and long eskers (ridges of morainic material deposited by subglacial streams fed by ice meltwater). They reach 160 ft. (50 m.) in height and some are more than 60 mi. (100 km.) in length.

The great weight of the Scandinavian ice sheet was sufficient to depress that area of the earth's crust, and since it melted away the land has gradually been recovering its original level. It appears to have completely done so in southern Sweden, but in the Stockholm district it is still rising at the rate of 16 in. (40 cm.)

Røst Island, in the Lofoten group off northwestern Norway, is some 130 mi. farther north and thus by latitude might be expected to be a little cooler. Both are very nearly at sea level. The mean temperature during January is  $-10.3^{\circ}\text{C}$  ( $13^{\circ}\text{F}$ ) at Haparanda, as compared with  $1.5^{\circ}\text{C}$  ( $35^{\circ}\text{F}$ ) at Røst, a difference of nearly  $12^{\circ}$  ( $22^{\circ}$ ). Corresponding summer temperatures are  $16.3^{\circ}\text{C}$  ( $61^{\circ}\text{F}$ ) for Haparanda and  $10.8^{\circ}\text{C}$  ( $51^{\circ}$ ) for Røst. The winter warming effect of the North Atlantic Drift and the summer cooling by North Atlantic waters, both important at Røst, are thus relatively absent at Haparanda, and the more extreme climate on the eastern side of the mountains is well demonstrated. The seasonal change from winter to summer is  $27.2^{\circ}\text{C}$  ( $49^{\circ}\text{F}$ ) at Haparanda, whereas in the milder, oceanic climate of Røst the difference is only  $9.3^{\circ}$  ( $17^{\circ}$ ). The annual precipitation, too, is strikingly different. Haparanda has less than 21 in. (530 mm.), while Røst has 28 in. (710 mm.); on the Norwegian coast within the influence of the mountains this figure rises to more than 160 in. (4,060 mm.).

These data contrast with those for two corresponding southerly stations, such as Esbjerg (Fanø) on the west coast of Denmark, and Växjö, at a height of 650 ft. (200 m.) in central South Sweden. Esbjerg has a January mean of  $0.7^{\circ}\text{C}$  ( $33^{\circ}\text{F}$ ) and Växjö  $-1.8^{\circ}$  ( $29^{\circ}$ ); the July temperatures are respectively  $15.7^{\circ}$  ( $60^{\circ}$ ) and  $16.5^{\circ}$  ( $62^{\circ}$ ). The similarity of these figures for the two localities makes the effect of the absence of the intervening mountain range very clear. The two main centres of population, Stockholm and Göteborg, have mean temperatures of  $-2.5^{\circ}\text{C}$  ( $28^{\circ}\text{F}$ ) and  $0^{\circ}$  ( $32^{\circ}$ ) respectively for January, with  $16.9^{\circ}$  ( $62^{\circ}$ ) and  $17.1^{\circ}$  ( $63^{\circ}$ ) for July.

Although the mountains on the west cut off most of the ameliorating effect of the southwesterly weather that would otherwise cross those areas into Sweden, the lowland has a much more equable climate than corresponding latitudes in the U.S.S.R., because of the drift of southwesterly air streams and pressure systems across the Skagerrak and Denmark, over southern Sweden, and northward. Nevertheless, the whole area is exposed to the approach of cool air from the northeast.

In the north, because of the long daylight hours, the summers are milder than might be expected. At Karesuando, on the Finnish border, at latitude  $68^{\circ}27'\text{N}$ , there is the possibility of perpetual sunlight from May 26 to July 18, and the absence of night cooling has the effect of producing a considerable accumulation of warmth and a 24-hour growing period daily for vegetation. Correspondingly, there is permanent darkness in the winter months and a progressive cooling until the sun returns in the spring. These effects lessen toward the south. The low angle at which the sun sets at many times of the year also produces a long twilight, both in the evening and morning, and again the daylight is lengthened. The growing season, taken as the average period during which the mean temperature is above  $3^{\circ}\text{C}$  ( $37^{\circ}\text{F}$ ), is often longer than might be expected from the latitude. At Karesuando it lasts from May 18 to Sept. 24, at Haparanda from May 6 to Oct. 7, at Stockholm from April 11 to Nov. 6, and at Växjö from April 5 to Nov. 8.

**Precipitation.**—The annual precipitation for almost the whole of lowland Sweden south of Haparanda varies between 20 and 30 in. (500–750 mm.), with the western side wetter than the eastern; in a small area west of Växjö it reaches 40 in. There is precipitation in all months, but June, July, and August are the wettest. North of Haparanda the annual precipitation is less than 20 in. In these northern areas much of the precipitation is in the form of snow, and at Karesuando the ground is snow-covered on the average from the end of October to the end of May.

**Ice Conditions.**—The Gulf of Bothnia freezes in winter. Aided by the low salinity, ice begins to form along the shores of the northernmost part during November, closing the harbours of Luleå and similarly sited ports from mid-December to mid-May. Ice reaches the coast in the Gävle and Stockholm districts much later, generally not until January, and Gävle is closed to shipping from about mid-February to early April. Stockholm is not normally closed. The ice spreads seaward from the coast and covers the whole width of the gulf as far south as Sundsvall by about mid-February. There is often a complete bridge of ice across the neck

of the gulf by the Åland Islands (Åhvenanmag Islands) by mid-February, but between this and the latitude of Sundsvall the central part of the gulf (between Sweden and Finland) remains covered only with broken ice. The extent, both in time and area, of the icing is extremely variable from year to year, and the above are averages for many winters. The usual thickness of ice along the coast of the gulf is about 30 in. (76 cm.), increasing to twice that in the far north. (R. K. GR.)

**4. Vegetation.**—The Swedish vegetation can be divided into four regional groups.

The marine region comprises belts on the coasts and in the sea with an algae vegetation: the intertidal belt, with seaweeds and aquatic vascular plants (*Najas* and *Zostera*); the sublittoral belt, often reaching depths of 100 to 150 ft. (30–45 m.), with brown algae dominating in the upper and red in the lower parts; and the eulittoral belt with only scattered colonies of red algae.

The bare regions—maritime, continental, and alpine—are treeless. The maritime region consists of heaths with dwarf shrubs (e.g., heather, bilberry, black crowberry); grass heaths with sheep's fescue and wavy hair grass; meadows, fens, and, on rocks and boulders, lichen communities. The continental, a steppe region, is found especially on Öland and Gotland and in eastern Skåne, and is conditioned by dry and warm summers; the steppes are rich in grasses, rockroses, *Anthericum*, and orchids, and their area has been increased by deforestation, burning, and heavy grazing. The alpine bare region comprises the areas above 2,000 ft. (about 600 m.) in northernmost Sweden and above 2,500–3,000 ft. in Dalarna. Its lower belt has shrublike willow, dwarf birch, blueberry and other *Vaccinium* species, *Cassiope*, *Dryas*, grasses, heath, and meadow vegetation; and in its upper belt, dwarf willow buttercup (*Ranunculus glacialis*), mosses, and lichens are characteristic; in its highest parts the soil is often entirely naked.

The coniferous forest regions cover the larger part of the country; the northern region reaches southward to about  $61^{\circ}\text{N}$  and has mostly spruce and Scots pine, with some birch, aspen, and rowan, or mountain ash; the southern reaches southward to the limit of the beech forests and has oak, beech, and birch; in both regions species of *Vaccinium*, moss, and lichen are characteristic and large areas, especially in the west, are occupied by raised bogs and fens.

The broad-leaved forest regions are the subalpine birch region and the beech region. The former holds a zone above the coniferous forests in the higher mountains with mountain birch dominating. The beech region comprises Skåne and parts of Blekinge and of the west coast; its other most important trees are pedunculate and sessile oaks, hornbeam, elm, ash, and maple. In acid soils the lower vegetation layers have heath character with *Vaccinium* species and wavy hair grass; in alkaline areas they are developed as meadows with anemone, yellow archangel, fumitory, ramson, and several grasses and sedges.

Although most of Sweden's plant species are postglacial immigrants from the south, some, for example, the spruce, have come from the east. Probably certain alpine species have survived at least the last glaciation in nunataks at the Norwegian coasts. In recent time the vegetation has been much changed by the planting of conifers in former broad-leaved forest areas, and by draining and cultivation of fens, etc. (A. H. W.)

**5. Animal Life.**—The mountain hare, various shrews, the ermine, weasel, red squirrel, fox, and elk are common to the entire country. The bear is protected and, with the wolf, wolverine, and lynx, is restricted to the northern forests. The wild reindeer is extinct, but there are large domesticated herds in Lapland. The elk is the most valuable game animal, but badger, otter, and the rare pine marten of the coniferous forests are hunted for their skins, as are the thriving wild descendants of escaped farm mink. The roe deer is scattered over the southern and central parts of the country with a tendency to spread northward. The Arctic fox and the lemming are confined to the northern highlands. The common porpoise is the only cetacean occurring in the Baltic, and with the gray seal it is held responsible for damage to fisheries.

Bird life is abundant, especially in spring and summer, several types such as the teal, snipe, golden plover, and wagtail being

found throughout the country. In the northern mountains the ptarmigan is common; waterfowl frequent the lakes; the golden eagle, certain buzzards, owls, and the small Lapland bunting are found. In the coniferous forests, grouse, capercaillie, and woodcock, the principal game birds, are now less common; the crane lives in marshy clearings; birds of prey, as well as crows and many other passerines, range over a wide area. In the midlands, partridges and doves are fairly common. On the coast are large numbers of gulls and terns, also eider duck and the rare sea eagle. There are very few reptiles or amphibians, and the viper is the only poisonous snake. The rivers and lakes are generally well stocked with salmon, trout, char, pike, and perch. Off the west coast, cod, flatfish, mackerel, and herring, including sprat, are caught. In the brackish waters of the Baltic both salt- and freshwater forms are found, and a small herring called strömming is caught in great numbers. The crayfish occurs in many places in Central and South Sweden. Among the lower marine animals a few types of Arctic origin are found, not only in the Baltic but even in Lakes Vänern and Vättern, having survived the changes consequent on the separation of the Baltic Sea and the Arctic Ocean.

Insects are common, even in the north. In summer in the northern lowlands the gadfly drives the reindeer to the upper pastures and snowfields. (MA. BU.)

## II. THE PEOPLE

**1. Physical Types.**—The Swedes are a markedly homogeneous people, characterized to a certain extent by typically "Nordic" traits—long slim bodies, long oval faces, straight blond hair, and blue eyes. Another strain, of uncertain prehistoric origin, with heavy, short bodies, is noticeable, for example, in Dalarna. More recently assimilated were Finns, who colonized remote woodlands in Central Sweden in the 16–17th centuries, and Walloons brought in as ironworkers early in the 17th century. Some Finnish customs and folk beliefs and Walloon family names and physical traits remain as evidence of these immigrations. The many refugees, mainly Balts, who fled to Sweden after World War II seem to have been rapidly assimilated. In the far north there are small minorities of Lapps (*see LAPLAND*) in the mountain areas and of Finns on the Finnish border (together about 0.7% of the total population).

**2. Language.**—Modern Swedish derives from the common Norse language of the Viking age and is closely related to Danish and Norwegian, although having greater phonetic resemblance to the latter. The Lapp and Finnish minorities in the north have retained their own languages. (*See further SWEDISH LANGUAGE.*)

**3. Religion.**—Sweden was converted to Christianity during the 9th–11th centuries, mainly by English and German missionaries. The established church, to which 95% of the population belongs, is Lutheran, and is divided into 13 dioceses including the archbishopric of Uppsala (founded 1164). Much of the medieval ritual survived the enforcement of the Reformation by Gustáv Vasa (Gustavus I), and the modern church presents a varied picture. Roughly, it may be said that in the north the Low Church dominates, in the southwest the High Church, and in Central Sweden the Free Churches, whose growth was encouraged by 19th-century revivalism. Constitutional religious freedom was extended by an act of 1952 which recognized the right of nonadherence to any church whatever. In 1965 there were about 345,000 Protestant dissenters, 35,500 Roman Catholics, and 13,000 Jews. Since 1958 women have been permitted to take holy orders in the established church.

**4. Customs and Culture.**—For long the Swedes were a nation of peasant farmers, and traditions of the old way of life have survived in the country districts. Southern and northern types of artifacts, social organization, customs, beliefs, and popular poetry reflect variations in natural conditions and in the intensity of farming and stock raising within Sweden's vast extent. In the south, however, differences between east and west are mainly the result of external cultural influences.

With the introduction of enclosures in the first half of the 19th century and the emergence of industrialism after 1870, the ex-

tremely conservative forces represented by the large villages and the self-sufficient farms disappeared, and at the same time improving communications and more extensive popular education made for uniformity. Traditions of a local character survived longest in certain parts of Härjedalen, in upper Dalarna, in southwest Småland, and in east Skåne. There is an interest, both artistic and historical, in preserving local traditions; extensive work in recovering folklore has been carried out, and Sweden has numerous folklore museums, of which the largest is Nordiska Museet in Stockholm.

Increasing urbanization has not lessened the Swedes' enthusiasm for the great open spaces of their country. Outdoor activities play an important part in modern Swedish life, and much use is made of cabins in the mountains and forests and among the skerries. Favourite forms of organized sport are association football (soccer), skiing, skating, ice hockey and bandy, sailing, rifle shooting, and *orientering* (cross-country running with map and compass). (S. Sv.)

## III. HISTORY

### A. FROM THE PREHISTORIC PERIOD TO C. A.D. 900

**1. Earliest Peoples and Cultures.**—The first migrations into Sweden probably occurred toward the close of the last glacial epoch (c. 12000 B.C.), when tribes of reindeer hunters roamed across the land bridge which joined Sweden with the continent. From the early postglacial period there are traces of occupation. Finds in the peat mosses of Skåne show a typical food-gathering culture, which later (c. 5000–3500 B.C.) spread throughout southern Sweden. New tribes, practising agriculture and cattle rearing, made their appearance about 2500 B.C., and soon afterward a peasant culture with good continental communications was flourishing in what are now the provinces of Skåne, Halland, Bohuslän, and Västergötland. The so-called Boat-Ax culture (an outlier of the European Battle-Ax cultures) arrived about 2000 B.C. and spread rapidly. During the Late Neolithic period southern and central Sweden display the aspects of a homogeneous culture, with central European trade links; in northern Sweden the hunting culture persisted throughout the Stone and Bronze ages.

The Early Bronze Age (from c. 1500 B.C.) was also characterized by strong continental trade links, notably with the Danube basin. Stone Age burial customs (skeleton sepulture, megalithic monuments) were gradually replaced by cremation. Rock carvings suggest a sun cult and fertility rites. Upheavals on the Continent combined with Celtic expansion (*see CELT*) seem to have interrupted (c. 500 B.C.) bronze imports to Scandinavia, and a striking poverty of finds characterizes the next few centuries. The climate, comparatively mild since the Neolithic period, deteriorated, necessitating new farming methods. At this time iron reached the north.

For the Early Iron Age (c. 400 B.C.–c. A.D. 1) the finds are also relatively scanty, showing only sporadic contacts with the La Tène (q.v.) culture, but they become more abundant from the Roman Iron Age (c. A.D. 1–400) onward. The material from this period shows that Sweden had developed a culture of its own, although naturally reflecting external influences.

Trade links between the Roman Empire and Scandinavia gave Rome some knowledge of Sweden. The *Germania* (written A.D. 98) of Tacitus gives the first description of the *Sviones* (Swedes), stated to be powerful in men, weapons, and fleets. Other ancient writers who mention Scandinavia are Ptolemy, Jordanes, and Procopius.

(*See further SCANDINAVIAN ARCHAEOLOGY.*)

**2. Swedish Expansion and the Viking Era, from A.D. 400.**—At the beginning of this period a number of independent tribes were settled in what is now Sweden, and their districts are still partly indicated by the present divisions of the country. The Swedes were centred in Uppland, around Uppsala. Farther south the Goths lived in the agricultural lands of Östergötland and Västergötland. The absence of historical sources makes it impossible to trace the long process by which the Swedes gradually subjugated the remaining areas. This historical event is reflected darkly in the Anglo-Saxon epic poem *Beowulf* (q.v.), which gives the earliest-known version of the word *sveorice*, *svearike*, *sveorige*.

(Sweden), and also in the Old Norse epic *Ynglingatal* contained in the *Heimskringla* of Snorri Sturluson (see ICELANDIC LITERATURE: Snorri Sturluson).

As a result of Arab expansion in the Mediterranean area in the 8th and 9th centuries, the trade routes along the Russian rivers to the Baltic Sea acquired enhanced importance. In the second half of the 9th century Swedish peasant chieftains secured a firm foothold in what is now eastern Russia and ruthlessly exploited the Slav population (see RUSSIAN HISTORY).

From strongholds, which included the river towns of Novgorod and Kiev, they controlled the trade routes along the Dnieper to the Black Sea and Constantinople and along the Volga to the Caspian Sea and the East. Trade in slaves and furs was particularly lucrative, as the rich finds of Arab silver coins in Swedish soil demonstrate. Swedish Vikings also controlled trade across the Baltic; and it was for this activity that Birka, generally regarded as Sweden's oldest town, was founded (c. 800). Swedish Vikings overran (c. 900) the important Danish trading settlement of Hedeby, and they took some part in raids against Western Europe. (See further VIKING.) But from the 10th century control of the Russian market began to slip from Swedish hands into those of Frisian, German, and Gotland merchants.

#### B. THE EARLY MIDDLE AGES

From about the 9th century, Sweden gradually became incorporated in the sphere of Western European culture. This is epitomized by the spread of Christianity there. A few Frankish missionaries had worked in Sweden for short periods as early as the 9th century, but no systematic evangelization took place until the 11th century. The new religion gained its first foothold in the Västergötland area, where King Olaf Skötkonung (d. c. 1022) was baptized. Olaf and his immediate successors, his sons Anund Jakob and Emund, and Emund's son-in-law Stenkil, had to fight against the adherents of the old heathenism, who had their main centre in Uppland, the famous temple at Uppsala (q.v.) being the chief religious shrine. In the succeeding reigns the struggle between adherents of the two faiths was intensified. The new cult steadily gained ground, nevertheless; some dioceses had come into existence by 1120, and under King Sverker (c. 1130–56) Cistercian monks were introduced. The establishment of Uppsala as an archbishopric in 1164 marked the final victory of Christianity, although Sweden was not formally constituted a province of the universal church until 1248. From 1210 onward the kings sought coronation at the hands of the church.

Royal power in Sweden, however, was still very weak in the early 13th century. The various territories remained largely independent, associated only in the form of a union under a common king. The king, after election by the Swedes, had to make an *eriksgata* (royal progress) through the central provinces to receive the homage of free men and their acclamation in the local assemblies (*ting*). The provinces were divided into smaller areas, *härads* (hundreds); these again were divided into parishes and towns. Each province had its own laws, mainly written down in the 13th or early 14th centuries, which perpetuated an archaic legal system.

At the close (c. 1050) of the Viking period the nobles were living as territorial lords on their own estates. But as church influence gradually destroyed slavery as an institution, the estates grew less remunerative and smallholdings were therefore leased to free or freed peasants. This led to much new cultivation. Meanwhile Swedish mining, centred round Västmanland and Dalarna, increased in importance, while a network of towns sprang up

REFO TO FROM RAPHO GUILLEMETTE  
SIXTH-CENTURY BURIAL MOUNDS ON  
THE SITE OF OLD UPSALA

in the 13th century, very largely inhabited by German merchants.

During the first two centuries of Christianity, the political centre was the Götaland area. From this region came two dynasties, which from 1130 to 1249 alternated on the throne. One, associated with Östergötland, was founded by King Sverker; the other, from Västergötland, was descended from St. Eric (reigned c. 1160), whose historical role was obscure and insignificant but who after his death came to be regarded as Sweden's national saint. At this time the Valdemar kings of Denmark and the Danish nobility frequently intervened in Swedish dynastic feuds.

From the 12th century onward, the highest office of state in Sweden was that of *jarl* (earl). The *jarl*, an official in many ways comparable with the Frankish mayor of the palace (q.v.), was the leader of the traditional levy of armed men and ships (*leding*). His power could often rival that of the king, and he was usually supported by the nobles. An aristocratic party, the Folkungar, developed and opposed the crown fairly successfully throughout the 13th century. At about the same time the practice of the king's consulting his leading subjects brought about the formation of the Council of State.

Despite their internal struggles the Swedes retained sufficient energy, using the *leding* as an important weapon, to expand eastward toward the old trade routes originally exploited by the Vikings. Desire for conquest was combined with Christian missionary zeal and "crusades" were aimed at the Finns, Estonians, and Russians. The southwestern parts of Finland were subjugated no later than the mid-13th century, part of Karelia in about 1300, and the city of Vyborg was established as a trading centre and military base. The island of Gotland was also incorporated in the kingdom of Sweden. But of modern Sweden, Skåne (Scania), Blekinge, and Halland still belonged to Denmark and Bohuslän, Härjedalen, and Jämtland to Norway.

#### C. THE LATER MIDDLE AGES

**1. Birger Jarl and His Successors to 1319.**—The dynasty of St. Eric came to an end with the death of Eric Ericsson (1222–49); the new elected king was his nephew Valdemar (1250–75), a minor whose father Birger, *jarl* since 1248, ruled until his death in 1266. Birger Jarl (q.v.) fought the aristocratic Folkung Party, severely defeating it in 1248 and 1251. He supported the church and enhanced the power of the crown by issuing the first Swedish national laws ordering the maintenance of peace in the church, the home, the *Ting* (assembly), and for women. Daughters as well as sons were granted inheritance rights. By granting privileges he encouraged the trade of the Lübeck merchants in Sweden.

Birger Jarl's policy was continued by his second son, Magnus Ladulås (1275–90), who after a revolt against his brother Valdemar was hailed as king. Magnus further strengthened his authority and reorganized the taxation system, replacing the obligation to take part in the *leding* by fixed dues. He granted the church considerable freedom from taxation, however. By the Ordinance of Alsnö in 1280, those who performed military service were declared exempt from taxation; thus a privileged aristocracy was established, from which an army of knights could be raised. Collaboration between king and nobility was increased by the establishment of new offices of state, the *drots*, *marsk*, and *kansler*, corresponding roughly to those of lord high steward, marshal or constable, and chancellor. The office of *jarl* was now suppressed. The state council, of some importance since c. 1220, was in about 1280 extended and given a permanent status. Magnus' reign was characterized by closer relations with Denmark, expressed by the marriages of his daughter Ingeborg with King Eric VI Menved and of his son Birger with Eric's sister Märta.

During the minority of Birger Magnusson (1290–1318), the government was in the hands of the *marsk* Torgils Knutsson, who furthered the interests of the nobility at the expense of the church. He also extended Swedish power in Finland. On assuming personal power, Birger at first sought the *marsk*'s support against his two rebellious brothers, the dukes Eric and Valdemar. But the three brothers were reconciled in 1305, and Birger then had Torgils executed. However, the quarrel broke out afresh, and Birger was

taken prisoner (1306) by the dukes. He was released on the intervention of Eric Menved, and in 1310 the country was partitioned among the three brothers, Duke Eric using a Norwegian marriage alliance with the daughter and heiress of Haakon V to combine western Sweden with adjoining portions of Denmark and Norway. But in 1317 King Birger managed to have his brothers seized and thrown into prison, where they died. The aristocracy now rose to avenge the dukes; Birger was driven into exile in Denmark, and in 1319 Duke Eric's three-year-old son Magnus (*q.v.*) was elected successor to the throne. He inherited the crown of Norway from his grandfather Haakon the same year. A regency was set up under the *drots* Mats Kettilmundsson.

**2. Magnus II Ericsson to the Scandinavian Union.**—The succeeding decades were peaceful, a time of cultural and economic progress. A colourful figure of the period was St. Bridget (*q.v.*; Birgitta). By a treaty (1323) with Novgorod, the frontier between Russia and Sweden through Finland was defined. Within Sweden itself the establishment (1347) of a common law, superseding the old provincial laws, did much to integrate the various provinces. However, the elective nature of the monarchy and the king's obligation to consult his council were reaffirmed. Although feudalism, as found in France and Germany, had never existed in Sweden, some characteristics of the system of chivalry appeared there in the 14th century. Swedish trade became dominated by the Hanseatic League (*q.v.*), which entirely controlled the export of iron, copper, hides, furs, and butter; in the towns the most powerful burghers were German merchants.

In the latter years of his reign King Magnus II (VI of Norway) Ericsson encountered increasing opposition. His taxation policy antagonized the church and the aristocracy, and unsuccessful wars with Russia and Denmark contributed to the discontent. The Danish king Valdemar IV seized the opportunity to recapture (1360) Skåne and Blekinge, which Sweden had won in 1332, and took Gotland (1361). Magnus made peace with King Valdemar (1363), marrying his son, Haakon, to Valdemar's daughter and heiress, Margaret. Haakon had since 1355 been king of Norway and his father's co-regent in Sweden. The Swedish nobles, alarmed at the prospect of Haakon's succession, rebelled; they called in Albert (Albrecht) of Mecklenburg, a nephew of King Magnus, who fought Magnus and Haakon and finally became king in 1364. He was forced, however, to buy aid by making substantial concessions to the aristocracy (1371). Sweden's real master at this time was its greatest and richest landowner, the *drots* Bo Jonsson Grip. After Bo Jonsson's death (1386) Albert tried to assert his authority, but the Swedish nobles now made an agreement with Margaret, who, since the death of her father, Valdemar (1375), and her husband, Haakon (1380), had been regent in Denmark and Norway. Albert was deposed (1389) and she became regent in Sweden also. There, by skilfully playing off different groups and interests, she strengthened the royal power and recovered many recently alienated crown estates. Tax reforms were introduced, and bailiffs subordinate to the regent were appointed to administer finances. Margaret's only son had died in childhood, so she designated as her successor Eric (*q.v.*) of Pomerania, her great-nephew. At a meeting of nobles from all over Scandinavia at Kalmar in June 1397, Eric was crowned king of the three kingdoms.

**3. Eric of Pomerania to Christian II.**—After Margaret's death (1412) Eric of Pomerania strove to weld the Scandinavian kingdoms into a centralized absolute monarchy and to extend the frontiers of Denmark southward. The former aim antagonized the Swedish Council of State, the latter led to a protracted war with Holstein. Eric's coinage policy and tax reorganizations aroused discontent among the peasants, and when the Hanseatic League, as part of the Holstein war, blockaded Eric's states, export of iron and copper was stopped. This outraged the miners of Västmanland and Dalarna, and a mine owner of the petty nobility, Engelbrekt Engelbrektsson (d. 1436), led a popular rebellion in 1434. Opposition was to royal absolutism rather than to the Scandinavian union. After some years' fighting Eric was deposed (1439 in Denmark and Sweden; 1442 in Norway). The council, led by the ambitious *marsh* Karl Knutsson Bonde, seized power, retaining its substance even after the election of a new union king,

Christopher of Bavaria (1441–48). The council favoured aristocratic pretensions, but the part played by the common people in these struggles was constitutionally significant, for representatives of the peasantry began to attend state meetings. In this way the Swedish *Riksdag* (Parliament) came into being, with its four estates of nobles, clergy, burghers, and peasants.

On Christopher's death Karl Knutsson (*see* CHARLES VIII) was elected king of Sweden while Christian I (*q.v.*) of Oldenburg was hailed king in Denmark. In 1457 Charles was exiled by a faction of nobles under Archbishop Jöns Bengtsson Oxenstierna and Christian was elected king of Sweden (1457). A revolt against Christian breaking out (1464), Charles returned but held the crown for only six months, and again, with the help of the brothers Axelsson Tott, from 1467 until his death in 1470. Sten Sture the Elder (*see* STURE), a kinsman of the powerful Axelssons, was made state administrator in 1471. Christian was finally defeated at the battle of Brunkeberg (near Stockholm) in 1471. But despite Sten Sture's careful financial policy and the broad support he commanded from miners, burghers, and peasants, the Council of State desired to reestablish the union and hailed Christian's son Hans (Johannes) as king (*see* JOHN [Hans]) in 1497. They then found John's policies distasteful, and a revolt in 1501 led to the reappointment of Sten Sture as regent. Sten died in 1503 and was succeeded in office first by Svante (Nilsson) Sture (d. 1512) and then by Svante's son Sten Sture the Younger. Sten sought to establish a virtual dictatorship, but he was wounded in battle (1520) fighting against the Danish king Christian II (*q.v.*) and died soon afterward. Christian, crowned king of Sweden the following autumn, finally destroyed Sture's party in the so-called Stockholm blood bath in November 1520.

(L. T. N.)

#### D. THE EARLY VASA KINGS, 1520–1611

**1. Gustavus I Vasa (1523–60) and the Reformation.**—The defeat of Sten Sture's party and the massacre of so many of its leaders left Gustavus I (*q.v.*) Vasa, who had fought in Sture's army, as the only prominent opponent of Christian II. His ability to continue the struggle, however, depended very largely on the aid of Lübeck, which feared Christian's plans for economic hegemony of the Baltic. With Lübeck's aid—perhaps on Lübeck's insistence—Gustavus was chosen king at Strängnäs in June 1523. He was forced to concede far-reaching economic privileges which gave Lübeck a dominant position in the Swedish economy. But he was not content to be Lübeck's puppet, and he resisted its demands throughout his reign. At first, however, he had no option but to extract money from his subjects, to meet Lübeck's demands: the resulting financial crisis led directly to the Reformation in Sweden.

The medieval Swedish church had escaped the Hussite or Wycliffite heresies. It had grown comparatively wealthy through tax exemptions, donations, and trade, and it probably owned something like a quarter of the land. But it was engaged in a costly struggle with the nobility for tax-exempted land; and a connection, through its leaders, with the higher aristocracy, which had supported the union, led to clashes with the Sture party. For the Stures had aimed increasingly at a strong monarchy, free of the constitutional checks which the aristocracy had traditionally supplied, and effectively in control of a national church. Their view that the church should contribute when the country was in need was not far removed from the notion that the wealth of the church is the wealth of the people, which became accepted doctrine when Lutheranism reached Sweden in the early 1520s. The pressure of Lübeck, the jealousy of the nobility, the traditional Sture policy that the king ought not to suffer "two lords in one land," and finally the refusal of the papacy to abandon clerics (such as Archbishop Gustavus Trolle) who had become politically impossible as partisans of Denmark—these were the factors that combined to produce the Reformation. The plunder of the church and the bidding of the nobility with church lands began after the Diet of Västerås in 1527 and continued throughout the reign of Gustavus. However, the spoils of the church made the crown, for the first time, really wealthy, and so gave strength and stability to monarchy and country.

Doctrinally the Swedish Reformation was Lutheran. Its most conspicuous leaders were the brothers Olaus and Laurentius Petri (*q.v.*), each of whom had great literary gifts; their writing did much to standardize the modern language of their country, as Luther's did in Germany. Except in Stockholm, Protestantism at first made slow progress. It was a religion to which the king had recourse for national ends, but not for a generation was it a national religion. Revolts in Västergötland (1529) and Dalarna (1531), and the great revolt of Nils Dacke in Småland (1542-43), bore witness to the unpopularity of the new services. Indeed, the decisive initial step at Västerås in 1527 had been forced through by the king only by a threat to abdicate. As consequences of this situation, considerable elements of the old faith were allowed to remain, there was a wide toleration of opinion, and doctrinally the position was kept remarkably vague. Gustavus himself was concerned only with the royal supremacy, and this led him, at the end of the 1530s, to a sharp quarrel with the reformers and an attempt to treat the church as a mere department of state.

The foreign policy of the reign was a reflection of these internal problems. Sweden was temporarily secure from any attempt to revive the union with Denmark, for Christian II had been driven from the Danish throne (1523) by his uncle, Frederick I, and until his death (1559) Frederick and his successor, Christian III, were linked to Gustavus by common fear of his restoration. This was seen clearly in the so-called Counts' War (1534-36), when Sweden and Denmark defeated an attempt by Lübeck and a coalition of German princes to restore Christian II, Gustavus taking the opportunity to break free from Lübeck's control. It appeared again in the Swedish-Danish alliance of Brömsebro (1541), which linked Gustavus at second hand to the League of Schmalkalden (his efforts to join the League itself having failed, but Denmark being a member) and brought Sweden into the French camp. But the country's situation prescribed caution in foreign affairs, and after 1535 Gustavus' only adventure was a brief war with Muscovy (1554-57). Gustavus' avoidance of risk was justified by the situation of the country and by results. When he died in 1560 the monarchy was strong and rich; it had acquired a considerable navy and had begun (since 1544) to form that army of conscript militia-men which was to be the instrument of Sweden's later greatness. Above all, by the Succession Pact of 1544 Gustavus had obtained the assent of his estates to the transformation of Sweden from an elective to a hereditary monarchy. On his death his eldest son, Eric XIV (*q.v.*), at once succeeded him.

**2. Eric XIV (1560-68), John III (1568-92), Sigismund (1592-99), and Charles IX (1607-11).**—On Eric's accession the latent struggle between the principles of popular despotism and aristocratic constitutionalism was renewed. It was heightened by the difficulties provoked by Gustavus' will, in which he had bequeathed to his younger sons large duchies, semi-independent of the crown. John, the eldest of Eric's half-brothers, had been made duke of Finland, where he attempted to carry on a private foreign policy at variance with that of the crown. Eric took strong measures. By the Articles of Arboga (1561) he forced a drastic curtailment in the franchises of the royal dukes, and in 1562 he imprisoned John. A specially constituted High Court became an instrument of tyranny against Eric's supposed enemies and particularly against members of the higher nobility.

Arbitrary, despotic, and proud, Eric had a high idea of his dignity. He attributed his failure to bring off a satisfactory foreign marriage to the ill will of his noble emissaries, and so intensified his vendetta against the aristocracy. His marriage with Karin Månsdotter, a girl of humble origin who had been his mistress, was at once a calculated insult to the aristocracy and a deliberate assertion of sovereign power. He took care, however, to cultivate the *Riksdag*, and when possible got it to endorse his actions; had he reigned longer, he might well have developed a real parliamentary despotism. In 1567, however, a sudden crisis of the morbid suspiciousness to which he was prone led him to murder Nils Sture and to order the slaughter of two other members of the influential Sture family. The deed temporarily unhinged him. He released his brother John from prison (1567) and after some weeks resumed the conduct of government. But John, with

his younger brother Charles (later Charles IX), rose in revolt, deposed him, and in 1568 ascended the throne as John III (*q.v.*).

Eric's removal took place at a moment when Sweden was heavily engaged in war with Denmark and Poland. The collapse of the Livonian state ruled by the Knights of the Sword (a branch of the Teutonic Order), in the 1550s, had led to a scramble among their neighbours for the reversion to their territories. Eric, fearing that Denmark might make dangerous gains in this area, and hoping to secure control of the lucrative trade to Russia, had responded to an appeal from Reval (now Tallinn) for protection. A Swedish force went to Estonia, and the first stone in the later Swedish empire was laid. Eric, realizing that he must choose between the friendship of Russia and that of Poland, opted for Russia. But John had made a Polish marriage and hoped for gains of his own in Livonia. At the same time, Frederick II of Denmark, who aspired to recreate the old Scandinavian union, declared war on Sweden; and Sigismund II Augustus of Poland shortly joined him.

The Seven Years' War of the North (1563-70), in spite of brilliant successes by the Swedish navy, imposed a heavy strain on the country, which was almost blockaded from access from Western Europe. By the Peace of Stettin (December 1570) Sweden ceded its Estonian lands and had to pay a heavy indemnity to Denmark. John III contrived to evade compliance with the former provision, and for most of his reign he carried on a long and ultimately successful struggle with Russia. By the Peace of Täysinä (1595) Sweden established its occupation of most of Estonia, including the ports of Narva and Reval.

Meanwhile John III had been embarking on a religious policy of his own, designed to pave the way for a general reconciliation between the Protestant world and Rome. The policy broke down on Rome's refusal to make the concessions he considered indispensable, but in any case it had provoked strong reactions in Sweden. The country was now solidly Lutheran, and the Swedish Church was adopting precise doctrinal positions in the face of the imminence of a Roman Catholic successor; for Sigismund, John's heir, had taken the religion of his Polish mother. In 1587 Sigismund was elected king of Poland (Sigismund III; *q.v.*), and soon proved himself an ardent champion of the Counter-Reformation. For Sweden the dynastic union with Poland had obvious advantages for foreign policy, and an absentee monarch might well allow the higher aristocracy to regain the position they had lost since 1523. But the prospect of a return to Rome was nowhere popular. The accession of Sigismund in 1592 therefore inaugurated a period of domestic disturbance in which the cause of Protestantism offered a rallying cry to those who opposed the king. Foremost among these was Charles (*see* CHARLES IX), youngest son of Gustavus I, brother of John III, and uncle of Sigismund.

Charles rallied the church round him at Uppsala in 1593 in a kind of national covenant to defend the Lutheran cause. At the same time he persuaded the aristocratic council to unite with him in opposing the king's attempt to rule Sweden from Poland. The union was only temporary, however, and the council was not prepared to follow Charles into more or less open rebellion against the lawful sovereign, who was crowned in February 1594. By 1597 the solid national front of 1593 was dissolving: the council's members were seeking refuge in Poland, and Charles, supported mainly by the lower orders of the *Riksdag*, had passed from constitutional opposition to revolution. In 1598 Sigismund went to Sweden for the second time (his first visit was 1593-94), but his army was defeated at Stångebro. He failed to carry out the terms then agreed upon and so in 1599 was deposed by the *Riksdag*. The next year, at Linköping, Charles executed four of his leading noble opponents. He did not at once call himself king, however, and his coronation was deferred till 1607 because he had some scruples about the rights of John III's younger son, John. But from 1604, when young John renounced his claim and the *Riksdag* agreed to the Succession Pact of Norrköping, the crown was effectively transferred to the younger Vasa line.

The deposition of Sigismund led to a dynastic feud which lasted for nearly 60 years and which became linked with the old rivalry for the control of Estonia and Livonia and also with the struggle to preserve the Protestantism of the north. At first Poland had

the advantage, and in 1605 Charles suffered at Kirkholm one of the most disastrous defeats of Swedish history. Thereafter, for some years, the duel was transferred to Russia, where Sigismund sought to establish himself or his son Wladyslaw as tsar (see *Russian History*). At the same time Charles's rash and provocative policy in the Baltic and the Arctic aroused the enmity of Denmark, where the young and ambitious king Christian IV hoped to re-establish the old Scandinavian union. When Charles died in 1611 he thus bequeathed to his son, Gustavus II (*q.v.*) Adolphus, wars with Denmark and Poland and in Russia. If the prospect in the field of foreign affairs was gloomy, the situation at home was no better. Charles's rule had alarmed and alienated the nobility; the country was exhausted by long wars; methods of administration were outdated, and the army and navy required drastic reform.

#### E. THE AGE OF SWEDISH GREATNESS, 1611-1718

**1. Gustavus II Adolphus (1611-32).**—On the accession of Gustavus Adolphus the nobility, led by Axel Gustafsson Oxenstierna (*q.v.*), extorted from the young king (who was not yet 17), as the price of his immediate assumption of government, a charter which was intended to guarantee the country against the excesses of Charles's parliamentary despotism and which might well have led to a long struggle between monarchy and aristocracy. That it did not do so was due to the restraint and wisdom of Gustavus and of Oxenstierna and to the reciprocal respect and affection which developed between them. Oxenstierna, created chancellor in 1612, retained that office, and the king's confidence, for the whole of the reign. Together they carried through a remarkable series of measures which make Gustavus' reign one of the great reforming epochs of Swedish history and which did much to make possible the emergence of Sweden for a time as a great power. These included reforms of the central and local government and of the judiciary, the systematic development and exploitation of the mineral resources of the country, the building up of an adequate armaments industry, the encouragement of foreign investment, the recruitment of foreign artisans and entrepreneurs, and the beginnings of the conversion of an increasing proportion of the old revenues in kind into revenues in cash. At the same time the navy was thoroughly overhauled and the army was trained in a new style of tactics which was to carry all before it on the battlefields of Germany. The reign was also a period of important educational progress, especially in regard to the expansion and endowment of the University of Uppsala.

In foreign affairs, although Gustavus was forced to accept a hard peace with Denmark in 1613, the first two decades of the reign saw the gradual emergence of Sweden, rather than Denmark, as the stronger Scandinavian power. The war in Russia was brought to a successful conclusion at Stolbova in 1617 by a peace which gave Sweden continuous territorial connection between Finland and Estonia and shut Russia off from access to the Baltic. The war with Poland went in Sweden's favour too. In 1629 Gustavus was able to conclude a six years' truce at Altmärk which left him in possession of most of Livonia and permitted him to finance his coming war in Germany from the tolls at Prussian harbours.

Thus by 1630 Sweden had acquired a considerable Baltic empire and would have been in a strong position to settle old scores with Denmark. But the danger to Protestantism in Germany had provoked a strong sympathetic response in Sweden, and, further, Gustavus feared that an imperialist occupation of north Germany might be the prelude to an attempt to restore Sigismund to the Swedish throne. The expedition he took to Germany in 1630 (see *THIRTY YEARS' WAR*) was thus designed both to defend the cause of Protestantism and to protect Sweden's interests. Its brilliant success not merely changed the history of Germany but profoundly affected the history of Sweden.

**2. Queen Christina (1644-54).**—The death of Gustavus Adolphus at the Battle of Lützen in November 1632 produced a crisis. His daughter Christina (*q.v.*), still a minor, was recognized as queen, and the regency was undertaken first by a Council of the Realm (*Riksråd*) and subsequently by five senators, in accordance with the *Form of Government* which, drawn up by Oxen-

stierna and approved by Gustavus shortly before his death, was approved by the *Riksdag* in 1634. By this constitution the five senators were also to be the leaders or presidents of five colleges or committees formed from a total council of 25, which was responsible for central government. Local government was to be in the hands of provincial governors.

During Christina's minority the government was controlled by Oxenstierna, who as chancellor was one of the five senators. He continued Gustavus' policy both at home and abroad. Although the treaty made with France in 1631 was renewed in April 1633, Sweden was severely defeated (autumn 1634) by imperial forces under Spanish command and its prestige was much damaged. As a result, Saxony made peace with the emperor in 1635 and Brandenburg followed in 1636; both then declared war on Sweden. Field Marshal Johan Banér (*q.v.*), however, won victories for Sweden at Wittstock (1636) and Chemnitz (1639). That won by Banér's successor, Lennart Torstensson (*q.v.*), was so decisive that Oxenstierna could now deploy the Swedish army against another enemy, Denmark. Torstensson invaded Jutland in 1643. The Danish king Christian IV was obliged to make peace at Brömsebro (Christianopel) in 1645, ceding to Sweden Jämtland and Härjedalen (Norway), Halland (Denmark), and the islands of Gotland and Ösel, and exempting from the Öresund tolls goods destined for Sweden and the Baltic provinces.

Christina had begun her personal rule in 1644. At first she clashed with Oxenstierna and was personally responsible for moves which contributed to the Peace of Westphalia, ending the Thirty Years' War in 1648. By this treaty Sweden acquired in Germany parts of Pomerania, the Baltic port of Wismar, the archbishopric of Bremen and the bishopric of Verden, and prize money for the Swedish soldiers. After 1650, however, she worked more closely with Oxenstierna. Although Christina encouraged trade and industry, she could not solve the desperate financial problems caused by prolonged war and aggravated by her own extravagance. In 1654 she became a Catholic and abdicated, having in 1649 declared as her successor her cousin Charles Gustavus (Charles X).

**3. Charles X Gustavus (1654-60).**—On the accession in 1654 of Charles X (*q.v.*) the costs of the court were cut down, and in the *Riksdag* of 1655 he imposed the so-called Reduction. By this law the nobles were obliged to restore to the crown certain endowed estates and a quarter of those granted since 1633. In future certain estates were to be given only temporarily, automatically reverting to the crown on the accession of a new monarch. The law was at once applied but ceased to operate during the years of war which followed.

Charles X's short reign was one of almost continual warfare, and Charles himself was a skilful general. The truce of Altmärk, made with Poland in 1629, had been renewed in 1635, but because the Russians showed signs of attacking Poland, and therefore possibly encircling the trans-Baltic possessions of Sweden, Charles and the *Riksdag* decided to act first. He took Warsaw and Cracow (1655) and the Polish king, John Casimir, fled. But the successful defense of the monastery of Czystochowa late in 1655 revived Polish hopes. John Casimir returned to Poland, and two years of fruitless fighting ensued. In 1656 the Russians began an alliance upon the Swedish Baltic provinces and Charles made an alliance with Frederick William, elector of Brandenburg. The emperor joined Sweden's enemies in the same year and Holland and Denmark followed. Brandenburg now deserted Sweden.

Fortunately for Sweden, these numerous enemies did not cooperate. Charles turned resolutely on Denmark, took Jutland, and led his troops over the ice to Fyn and then across the other islands to Sjælland. Denmark was forced to make peace in February 1658 at Roskilde, ceding the Skåne provinces, the island of Bornholm, and Trondheim and Bohuslän in Norway. Both kingdoms were to cooperate to keep foreign fleets out of the Baltic. However, Dutch influence in Denmark remained strong, and Charles dared not turn to deal with problems in the east while there was any danger of the Dutch inciting Denmark to attack him. He therefore himself renewed the war in August 1658. But the Danes now put up a spirited resistance, and an attack on Copenhagen was repulsed (February 1659). Trondheim and Bornholm resisted

Swedish control. In this difficult situation, a *Riksdag* was summoned to Göteborg early in 1660, but Charles died (Feb. 13) during its session. (S. I. O.)

4. **The Regency (1660-75).**—Charles X was succeeded by his son Charles XI (*q.v.*), a child of four, and the antiroyalist leaders of the nobility therefore decided to reverse the trends of recent internal policy. On his death bed Charles X had tried to safeguard the power of the crown, so intimately bound up with the Reduction, by naming a regency pledged to carry on his reform plans. The antiroyalist party, however, prevailed upon the Estates to declare Charles X's will null and void, since it had been made without the Estates' consent. By making subsequent changes in the composition of the regency and the council, the high nobility secured control of the government. The *Riksdag* charged the new government with the continuation of the Reduction, but the qualifying clause "to be pursued with justice and moderation," inserted by the efforts of the nobility, was interpreted in such a way that the resumption of alienated crown land came to a virtual standstill.

The Estates also charged the government with procuring peace. With French help the status quo of 1648 was restored at the Peace of Oliva (April 1660) with the emperor Leopold I, Brandenburg, and Poland. Because of the critical illness of John Casimir of Poland, Sweden obtained two important advantages: the queen of Poland, anxious to gain support for the election of one of John Casimir's sons, agreed to renounce "eternally" both the Polish Vasa claim to the Swedish crown and the Polish claim on Swedish Livonia. At the Peace of Copenhagen (May 1660) Sweden restored to Denmark-Norway the province of Trondheim, with its access to the Atlantic, and the island of Bornholm. A third gain from the Roskilde Treaty of 1658 was also relinquished: the clause forbidding foreign navies to enter the Baltic was rescinded at the demand of England and the United Provinces. The Dutch, having supported Denmark-Norway, had already (November 1659) gained equality with Swedish subjects in respect of trade with the Swedish Baltic provinces. A double blow was thus struck at Sweden's hopes of dominating the Baltic politically and at its plans for commercial and maritime competition with the Dutch. The peace treaties of Oliva and Copenhagen, however, strengthened Sweden's hand in negotiations with Russia. In the Peace of Kardis (June 1661), Russia again recognized Swedish possession of Karelia, Ingria (Ingermanland), and Estonia.

Sweden now regarded itself as a satiated power; aggressive or preventive wars were no longer visualized as practical politics, and Sweden never exceeded these frontiers. Its population was now a little over 2,000,000, rising by the year 1700 to nearly 3,000,000, half of whom lived outside Sweden-Finland. The cohesion in the Swedish Empire was provided by Swedish political and economic policy and by Swedish civil and military administration.

What Swedish historians have labeled "the problem of the peace" remained: how to finance an army and a navy and erect fortifications to safeguard its great power position. On this problem there was no agreement. The non-noble Estates and many of the nobility (mainly of the lower and bureaucratic ranks) favoured a policy whereby the king should maintain the necessary forces by a resumption of alienated land more far-reaching than the one-quarter Reduction envisaged under Charles X, both in Sweden-Finland and in the Swedish Empire. The higher nobility, however, by securing control at the accession of Charles XI, were able to impose their solution: reliance on foreign subsidies, mainly from France, until expansion of trade and shipping (particularly the attempts at linking Russian and Polish trade with Europe via Swedish ports) should produce sufficient income in tolls and dues to pay for defense.

A distinction used to be drawn between the "pro-French" and "anti-French" regents and councilors of Sweden to explain changes in foreign policy. Modern historians, however, have focused attention more on the common aim of these men: a balancing policy between the European powers, perpetuating the peace of 1648 but allowing Sweden by its services as an armed mediator to reap advantages from existing tension between France and the Habsburg bloc, on the one hand, and between the two maritime powers, En-

gland and the United Provinces, on the other. Until 1675 the balancing policy was on the whole successful and brought various gains, chief of which was the formal installation (1664) of Sweden in the Holy Roman Empire (denied since 1648 by successive emperors) following a period of collaboration with the Habsburgs, both Spanish and Austrians, and with Brandenburg.

5. **The War of 1675.**—Charles XI was declared of age in 1672, but in reality the regents remained in control. Under the regency the Swedish Bank had been established in 1668 and the University of Lund founded in the same year. But the armed forces had been neglected in a period of great international tension; and, moreover, the regency had underestimated the danger of involving Sweden in a war not essential for its own defense when they signed a subsidy treaty with France in 1669. By the treaty Sweden undertook to prevent the emperor and other princes of the Holy Roman Empire from assisting the Dutch during the attack which Louis XIV and England were planning on the United Provinces. At most the Swedish government visualized its troops acting as an auxiliary corps while Sweden remained neutral. The real attraction of the treaty was embodied in secret articles; Sweden was by Louis XIV accorded that position of arbiter in the empire which it had long desired, and thought itself to have been made the arbiter also in western Europe by Louis's guarantee of the integrity of the southern Netherlands and his promise "not to ruin the Dutch."

Swedish calculations miscarried. After attacking the United Provinces in 1672 (*see* DUTCH WARS) Louis outmaneuvered the Swedish regents; by withholding money he was able to dictate the movements of the Swedish troops in Germany. The crossing of the Brandenburg frontier by Swedish troops from Swedish Pomerania in 1674 led to the Swedish defeat at Fehrbellin in June 1675 (partly explained by Sweden's desire to avoid a full-scale war), and Brandenburg and its allies, the United Provinces and the emperor, declared war on Sweden. This encouraged Denmark-Norway to invade Skåne.

The war for Skåne (1675-79) proved a tough one. The regents and most of the councilors were discredited by the poor state of the army and navy, and Charles XI himself and new men, prominent among them Johan Gyllenstierna (*q.v.*), took over the leadership both in the armed forces and in the administration. The Swedish victory at Lund (December 1676) marked a turning point, and by 1678 the Danish-Norwegian forces had been expelled and the guerrilla fighters of Skåne subdued. Peace was made at the Treaty of Lund (September 1679), and Denmark gave up hopes of reconquering Skåne. A joint future stand was agreed upon against Dutch commercial predominance in the Baltic, and the alliance was sealed by the marriage (arranged before the war) of Charles XI with Ulrika Eleonora, sister of Christian V of Denmark-Norway. Historians have often interpreted this treaty as an "alliance of equal partners," but recent research shows that Gyllenstierna and Charles envisaged Sweden as the dominant force.

During the war Sweden's German possessions had been overrun by the armies of the emperor, the elector of Brandenburg, and Denmark. Thanks to Louis XIV's diplomatic efforts, in the treaties of Nijmegen (*q.v.*; February 1679), St. Germain (June 1679), and Fontainebleau (September 1679), these were all restored except a small strip of Pomerania ceded to Brandenburg. However, the manner in which these treaties were concluded, with no consultation with the Swedish government, offended Charles XI. The Swedes also regretted that the Dutch were not deprived of their commercial advantages gained from Sweden in the 1650s.

6. **The Personal Rule of Charles XI (1679-97).**—The king and his new advisers were now determined to make Sweden independent of foreign subsidy treaties. "Reduction," the resumption of alienated crown land, or of land equivalent in value in respect of yearly income, was systematically pursued and continually widened from the one-quarter demanded by Charles X. At the end of the reign the crown, from having been in possession of less than one percent of all land in Sweden-Finland in 1679, once more held, as in the first quarter of the 16th century, over 30%. In the trans-Baltic provinces all land alienated during the period of Swedish rule had been resumed and the resumption of land alien-

ated before that time had begun. Out of the total state income a fixed budget was set up which continued until 1809. This permitted a force of 25,000 hired troops for garrison duties, the payment of a civil administration embracing also church and education, and finally the maintenance of a national army of 40,000 men and a navy built to compete with the strength of Denmark-Norway and based at the new southern port, Karlskrona. During the work of reorganization, absolutism was introduced into Sweden and the Swedish Baltic provinces as a means to force through reform and to safeguard the crown against any future reversal of its achievements. In Sweden's German provinces, absolutism could not become the form of government since the constitutions of these possessions had been guaranteed by the Treaties of Westphalia (1648).

Charles XI's reign saw the encouragement of the arts, the growth of the capital, Stockholm, and the full incorporation into Sweden-Finland of the Danish and Norwegian provinces conquered under Charles X; the war of 1700-21 (see below) produced no guerrilla fighting in Skåne. In foreign affairs Charles XI and his advisers continued the "balancing policy." Sweden at first cooperated with the Dutch and the emperor (Treaty of The Hague, 1681) against Louis XIV, but the personal union of England and the United Provinces under William III in 1688 was considered as serious a threat to the balance of power as French expansion. For this reason Sweden remained uncommitted during the War of the Grand Alliance (*q.v.*; 1689-97), though Charles XI supplied the emperor with his quota of troops in respect of his duties as an imperial prince. An additional motive for neutrality was Sweden's desire to profit from the war in building up its commerce and shipping; its merchant fleet rose to 730 ships, the highest point ever reached in the great power period. Charles XI was made mediator at the Congress of Rijswijk (1697), but this remained an empty honour, Sweden gaining neither prestige nor advantage from its neutrality. During the war Sweden and Denmark-Norway intermittently cooperated in a policy of "armed neutrality" to protect common maritime and commercial interests, but at the same time Charles XI and his advisers, including Count Bengt Oxenstierna (*q.v.*), contained Denmark from the south by a vigorous support of the duke of Holstein-Gottorp and the latter's possessions and rights in the ducal parts of Schleswig and Holstein. Before Charles XI's death (April 1697) he arranged for the dynastic ties with the house of Holstein-Gottorp to be continued by a marriage between his elder daughter, Hedvig Sophia, and his nephew Frederick Adolphus, duke of Holstein-Gottorp since 1694.

**7. Charles XII (1697-1718).**—Holstein-Gottorp issues loomed large in the early days of the reign of Charles XI's young son, Charles XII (*q.v.*). On Charles XI's death, Christian V of Denmark-Norway invaded the ducal parts of Schleswig-Holstein and razed the fortifications which Frederick Adolphus, with Swedish consent and help, was building there. The duke fled to Sweden. In an attempt to break Sweden's connection with Holstein-Gottorp, Christian V proposed to the regents of Charles XII a Danish dynastic alliance by the marriage of his daughter Sophia to Charles XII. The regents, however, had learned of Danish negotiations with Prussia and Russia for an anti-Swedish alliance, and the marriage offer was shelved. Charles XII, declared of age in November 1697, continued along traditional pro-Holstein-Gottorp lines; the marriage between Frederick Adolphus and Hedvig Sophia took place in 1698, and the Swedish army in Germany was reinforced to permit the ducal fortifications to be reerected. This Swedish defiance of Denmark-Norway accelerated Danish negotiations for an attack on Sweden. Those with Frederick Augustus I of Saxony (which the Swedish intelligence service did not discover) were completed in 1698 by Christian V and renewed in 1699 by his successor, Frederick IV; those with Tsar Peter of Russia bore fruit by 1700, and in February 1700 war broke out (see NORTHERN WAR).

Denmark-Norway and its allies had expected the Swedish nobility to rise against absolutism and the Reduction once Charles XII was attacked; but they remained loyal. The reorganized army and the newly built navy proved their worth, as did the young king himself, and the anti-Swedish coalition, reinforced by Prussia

and Hanover in 1714, was kept at bay till Charles XII's death in November 1718 in spite of setbacks between 1709 and 1715.

Sweden, however, by 1718 was tired of absolutism and of war. The plague of 1710-11 (which cost many more lives than the war) and the loss of both civilian administrators and officers, imprisoned in Russia since 1709, had their effect. The loss of the Swedish Empire and the Russian occupation of Finland meant more. But in the last instance the intense dislike of the innovations in the financial and bureaucratic machinery which Charles XII had introduced in his attempt to mobilize the country's resources for the war effort unseated absolutism. Preparations for its overthrow had been made in the event of the king's death by those who resented the attempts at cabinet government, often with foreign helpers, and who contrasted it unfavourably with the "Swedish" bureaucratic absolutism of Charles XI's days.

#### F. THE GROWTH OF PARLIAMENTARY GOVERNMENT, 1718-1772

**1. Ulrika Eleonora (1718-20).**—Charles never married, and the absence of a direct heir facilitated the revolution, since those who favoured a return to constitutional government could play off two possible claimants, Charles XII's only surviving sister, Ulrika Eleonora, wife of Frederick of Hesse-Kassel, and the late king's nephew, Charles Frederick, duke of Holstein-Gottorp (the son of Hedvig Sophia and Frederick Adolphus). Ulrika Eleonora (*q.v.*) let herself be proclaimed hereditary ruler on the news of her brother's death; but the revolutionary forces in army and administration prevailed upon her by January 1719 to accept the crown from the Estates as an elected queen. She was crowned in May only after having sworn to honour a constitution to be formulated by the Estates. Even so, she proved to be too steeped in the absolutist tradition, and as her personal desire was for a joint rule with her husband this was cleverly used to engineer her abdication (1720) in favour of her husband, who became Frederick I (*q.v.*).

**2. Frederick I (1720-51).**—The crown, already weakened by the fact that Frederick I was an elected king, and circumscribed by the constitution of 1720, in which the king possessed only two votes in the council and could thus be outvoted, lost further prestige by the setbacks to Frederick's peace plans. European-wide support against Tsar Peter—which George I, elector of Hanover and king of England, had promised when Frederick agreed to cede Bremen and Verden to Hanover (November 1719) and most of Swedish Pomerania to Prussia (January 1720)—failed to materialize. Sweden was therefore forced to make peace with Russia at the Treaty of Nystad (Sept. 10, 1721), ceding Ingria, Estonia, and Livonia and also part of southeastern Finland. The crown mattered little in the ensuing struggles for power in Sweden, in which the bureaucratic and service nobility of Charles XI and Charles XII's reigns limited the privileges of the high nobility, and the Estates and the committees of the Estates (prominent among them the "secret committee") made inroads on the power of the council, still the preserve of the higher nobility. Throughout the reign there was a development toward parliamentary government with its demand that councilors should change according to success or failure of the parties which developed in the Estates. These parties were differentiated by their attitudes to dynastic problems and the issues of foreign policy. The Holstein party wanted to recognize Charles Frederick of Holstein-Gottorp (married to Anna Petrovna, daughter of Tsar Peter) as heir to the childless Ulrika and Frederick and thus to use him as a lever for the peaceful return of some of the lost Baltic provinces. The Hesse party opposed the Holstein candidature and sought support against it (in a rapprochement in 1727 with Great Britain) to work for a younger brother of Frederick I as heir to the throne.

When, after the death of Catherine I of Russia in 1727, Charles Frederick lost Russian support, party distinctions developed between the Hats (alluding to the cocked hats of the military, anxious to get back, if need be by force, part of the lost empire) and the Caps (alluding to nightcaps), intent on a pacific policy. At the *Riksdag* of 1738 the Hats emerged as a fully organized party, won election to important committees, and forced the

resignation of Count Arvid Bernhard Horn (*q.v.*), the leading statesman of the 1720s and 1730s. The Hats remained in power until 1765, though from 1740 onward the two parties were evenly balanced in the *Riksdag*. The Hats' economic outlook was protectionist; they encouraged trade and manufactures and introduced reforms in the system of landholdings and the methods of agriculture. In their foreign policy they aimed to strengthen Sweden's armed forces and to demand a modification of the Treaty of Nystad. In 1741, in return for a promise of part of the former Swedish Baltic territories, Sweden gave support to Elizabeth, daughter of Peter the Great, in her successful coup against Tsar Ivan VI. The promise was not carried out, however; instead, in 1742 Elizabeth turned against Sweden.

The ensuing war was disastrous for Sweden, Finland being occupied by the Russians in 1742. The issue of the succession now became acute, Ulrika Eleonora having died in 1741. The most favoured candidates were the Danish crown prince, Frederick, and Peter Ulrich of Holstein-Gottorp, son of Charles Frederick and Anna Petrovna. Peter, however, was chosen by the Russian empress Elizabeth as her own heir, and at the Peace of Åbo (August 1743) Sweden, in return for the restitution of Finland, was forced to accept as crown prince a candidate picked by Russia, the prince-bishop Adolphus Frederick, also of the Holstein-Gottorp family. This peace made Sweden dependent on Russia. But temporary cooperation between the moderate Hats, led by Count Carl Gustaf Tessin (*q.v.*), and the Caps put an end to such dependence within a year. Friendly relations were reestablished with Denmark-Norway; the Russian troops on Swedish soil (there to prevent any intervention by Denmark on behalf of their crown prince) agreed to leave, and a bride (Louisa Ulrika, sister of Frederick the Great of Prussia) was found for the Russian-imposed Swedish heir from an anti-Russian court.

After 1744, however, strong party divisions reappeared, the Hats being supported by France and the Caps by a combination of Great Britain, Russia, and Denmark. The Hats had some success in their attempts to wean Denmark to their side; a treaty of friendship was signed between Sweden and Denmark in 1749, and in 1751 Gustavus (later Gustavus III), the son born to Adolphus Frederick and Louisa Ulrika in 1746, was betrothed to Sophia Magdalena, daughter of Frederick V of Denmark. The brilliant and ambitious Louisa Ulrika resented the Hats' enforcing this engagement, and she began to build a court party round her, dedicated to increasing the power of the crown once her husband should succeed Frederick I.

The intellectual life of the reign of Frederick I was lively, with a strong emphasis on the practical application of ideas. The compilation and modernization of the laws of Sweden (begun in the reign of Charles XII) was finished in 1734; newspapers and political pamphlets attracted writers of the calibre of Olof Dalling; Carolus Linnaeus (*q.v.*) undertook a tour of Sweden to suggest improvements in agriculture; the Academy of Science was founded in 1739 and the Statistical Office in 1749. (R. M. HA.)

**3. Adolphus Frederick (1751-71).**—King Frederick died in 1751 and was succeeded by Adolphus Frederick (*q.v.*), who was under the influence of his stronger-minded wife. Tension between the king and council grew. In 1756 a rash effort at a *coup d'état* on behalf of Adolphus, instigated by his wife, failed. The royal couple were humiliated. They were threatened with dethronement in an act passed by the *Riksdag*; some of their friends were impeached and executed; and an autograph stamp was introduced in order to dispense with the king's personal intervention in government. Count Fredrik Axel von Fersen (*q.v.*), the foremost man in the Hat Party, was chosen in 1756 as *lantmarskalk* (speaker of the First Estate, the nobility).

Opposition grew therefore among the unprivileged classes against the nobility and the bureaucracy. The state's finances were in a serious condition, yet in spite of this, in 1757 Sweden was drawn into the Seven Years' War (*q.v.*), on the side of France and Austria, against Frederick II the Great of Prussia, largely because of French subsidies. The Swedish campaigns were badly managed, but peace was made with Prussia without loss of territory in May 1762. The Caps took office in the *Riksdag* of 1765-

66. Russia and Prussia together decided to support the Swedish constitution, to prolong its general state of weakness, and at the same time to work against French influence. A Russo-Danish alliance was also formed with the purpose of maintaining the Swedish constitution. England was on the same side, and it is calculated that these powers spent 3,000,000 silver dalers to ensure the victory of the Caps, while France's contribution to the Hats was 2,000,000 dalers. Against the wishes of Adolphus and his wife, the crown prince Gustavus married the Danish princess Sophia Magdalena in October 1766.

The court had helped the Hats during the *Riksdag* of 1765-66. At the end of 1768, in order to overthrow the Caps, the king temporarily abdicated, thus forcing the council to call an extraordinary *Riksdag* which sat from 1769 till 1770. The Caps were now in a minority and their men were left out of the council, which was controlled by the Hats. The court had been promised that the king's power would be increased, but the Hats did not keep their word. Nor did the *Riksdag* succeed in solving the great financial problems.

In December 1769 Russia and Denmark came to an agreement that, should any change be made in the constitution of Sweden in the direction of increasing the king's power, they would uphold the existing constitution by force of arms. In February 1771 Adolphus Frederick died.

#### G. ROYAL REACTION, 1772-1809

**1. Gustavus III (1771-92).**—The crown prince, who now became Gustavus III (*q.v.*), was in Paris when his father died. He returned home to meet the *Riksdag*. The Hats and the court party were receiving money from France, the Caps from Russia and England. The parties were of about equal strength. Gustavus now decided to precipitate a change of the constitution. Col. Jacob Magnus Sprengporten crossed to Finland and succeeded in stirring up a rising. Johan Kristoffer Toll, a superintendent of forests, went to Skåne and won over the garrison at Kristianstad (Aug. 12, 1772). The council received news of the danger, however, so the king had to act speedily. On Aug. 19 he collected around him the officers of the guard and arrested the council in the royal castle at Stockholm. The Stockholm troops declared for him, and the people acclaimed him in the streets. On Aug. 21 a new constitution was approved. The king became again head of the government, with the right to appoint officials. Russia and Denmark were deterred from declaring war by France, which remained firm in its support of Gustavus.

Gustavus surrounded himself with capable men. Unusually gifted, but a visionary, he took an active interest in all spheres of government. Reforms were instituted in the administration and in judicial procedure; torture was forbidden; religious toleration was granted to dissenters, and from 1777 a comprehensive reform of the currency was carried out. To help the finances, distilling was decreed a royal monopoly and a number of distilleries were founded by the crown. This, however, created discontent among the peasantry and resulted in the growth of illicit distilling and a large increase in drunkenness. Another cause for dissatisfaction lay in the king's efforts to transform the nobility into a court nobility and to manage civil-service promotions so as to break the power of the old bureaucracy. In the *Riksdag* of 1786 Gustavus met with fierce opposition and most of his reforming policies were rejected.

Turkey's war with Russia in 1787 seemed to offer favourable conditions for foreign policy. Gustavus declared war on Russia in June 1788, taking command himself. A naval battle in July, off the island of Hogland, in the Gulf of Finland, was indecisive. In August a conspiracy, known as the Anjala League, was formed at Anjala, on the Russian-Finnish border, by a group of Swedish officers who opened peace negotiations with Catherine II of Russia. News now came that Denmark had entered the war as Russia's ally and had invaded Sweden. Gustavus hurried home and toured the country to rally support. Sweden was swept by a wave of patriotism. England and Prussia brought pressure to bear on Denmark and a truce was concluded between Denmark and Sweden.

By the beginning of 1789 Gustavus was strong enough to have the leaders of the Anjala League imprisoned. The *Riksdag*, called in February, proved to be stormy. The king, supported by the unprivileged Estates, drove through the Act of Union and Security (Feb. 21, 1789), which embodied far-reaching constitutional innovations: the council ceased to exist, the king acquired full powers over the administration of the state and the appointing of officials, and the *Riksdag* lost its initiative in legislation. Once again the authority of the king was dominant. The *Riksdag* became responsible for the national debts, the management of which was placed in the hands of a new department, the *Riksgäldskontor*, which was dependent on the *Riksdag* and which was given the right to take up new loans and to issue credit notes.

The Russian war on land became a war of exhaustion. During 1789–90 there were several naval battles, and at Svenskund (July 9–10, 1790) Sweden gained a great victory under the king's command. In August peace was concluded at Värälä without modification of frontiers. But Sweden's finances had been destroyed, and the internal strife now came to a head. One result was a conspiracy against the king's life. He died on March 29, 1792, after being attacked by an assassin.

**2. Gustavus IV (1792–1809).**—At the age of 13 Gustavus IV (*q.v.*) became king of Sweden with his uncle Charles, duke of Södermanland (later King Charles XIII), as regent. Duke Charles's closest associate was Baron Gustaf Adolf Reuterholm, a man of great powers of work but pedantic and of little intelligence. The regency brought order into the higher grades of government service and aimed to help agriculture. Reuterholm was not lacking in appreciation of the latest reforms: the limited freedom of the press, first instituted in 1766, was increased, but when the Terror of the French Revolution broke out (1792) it was restricted. The regency did not stand very high in repute. It wavered between a French and a Russian alliance. The king, the duke, and Reuterholm visited the Russian court in 1796 in order to arrange a marriage between the king and Alexandra, granddaughter of Catherine II, but the plan was abandoned when the king refused to give a guarantee for the princess to practise her Orthodox faith. On the basis of a treaty concluded with Denmark in 1794, the fleets of both Denmark and Sweden sought to protect neutral trade against privateers of England and other nations.

In 1796 Gustavus IV took the government into his own hands. He was scantily gifted but, combining obstinacy with passionate temper, he knew how to make himself felt. So bad were the state finances that the town of Wismar had to be mortgaged to Mecklenburg in 1801. In the course of a long journey in Germany in 1803–04 Gustavus came into touch with French *émigrés*, who inspired him with hatred of Napoleon. He joined the coalition of England, Russia, and Austria against France (1805–07) with the result that Pomerania and Stralsund, Sweden's last possessions in Germany, were lost. In the Treaty of Tilsit (July 1807) Napoleon and Alexander I of Russia agreed to attack Sweden unless it declared war against England, and they prevailed on Denmark to do the same. On Gustavus' refusing to break with England, Russia in February 1808 invaded Finland, where the army gave way. In the spring the Swedes marched again to the south of Finland and won several victories, afterward immortalized by the poet Johan Ludvig Runeberg (*q.v.*). The victories, however, were not decisive, and after the strong fortress of Sveaborg was treacherously surrendered (May) the Swedes again retreated and in December evacuated Finland. Gustavus became more and more difficult, annoying even England, his only ally. The feeling grew that the king must be dethroned. Gen. Georg Adlersparre started a revolutionary movement in Värmland (March 1809), but before he reached Stockholm Adj. Gen. Karl Johan Adlercreutz had seized the king (March 13, 1809), who was deposed and died in exile in 1837.

#### H. THE 19TH CENTURY

**1. Charles XIII (1809–18).**—The *Riksdag*, called together on May 1 by the provisional government under the regent Charles, duke of Södermanland, decided to draw up a new constitution and elect a king. The form of government which resulted was based on

a division of power among the ministry, the representatives of the people, and the judicature. The king was to be advised by a ministry the members of which were to be appointed by him but to be answerable to the *Riksdag*. General legislation was to be the work of the king and the *Riksdag*, and the *Riksdag's* control over taxation was confirmed. As soon as this constitution had been adopted (June 6, 1809) the regent was recognized as King Charles XIII (*q.v.*). Charles was 61 years old and childless, and it was necessary to choose his successor. Public opinion in Sweden at this period was occupied with the possibility of a union of Norway and Sweden as a compensation for the loss of Finland. The *Riksdag* therefore chose as Charles's successor Prince Christian Augustus of Augustenburg, commander in chief in Norway, who declared that he could accept the offer only after a declaration of peace. During the late summer of 1809 the Russian war was extended to the north of Sweden and the Swedish forces met with two defeats. The Russians in the meantime had become weary of the war, and in September 1809 peace was concluded at Fredrikshamn (Hamina); Sweden lost Finland and Åland. Treaties of peace followed in 1810 with Denmark and France, which returned Swedish Pomerania to Sweden.

The heir to the throne, who had taken the name of Charles, died suddenly in 1810, and a *Riksdag* at Örebro had again to deal with the succession. Opinions were divided when a suggestion was made to elect one of Napoleon's marshals, Jean Bernadotte, prince of Pontecorvo. It seemed certain that Napoleon would approve, and Bernadotte was chosen. He assumed the name of Charles John. Charles XIII, though he had shown courage and patriotic feeling during Gustavus III's war with Russia, was not very intelligent and lacked strength of character. The crown prince therefore began to exert considerable influence, with beneficent results.

In 1812 Napoleon began his campaign against Russia. The crown prince perceived that Sweden could not possibly benefit from fighting with France against England and Russia; he seemed also to have thought out already his plans for conquest of Norway. In 1812 therefore he brought about a complete change in Swedish foreign policy. Napoleon's occupation of Swedish Pomerania (January 1812) facilitated the change, and Russia and England favoured the idea of Norway's passing to Sweden from Napoleon's ally Denmark. Sweden therefore concluded alliances with Russia (April 1812), Great Britain (March 1813), and Prussia (April 1813). After the defeat of the French armies in Russia, Charles John took part in the final campaigns as commander of the northern army, with Swedish as well as Prussian and Russian troops under him. With these the crown prince, after the battle of Leipzig (October 1813), turned against Denmark, which by the Peace of Kiel (January 1814) was forced to hand over Norway. By the Treaty of Vienna (1815), Swedish Pomerania was given to Prussia.

The Norwegians themselves, desiring independence, held an assembly at Eidsvoll (May 1814), where they framed a constitution and elected the Danish prince Christian Frederick as king; but a short war with Sweden forced them to surrender. Christian Frederick laid down his crown and a *Storting* (national legislative assembly) endorsed the union with Sweden. The act of union or *riksakt* was passed by the Parliaments of both countries in 1815; Norway retained its independence and its constitution, but remained united with Sweden. (K. H.; E. O. H. J.)

**2. Charles XIV (1818–44).**—In 1818 Bernadotte succeeded to the throne, as Charles XIV (*q.v.*) John, founder of a new dynasty. He was a strong personality, capable and lovable, but distrustful of new ideas and apprehensive of too great changes. A liberal opposition in the *Riksdag*, above all among the burghers, took a strong line against the government's repression of newspapers, against bureaucratic formalities, and against the king's tendency to disregard his ministers' advice. From the 1830s onward there was a question of reform in the matter of the representation of the people, and a great many bills were put forward without much success. In 1840 the state council was changed by the creation of special departments. In 1834 the currency was devalued. Much was done to develop the canal system; one section of the Göta

Canal was opened in 1822 and the rest in 1832. In 1842 compulsory elementary school education was established. In consequence of growing agrarian production (for instance of potatoes) and a reduction in the mortality rate, partly resulting from compulsory vaccination against smallpox, the population increased rapidly (from 2,500,000 in 1815 to 3,300,000 in 1845). This increase caused serious social problems in the countryside, where 90% of the people lived, particularly among the elderly working-class poor.

3. **Oscar I (1844-59).**—Charles XIV was succeeded in 1844 by his more liberal son Oscar I (*q.v.*). During Oscar's reign the industrial economic revolution began in Sweden. The expansion of the sawmill and iron industries was rapid, due partly to new machines and methods, and exports grew considerably. Restrictions on agriculture and commerce were relaxed; the guild system was done away with in 1846, and the old rules confining trade to the towns were removed. By decisions reached in the *Riksdag* for 1844-45 the right to suppress newspapers was definitely abrogated. In 1847 an important poor law system providing organized relief was introduced. One of the greatest questions of the period was that of communication: railways had to be built, but there were differences of opinion as to the laying down of the main lines through the sparsely inhabited land. In the *Riksdag* of 1853-54 it was decided that the main lines should be built by the state.

Friends of reform concentrated more and more on the demand for a thoroughgoing change in the formation of the *Riksdag*, and many proposals were submitted without any being accepted. The revolutionary movement which marked the year 1848 on the continent aroused feeling also in Sweden, and some street disturbances occurred in Stockholm. The government produced a new scheme of representation, which, however, was rejected by the *Riksdag* of 1850. A strong Scandinavian movement manifested itself (especially in Denmark and Sweden, although the Norwegians also took part in it); great meetings of students were held, but no program for the unity of the Scandinavian countries with any real life in it was ever framed.

When the Schleswig question led in 1848 to war between Denmark and the German states (*see SCHLESWIG-HOLSTEIN QUESTION*), a Swedish army was collected in Skåne and troops were carried over to the Danish island of Fyn, in case Jutland should be invaded; but they never had occasion to come into action. During the Crimean War (1854-56) Sweden and Norway maintained neutrality, and in November 1855 they reaped the benefit: a treaty (known as the November Treaty) was concluded with England and France by which the union states undertook not to cede any portion of their territories to Russia, while the two other powers undertook to prevent any Russian efforts in that direction. Side by side with the peace treaty in Paris ending the Crimean War (1856) there was concluded a separate agreement among Russia, France, and England in which Russia undertook not to fortify the Åland Islands.

The increasing consumption of spirits, as a result of the right to distill for household needs (legalized in 1787), led to a temperance movement conducted by persons such as Peter Wieselgren, a pastor. Private distilleries were forbidden by the *Riksdag* of 1853-54 and the distilling of spirits was regulated by the state.

4. **Charles XV (1859-72).**—The crown prince had already, because of his father's ill health, conducted the government for two years when in July 1859 he became king as Charles XV (*q.v.*). His liveliness of mind, personal friendliness, and artistic temperament won him great popularity, but he lacked thoroughness and perseverance and his extravagant imagination in certain situations was a danger. This became most noticeable in the German-Danish war of 1864 over Schleswig-Holstein, when he gave the Danes to understand that they could count on an alliance between Denmark and Sweden-Norway, an idea which had never had the sanction of the state councils of either of the union countries. A number of Swedes, however, did enter the Danish army as volunteers.

The social changes which had come about in the life of Sweden, including the decline in importance of the nobility and clergy in social and cultural life and the rise of commoners to high positions in the bureaucracy, necessitated a new form of electoral repre-

sentation, and increasingly the general feeling was that the problem could be solved only by replacing the *Riksdag* of the four Estates by one with two chambers. The minister of justice, Louis de Geer, took the lead in the matter, and the government submitted a bill to this effect in the *Riksdag* of 1862-63. The new constitution was finally accepted by all four Estates in the *Riksdag* of 1865-66, and in January 1867 the first *Riksdag* of the new kind was assembled. The first chamber was composed solely of aristocrats, businessmen, and high officials and was elected by councils, which were themselves elected by a graded scale of voting, industrial and commercial companies and the rich having far more votes than the poor. The second chamber comprised members of the bourgeoisie and farmers and was elected by about 25% of the population, the right to vote being based on a property qualification too high to include the majority of the working class. It soon became evident that it was the peasants who had benefited most by the reform: within two years they dominated the second chamber and their party—the so-called Lantmanna Party—was a power to reckon with.

Through the influence of the finance minister, Baron J. A. G ripenstedt, Sweden was led more in the direction of free trade, and its treaty of commerce with France in 1865 was an important landmark in this development. All duties on grain were removed. In 1864 internal free trade had finally been established. Among other important reforms may be mentioned the criminal law of 1864 by which imprisonment became the main punishment for crime. The wars in progress on the continent caused the *Riksdag* to make some grants for armaments, but the government's proposal for a reorganization of the national defenses was rejected. The birth rate remained higher than the mortality rate, and from the 1850s part of the expanding population, especially those of the working class, began to move to the U.S. This emigration reached its first climax after the famine of 1867-68.

5. **Oscar II (1872-1907).**—After a prolonged illness Charles XV died in 1872 and was succeeded by his brother Oscar II (*q.v.*). The most noteworthy event in the latter's reign was the dissolution of the union with Norway. The position of the sovereign of the two countries had become extremely difficult, because modern parliamentarianism had progressed much farther in Norway than in Sweden and the power of the sovereign had consequently become much less extensive in Norway. On June 7, 1905, the Norwegian *Storting* declared the union with Sweden to be dissolved. The *Riksdag* finally agreed to the dissolution on certain conditions, and in October 1905 Oscar laid down the Norwegian crown (for details of the dissolution of the union *see NORWAY: History*).

During the first years of Oscar II's reign, the question of national defense had been the dominant one, the first chamber of the *Riksdag* contending for an improved system and the peasant members in the second chamber making demands for the abolition of the old land taxes and of the old army organization, which was very burdensome for the peasants. A number of army organization proposals were rejected, but in 1885 the *Riksdag* carried out a compromise: military service was increased from 30 to 42 days, and the state became responsible for part of the costs of the army organization and reduced the land taxes.

During the 1880s the question of customs duties caused bitter disputes. The increasing exportation of grain from the United States and Russia, together with the strong industrial competition among all countries, resulted in a protectionist movement in Germany and France which extended also to Sweden. The agrarian prices dropped sharply and emigration increased. The second chamber was protectionist and the first in favour of free trade; in 1887 the majority in the first chamber was so small that it would have been possible to bring about a protectionist system by the collective vote of the two chambers. The king then dissolved the second chamber, which returned with a majority in favour of free trade. But in the general election in the autumn of 1887 a technical mistake in the election of free trade candidates in Stockholm made their election invalid, with the result that the protectionists gained a small majority. The *Riksdag* of 1888 therefore accepted the customs system.

This issue had profound consequences both in the formation of parties in the second chamber and in other respects. New men came forward, the most conspicuous of whom was a Conservative, the landed proprietor E. G. Boström, premier from 1891 to 1900 and from 1902 to 1905. The question of the national defenses was provisionally settled by the *Riksdag*'s decisions in the autumn of 1892 (at an extraordinary session), and then finally in 1901. In the latter year the *indelning* system was completely abolished; all males were now liable for military service and the training time was increased from 90 to 240 days in the infantry and a longer period in the case of the navy and special branches of the army. The land taxes were abolished in 1892.

At this period new legislation was necessitated by industrial development and the great increase in the number of industrial workers. New methods led to an enormous expansion of exports of paper pulp and iron ore. In 1900 Sweden had 5,150,000 inhabitants, of whom 22% lived in the towns. Between 1870 and 1900 the proportion of the population engaged in industry and commerce increased from 20% to 35%. In 1881 the conditions of labour for children in all factories were regulated and in 1889 a law was passed providing against injury while at work. The child labour law was amplified in 1900 by one dealing with the condition of industrial work for women and children. Trade unions were formed and collective agreements governing labour conditions were arranged between employers and workers.

In 1889 a Social Democratic Party was formed, and in the autumn of 1896 Karl Hjalmar Branting (*q.v.*) was elected to the second chamber as its first Social Democratic member. In 1900 the Liberal groups of the second chamber merged into one great party. The Liberals and Social Democrats demanded an extension of the suffrage for the election of the second chamber, but it was not until the severance of the union with Norway had given a strong impetus to a closer national union on new lines that the question came to be decided. The severance of the union led to the formation of the coalition ministry of Christian Lundeborg, a manufacturer, whose task it was to carry out the dissolution of the union. He was followed at the close of 1905 by a Liberal ministry with Karl Staaff as premier. The *Riksdag* of 1906 rejected his suffrage bill, and the ministry resigned. Rear Adm. Arvid Lindman succeeded, with a Conservative ministry; he found a way, in 1907, of solving the suffrage question on the basis of universal suffrage for men for the second chamber; the democratization of the graded scale of voting for the first chamber (no voter was allowed to have more than 40 votes); and proportional representation for both chambers. Among other important decisions may be mentioned the monopoly in the issuing of bank notes accorded to the Riksbank in 1897, the building (1898-1902) of a Swedish-Norwegian railway for the exportation of the Lapponian iron ore, the restriction of the right of companies to acquire land in northern Sweden (1906), and the part ownership of the state in the Lapland iron ore mines (1907).

(K. Hl.; S. C. O. C.)

## I. THE 20TH CENTURY

When Oscar II died on Dec. 8, 1907, the crown fell to his eldest son, Gustav (Gustavus V; *q.v.*), who proved a capable king for a democratic epoch. Reforms were carried through, as, for instance, the law (1909) allowing peasants in Norrland to acquire land and leave it to heirs. In the summer of 1909 a great trial of strength between the industrial workers' trade unions and employers' associations culminated in an unsuccessful general strike. In the autumn of 1911 the election for the second chamber of the *Riksdag* was held with a doubled electorate as a result of the reform bill of 1907, and the Lindman ministry resigned. Karl Staaff formed his second ministry. His government set aside the Lindman ministry's decision to build a warship of a new type, whereupon a movement to finance its construction by private subscription produced a sum of 18,100,000 kronor and the ship was built.

The Swedish people had been disquieted by the way in which the Russians were arming in Finland and by widespread Russian espionage in Sweden, and in February 1914, 30,000 peasants met

in Stockholm to request the king that a comprehensive national defense plan be drawn up. When the king's answer was favourable, the Liberal ministry resigned. The king commanded the Conservative Hjalmar Hammarskjöld (*q.v.*) to form a ministry. K. A. Wallenberg became minister of foreign affairs. The second chamber was dissolved and elections were held on May 1. When the *Riksdag* reassembled the government had a majority in the first but not in the second chamber.

**1. World War I.**—By the outbreak of World War I Sweden found itself more or less isolated from the armed blocs in Western Europe, from which it bought a large proportion of its food supplies, raw materials, and finished goods. Sweden declared itself a neutral power, measures for the reorganization of defense were passed, and Sweden succeeded in preserving its neutrality throughout the war despite external and even some internal pressure by activists favouring one or the other side. At the same time a common policy of neutrality bound the three Scandinavian states together and erased some of the bitter feelings between Sweden and Norway. At first industry and commerce took an upward swing owing to large purchases by the belligerents; soon, however, this intensive buying exhausted stocks which could no longer be replenished, and the export of some goods was therefore made subject to licence. The state also confiscated sugar and other foodstuffs at fixed prices and distributed them by rationing and took over certain imports. At times there was an extreme shortage of some foodstuffs.

In 1917 the Hammarskjöld government resigned over the supply position. A Conservative ministry carried on for a short time until the general elections which brought considerable gains for the Social Democrats. A Liberal-Socialist coalition under Nils Edén took over, and Hjalmar Branting, Sweden's most famous Socialist, entered the government for the first time as minister of finance. The supply problem was solved by two agreements with Great Britain, the second one being the so-called *modus vivendi* agreement concluded in March 1918, providing for the limited import of vital goods in exchange for the loan of a large part of the Swedish merchant fleet and the substantial reduction of exports to Germany. The Russian and, following it, the German Revolution seriously affected Swedish thought and led to a revival of demands for democratization of the constitution. As a consequence, a special session (*urtima*) of the *Riksdag* passed a radical bill that included *inter alia* votes for women. One effect of the bill was to make the Social Democrats the strongest party in the *Riksdag*; the Conservatives were the second strongest. The Liberals, who lost some seats, split into two groups in 1923—the National Liberals (Folksfrisinnade) and the Liberals—thereby further weakening their position. A small Communist Party and a Farmers' Party were also formed.

Another consequence of the Russian Revolution, Finland's secession from the Russian empire, also affected Sweden. While the government recognized Finland's independence in January 1918 it did not dare grant military aid to the new nation lest this involve Sweden in the war or lead to difficulties at home, since the sympathies of left wing Social Democrats were with the soviets while a strong bourgeois opinion demanded aid for the tsarist. The government's policy adversely affected Finno-Swedish relations, and Finnish resentment was further increased by the dispatch of a Swedish naval expedition to the Åland Islands in February 1918, when the islands were threatened by a Russian landing. Finnish circles interpreted this action as an attempt to express practical sympathy with an earlier demand by the Ålanders to join the Swedish realm. Not until after Sweden's calm acceptance of the League of Nations' decision (1920) in favour of Finland's retention of the islands did this resentment gradually die down.

**2. The Interwar Period.**—The most striking development between World Wars I and II was the great advance of the Social Democratic Party. In 1920 the Liberal-Socialist coalition was followed by the first purely Social Democratic government under Branting, but the autumn elections resulted in a small setback to his party. A "business" ministry of a moderately Conservative character thereupon carried on until after the 1921 elections, when

Branting again formed a government. This remained in office until 1923 and was followed by a number of short-term governments from the right or from the left, including a Liberal government under Carl Ekman which commanded only 33 votes from 231 seats but nevertheless carried on from June 1926 to the general elections in 1928. During this period the Social Democrats succeeded in passing a bill which greatly reduced armaments. In 1928 a Conservative government took office but was soon defeated. Another Liberal government, formed in 1930, resigned in 1932 after the autumn elections when the Social Democrats and the Farmers made considerable gains.

In October 1932 the Social Democrat Per Albin Hansson (*q.v.*) formed his first ministry. Its program included strong measures to overcome the depression (*see below*) and aimed at financial expansion rather than economies. When the Social Democratic Party proved not strong enough to enforce these measures, an arrangement (the so-called *Kohandel*) with the Farmers was concluded (1933) and the opposition had to yield. Gradually developments in industry began to justify the government measures, and unemployment began to fall steeply. Apart from a few months in 1934, when the Farmers governed alone, the Social Democrats—either alone or in coalition with others—remained in office throughout the ensuing period, and in the elections in 1934 they nearly attained an overall majority. The feeling of security of tenure which their strong position gave them was reflected in the increasing atmosphere of calm that prevailed in labour relations and led to a standardization of the so-called collective agreements which by 1940 covered about 1,000,000 workmen.

The economic effects of the post-World War I crisis had affected Sweden. Early in 1922 unemployment rose to 160,000, but by the close of that year the nadir had been reached and Sweden's recovery kept step with that of the outside world. At the same time the democratization of the country increasingly affected the economic field. Labour had earlier been organized into trade unions and the cooperative movement flourished, but revolutionary ideas no longer prevailed; a policy of "progress by peaceful negotiation" was begun. The eight-hour day was introduced without wage reduction and, despite shorter working hours, production expanded. The merchant fleet was substantially increased, the production of pulp was assisted by improved forestry, seed selection was introduced for the benefit of agriculture, and highly developed engineering works produced increasing quantities of goods for export. Sweden also became one of the countries which exported capital.

During the depression of the early 1930s a number of grave labour conflicts occurred; Sweden followed Great Britain in abandoning the gold standard, which relieved the position temporarily, but it was still serious when the Social Democrats resumed office in 1932 and it improved only gradually. After World War I Sweden supported the League of Nations, prepared even to abandon in part its policy of neutrality. The gradual deterioration of the international situation, however, as well as the advent of the Nazis in Germany and the failure of the League to save Ethiopia, induced the government to reconsider the situation. Defense again became a primary consideration, although a law passed in 1936 aimed rather at the modernization of the army than at its expansion. After the German invasion of Austria (1938) Hansson promptly proposed increases in defense and Sweden advised the League that it proposed to resume its strict neutrality policy. The fall of Czechoslovakia (1939) further pointed the danger. Sweden declined Germany's offer of a nonaggression pact, but Swedish attempts to

bring about closer inter-Scandinavian relations and to cooperate with Finland in a possible defense of the unfortified Åland Islands failed, the latter because of Soviet opposition.

**3. World War II.**—On the outbreak of World War II the Social Democratic government strengthened defense and proclaimed the country's official neutrality. A comprehensive war trade agreement was concluded with Great Britain in December 1939, and after the outbreak of the Russo-Finnish War (November 1939) a coalition government of all parties was formed. The material aid given to Finland was of unparalleled generosity and endangered Sweden's own security, but Finnish requests for regular troops were refused although volunteers were helped and encouraged. Allied demands for the transit of British and French troops to Finland were rejected by Sweden as well as Norway.

The German invasion of Denmark and Norway (April 1940) isolated Sweden from the West. Despite heavy German pressure to allow the transit of troops and armaments, not until after the end of the war in Norway (June 1940) did Sweden enter into an agreement permitting German soldiers on leave, and goods, including war material, to pass over certain Swedish railways. On the outbreak of the second Russo-Finnish war (June 1941) Sweden was forced to a still greater concession. On June 25, 1941, permission for the transit of a whole armed division from Norway to Finland was granted. These agreements aroused bitterness and criticism in Sweden and brought sharp Allied protests. The traffic was ended in the late summer of 1943 after Germany's position had deteriorated and Sweden's military strength increased. Stringent reductions in Swedish exports to Germany were also made, and a comprehensive new war trade agreement was concluded with Britain and the United States.

Despite its precarious position Sweden succeeded in avoiding all German attempts to persuade it to participate in the German "new order" policy, and all through the war Sweden was a shelter for refugees from German oppression, not only Norwegians, Danes, and Finns but also Balts and Jews of all nationalities. After the war, relief, largely in the form of credits, amounting to about \$600,000,000 was extended mainly to Norway and Denmark, and medical supplies, food, and clothing were sent wherever needed. The Swedish Red Cross under Count Folke Bernadotte was actively engaged in aiding prisoners of war with the government's generous support.

**4. The Postwar Period.**—After World War II the Social Democrats dissolved the coalition and governed alone. The first post-war elections (1948) confirmed them as the strongest party, but the unexpectedly slow recovery of devastated Europe, the cumulative effect of unfavourable world trends, Europe's growing economic dependence on the United States, and the temporary elimination of Germany from world trade seriously affected Sweden's economy. Sweden had adopted a generous foreign credit policy to aid European revival; when the expected revival did not materialize, an economic crisis ensued. Large cuts had to be made in imports and expenditure was reduced, although this never affected expenditure on social welfare or defense.

King Gustav died in 1950 at the age of 92, and his son Gustav VI Adolf (Gustavus VI; *g.v.*), who was 67, succeeded to the throne. In October 1946, after the death of Hansson, Tage Erlander became prime minister and in 1951 formed another coalition with the Farmers. Gradually the economic position improved, but the country blamed the coalition for high food prices and the 1952 elections resulted in slight losses for both government parties. The government continued to improve social services, and on Jan. 1, 1955, a compulsory health insurance scheme for the whole nation came into force. Rationing of alcohol was terminated on Oct. 1, 1955. The general elections in 1956 resulted in further losses for the coalition government, and the Social Democrats had to make important concessions to the Farmers to preserve the coalition. In October 1957 a national referendum took place on the subject of an additional national pension scheme, in which the plan advocated by the Social Democrats proved victorious. Thereupon the Farmers resigned from the government. On Oct. 31 Erlander formed a Social Democrat minority government after various attempts to form a government on a broader basis, including one to create a bourgeois coalition, had failed. The new government had a slight majority in the first chamber but could not carry through bills in both chambers if the bourgeois parties united against it.

In the spring of 1958 this precarious position became untenable when a bill advocating increases in old-age pensions and a supplementary pension for all income earners was rejected in the second chamber; and on April 28 the *Riksdag* was dissolved. During the election campaign the Liberals advocated a separate pensions proposal which did not please anybody and resulted in staggering losses for that party. The elections on June 1, 1958, gave the following results for the lower chamber: Social Democrats 111, Centre Party (the new name of the Farmers' Party) 32, Conservatives 45, Liberals 38, Communists 5. The municipal elections in the autumn confirmed the decline in Liberal fortunes. The pensions bill was not submitted until the spring of 1959, when it was passed in the second chamber by the narrowest margin, 115 to 114. Another difficulty which faced the government was a deficit of over 100,000,000 kronor shown in 1959. Not until the government made the matter one of confidence was a "turnover tax" of 4% passed, and even that was made possible only because the Communists refrained from voting, thereby saving the government.

In June 1960, just prior to the general election, Erlander stated that his party would accept a mixed economy—i.e., would accept different forms of ownership and not aim only at nationalization of industry. The elections, nevertheless, did not realize his hopes of an overall majority, nor did he achieve this at the 1964 elections, when the position in the lower chamber of the *Riksdag* was: Social Democrats 113, Liberals 42, Centre Party 35, Conservatives 32, Communists 8, Citizens Front 3. Thus the government continued to be dependent on the support of the Communists on all major issues. On June 1, 1965, after the resignation of Gunnar Heckscher, Yngve Holmberg was elected as new leader of the Conservative Party and began by continuing Heckscher's attempts to bring about a merger of the three bourgeois parties; however, owing to the determined opposition of the Liberal leader, Bertil Ohlin, to the inclusion of the Conservatives in such a merger, Holmberg abandoned his attempt, and for the time being only the Liberal and Centre parties observed a certain tacit understanding. In October 1957 the great Arctic Iron Ore Company, Luossavaara-Kirunavaara A.B., was nationalized at a cost of 825,000,000 kronor.

Sweden joined the United Nations in 1946, but the proposal for the North Atlantic Treaty Organization (NATO) led to much heart searching. A Swedish proposal of a common defense pact with Denmark and Norway failed, and the government thereupon decided to revert to its traditional policy of neutrality and not to join NATO. As a consequence, increasing amounts were spent on armaments. Sweden joined the Council of Europe, however, and actively participated in the work of O.E.E.C. and became a member of the European Free Trade Association. Sweden steadfastly supported the United Nations, contributing a battalion to the operations in the Congo, supplying officers and observers to supervise

the dismantling of the Cuban bases, and rejecting all Soviet efforts to induce it to join an "antinuclear club." On Aug. 12, 1968, Sweden signed the test ban agreement.

Sweden's relations with its Scandinavian neighbours continued to become more and more friendly and in March 1956 a Swedish-Norwegian agreement provided for greater facilities to Sweden for its transit traffic through Norwegian harbours in Trondheim Fjord, which would prove useful in time of war. Diplomatic relations with the U.S.S.R. and the Eastern European countries in 1955 and later years were affected by the discovery of cases of espionage in which members of foreign embassies were involved.

In June 1963 a former colonel of the Swedish Air Force, Stig Wennerström, was arrested for espionage on behalf of the Soviet Union. His activities had been going on for 15 years and had caused damage to Sweden's defense estimated at billions of kronor. Sweden's trade relations with the Soviet Union, on the other hand, improved during these years, especially as a result of Khrushchev's visit to Sweden in June 1964. A new trade agreement between the two countries was signed on Feb. 5, 1965, providing for Russian exports to Sweden in 1965 of 3,000,000 tons of oil and 470,000 tons of coal and coke, in exchange for Swedish exports of industrial equipment, ships, and machinery. (A. H. Hs.)

#### IV. POPULATION

Population statistics have been recorded in Sweden since 1749, when the population was about 1,780,000. Between 1810 and 1850 there was a sudden sharp rise, from about 2,400,000 to about 3,500,000, attributed to "the peace, the vaccine against smallpox, and the potatoes." In 1965 it was estimated to be 7,700,000.

The birth rate is low (14.8 per 1,000 inhabitants in 1963) and so is the fertility rate. These factors, together with the declining death rate (10.1 per 1,000 in 1963), have led to an irregular age distribution and to an unfavourable ratio between the population of working age and the increasing number of old people.

The population is low in comparison with the area of the country, and is unevenly distributed, being much denser in the south than in the north. The table shows the distribution of population according to the 1960 census, and its density, by county (*län*), as well as the relation of the counties to the provinces (*landskap*). The latter are older territorial divisions which now have no administrative status, although their names remain in common use. Stockholm city, the capital, is a governorship (*överståthållarskap*) administratively separate from Stockholm *län*.

In 1920, 55% of the population lived in villages or open country.

\*Including inland waters other than the four largest lakes, Vänern, Vättern, Mälaren, and Hjälmaren, whose combined area of 3,522 sq. mi. is, however, included in the total area. †Land area only. ‡Including the Island of Öland. §With adjacent waters.

in 1960 only 27%. The continuing urbanization has created serious social problems; e.g., in the rural areas a shortage of women and a decrease in the population of working age, and in urban areas a housing shortage. In 1964 there were 133 towns, of which 85 had over 10,000 inhabitants. After Stockholm, the largest were Göteborg (404,349 [1960]) and Malmö (228,878).

With the spread of higher education, the proportion of young people gainfully employed has decreased. For boys aged 15 to 19 it was 54% in 1960 (74% in 1950). The proportion of married women gainfully employed increased from 14% to 24%. By economic sectors the distribution of the gainfully employed showed a sharp decline in agriculture (from 20% in 1950 to 12.5% in 1962) and a rise in industry, commerce, and other service occupations. The population is racially homogeneous. In the far north there is a minority (about 0.7% of the total population) of Finns and Lapps.

Since 1930 Sweden has changed from a country with net emigration to one with regular net immigration. Poverty and unsatisfactory social conditions caused emigration to increase from 1860, and more than a million Swedes in their best years emigrated to the United States from 1861 to 1910. Then U.S. immigration laws and a rising standard of living in Sweden after World War I caused a steep decline in emigration. After World War II the number of immigrants increased considerably, reaching about 30,000 annually in certain years. During the 1950s net immigration accounted for nearly one-quarter of the total population increase.

## V. ADMINISTRATION AND SOCIAL CONDITIONS

### 1. Constitution and Government.—National Government.

Sweden is a constitutional monarchy with male succession. The constitution rests primarily on the fundamental law of 1809. The executive power is vested in the King-in-Council; i.e., in exercising his constitutional powers, the king must accept the advice of his ministers. Legislative authority is shared between the King-in-Council and the bicameral Parliament (*Riksdag*). Parliament alone has control of public finance, including the Bank of Sweden (*Riksbank*) and the National Debt Office. It also appoints two procurators general (*ombudsmän*) to supervise (1) military, and (2) all other branches of justice and administration.

Parliament is divided into an upper chamber (*första kammaren*) of 151 members and a lower chamber (*andra kammaren*) of 233 members. Members of the upper chamber are elected for eight years by the county councils and by the councils in six cities with the status of county boroughs, one-eighth of their number being reelected each year. Members of the lower chamber are elected directly for four years. Since 1921 suffrage has been universal, the minimum voting age being 21. The two chambers have equal authority, and their agreement is required to enact a bill.

As a rule, the king appoints the leader of the majority party as prime minister (*statsminister*) and asks him to form a government. The cabinet (*statsråd*) is composed of 17 members (the prime minister, the heads of the 11 ministries, and five ministers without portfolio). The king and cabinet meet merely to record and sign decisions made at the preliminary meetings of ministers. A proposal for aligning the constitution more closely with political reality and for creating a unicameral parliament was being considered by the *Riksdag* in the 1960s.

There is a sharp formal division between the policy-making executive ministries, which are mainly secretariats for their respective heads, and the 100 or so purely administrative central boards and agencies, which are subordinated to the ministries in an organizational sense only. The central administration outside the ministries is largely independent of politics, which play little part in appointment to the public service. Swedish civil servants cannot be dismissed except in the case of default and after trial.

**Local Government.**—There are two overlapping systems: as representative of the national government, a crown-appointed governor (*landshövding*) heads an administrative board in each of the 24 counties; local self-government is run by popularly elected county councils and rural or urban district councils. The governor holds supreme police authority and his office organizes local civil defense, helps in town planning and fire protection, and has some

supervisory power over the local self-government bodies. Local councils are responsible for medical facilities, social welfare, education below university level, public services, and local taxes.

**2. Political Parties.**—The distribution of seats in Parliament (both chambers) after the 1964 election was: Social Democrats (Socialdemokraterna) 191, Liberal People's Party (Folkpartiet) 68, Conservatives (Högerpartiet) 58, Agrarian Centre Party (Centerpartiet) 54, Communists (Kommunisterna) 10, Citizen's Front (Medborgerlig Samling) 3. The Social Democrats have held office continuously since 1932, sometimes in coalition with the Centre Party. Foreign policy and the large-scale social reforms have usually received the unanimous backing of all parties except the Communists; more controversial issues have been taxation, budget economics, housing policy, and farm subsidies.

**3. Taxation.**—Direct taxation is progressive, rising (in the mid-1960s), for a married couple, from more than 20% of an annual income of 20,000 kronor (about \$4,000), the average for a working class family, to about 35% of one of 50,000 kronor (about \$10,000). In addition to a general turnover tax (raised from 6% to 9% in 1965), indirect taxes are levied on alcoholic beverages, tobacco, coffee, gasoline, oil, electricity, etc. In 1963 a family with an income of 20,000 kronor paid an average of 38% in national and local direct taxes, indirect taxes, and contributions; the proportion on an income of 40,000 kronor (about \$8,000) was 46%.

**4. Labour Unions.**—The Swedish labour market is characterized by the strong central organization of both workers and employees. The Confederation of Swedish Trade Unions (Landsorganisationen, abbreviated LO) represents 95% of all workers. A major factor contributing to peaceful labour-management relations is that LO is mainly composed not of craft unions but of unions organized on an industrial basis; i.e., all workers in the same industry, irrespective of the type of work they do, belong to the same union. The Swedish Employers' Confederation (Svenska Arbetsgivareföreningen, or SAF) and LO collaborate closely on questions of mutual interest. Collective agreements on wages and conditions of employment play a dominant role in the labour market. Salaried employees also have strong central organizations. Unions, employers' organizations, consumers' and producers' co-operatives, and other popular organizations exert a considerable influence in Swedish political life.

**5. Living Conditions.**—The continuous rise during the 20th century in the Swedish standard of living can be attributed to a number of factors, not least to the uninterrupted peace the country has enjoyed since 1814. In spite of rising prices, full employment and increased productivity have led to a steady increase in real wages; for industrial workers, this was about 75% within the first 15 years after World War II. The normal income of a working class family in 1963 was about 20,000 kronor. In a salaried class family, the average income in the case of a graduate is about 40,000 kronor. Housing costs, including fuel and light, amount to 10–15% of the family budget and have remained fairly stable since before World War II, rents being controlled. In urban districts most people live in various types of multifamily dwellings, usually of good quality and well equipped with modern amenities though comparatively small, mostly with two or three living or bedrooms.

The high standard of living is reflected in the consumption of goods and services, notably of the more dispensable items such as processed foods, ready-to-wear clothing, and foreign vacations, and also in increased leisure time. Industrial workers have a 45-hour week, other employees a 42-hour week. Every employed Swede is entitled by law to four weeks' annual vacation with pay.

**6. Welfare Services.**—Sweden has an extensive system of social welfare, accounting for the largest item of expenditure in the state budget. It includes compulsory health insurance, maternity benefits, child allowances, retirement pensions, rent rebates to large families, free school lunches and school books, housing subsidies, unemployment benefits, etc. Most of these benefits are available to everybody, irrespective of personal income. The compulsory health insurance covers two-thirds of doctor's fees, hospital treatment, half the cost of medicine, and a tax-free cash sickness benefit.

Basic retirement pensions, adjusted to the cost of living, are paid to all citizens from the age of 67, regardless of income. Over and above this tax-financed, flat-rate national pension, a national supplementary pension, related to previous earned income and protected against inflation, was introduced in 1960; it is financed by employers. The two pensions together equal about two-thirds of the average yearly income earned during the 15 best years of gainful employment.

**7. Justice.**—The Swedish legal system derives ultimately from the medieval provincial laws. The first national code was introduced in the mid-14th century and was later replaced by that of 1734, on which subsequent development is based.

Both civil and criminal cases are tried in the first instance by the rural or municipal courts. The rural court (*häradsrätt*) consists of a trained lawyer as judge and from seven to nine elected laymen (*nämndemän*). If seven *nämndemän* are unanimously of a different opinion from the judge, they can overrule him. The municipal court (*rådhusrätt*) consists of the mayor (*borgmästare*), who is a permanent official and always a lawyer, and at least two other legally qualified persons (*rådmän*). The six Courts of Appeal (*hovrätter*) are next in rank; they sit in Umeå, Sundsvall, Stockholm, Göteborg, Jönköping, and Malmö. The highest tribunal is the Supreme Court of Justice (*högsta domstolen*) in Stockholm. Among special courts is the Labour Court for employer-worker disputes.

The guiding principle of amendments to the law has been to reform the offender and, by giving him vocational training, enable him to make a fresh start following his imprisonment. More than half of the existing prisons are run as open institutions. There is no death penalty.

**8. Education.**—Elementary education from the age of seven became free and compulsory in 1842. A far-reaching reform of the school system was initiated in 1962, after more than a decade of extensive experiment, with the introduction of a nine-year comprehensive school, without any concluding examination, planned to replace existing primary and lower secondary schools by 1972. In the new schools compulsory schooling ends, at the age of 16, with form 9, which is divided into a number of branches: one for further theoretical studies in an advanced secondary school (*gymnasium*); others for general humanistic, technical, commercial, or social-economic studies; and one for preparatory vocational training. Teaching of foreign languages begins in the fourth grade with English; German or French is optional from grade 7. Pupils wishing to continue their studies after the ninth year (about 40% of the age group) have three choices: the three-year *gymnasium* which prepares for university entrance; the two-year, examination-free continuation school; and vocational schools with courses of up to four years.

Besides the two old universities in Uppsala (founded in 1477) and Lund (1668), there are universities in Stockholm, Göteborg, and Umeå. Various other institutions of technology, forestry, agriculture, commerce, dentistry, etc., have university status. A considerable expansion of the facilities at institutions of higher learning is in progress. Adult education activities are an outstanding feature of Swedish cultural life and are given substantial state support. People's high schools (*folkhögskolor*), run by county councils or by cultural, social, political, or religious organizations, aim at awakening interest in social and cultural questions among young people who have normally been gainfully employed for several years. Tuition is free in practically all of the schools as well as in the universities and colleges.

**9. Defense.**—Sweden's policy of nonalignment in peacetime and neutrality in wartime is backed by a defense which is comparatively strong for a small nation and is the second largest item of state expenditure. A supreme commander coordinates activities of the services and directs military planning. Military service is compulsory for all males between ages 18 and 47. Training lasts ten months, followed by three one-month refresher periods.

A highly mechanized army of 700,000 men can be mobilized at short notice. The Home Guard, recruited voluntarily mainly from the age groups under 18 and over 47, is an integral part of the Army. The main object of the Royal Swedish Navy and the

Royal Coast Artillery is to protect the long coast against invasion from the sea. Development in the Navy is toward a system of small mobile units operating from well-protected bases tunneled into solid rock. The Swedish Air Force, as befits its defensive role, is mainly composed of fighter and reconnaissance aircraft. Equipment includes supersonic fighters of Swedish design, carrying U.S. Falcon missiles, and British Bloodhound ground-to-air missiles. During the 1960s an advanced multipurpose aircraft, the System 37 Viggen, was being developed for service at the end of the decade.

Every able-bodied Swedish citizen between 16 and 65 years of age who does not belong to the armed forces is liable to serve in the Civil Defense, the basic policy of which is mass evacuation and widespread provision of sub-rock and other shelters.

## VI. THE ECONOMY

The transition of the Swedish economy from a primarily agricultural to a primarily industrial basis began in the middle of the 19th century. It was linked with the development of the iron ore and forest industries and helped by the improvements in communications brought about by the building of the railways and the spread of steam navigation. After World War II economic progress was rapid, total production increasing by two-thirds, and consumption by half, within 15 years. Of the gross national product in the early 1960s, two-fifths was contributed by industry and one-fifth by distribution and communications; agriculture, forestry and fishing together contributed less than one-tenth. Private enterprise accounted for three-quarters of the gross national product. The proportion of the total product devoted to investment rose from rather more than one-quarter to more than three-tenths.

Timber and timber products, crops, textiles, and metals are important elements in the Swedish economy: (above) poling logs to mill; (left) raking hay; (below) spinning rayon yarn; (right) hammering steel ingot

### A. PRODUCTION

**1. Agriculture.**—Only one-tenth of the whole area of Sweden is classed as arable or suitable for natural pasture. Of the agricultural land, nine-tenths is privately owned and about one-fifth is held on lease. After 1880 the number of people employed in agriculture steadily decreased, but output was maintained by mechanization. The country is practically self-sufficient in food. Agricultural prices are fixed and supported by Parliament with a view to establishing parity between agricultural and industrial incomes. Farmers are encouraged to abandon small unprofitable farms so that these can be used for forestry or consolidated into larger units. Three-quarters of all holdings, however, are still under 15 ha. (37 ac.). Many farmers, especially in Central and North Sweden, earn part of their living from forestry and fishing. Farmers do almost all their trading and processing through their own cooperatives.

The largest fertile districts are located in Skåne and around the lakes of Central Sweden. Of the arable land, two-fifths is used for grain (chiefly oats, but also barley, wheat, and rye) and a similar area for fodder crops. Continuous plant research has produced improved varieties for Swedish conditions, and the yields in Skåne for barley and sugar beets are among the highest in the world. Milk is the most important animal product, about two-thirds being used for butter and cheese. The number of cows decreased after World War II as some farmers concentrated exclusively on crops. Some raising is important.

**2. Forestry.**—Forests, mainly of pine and spruce, cover about half the surface area of Sweden. The state owns one-fifth of the forests, private individuals one-half, and private companies the remainder. The estimated annual growth comfortably exceeds felling. Cutting and conservation are governed by law, and large-scale research is concentrated on increasing the yield and utilization of the wood.

**3. Fishing.**—The catch of fish by Swedish boats is adequate for domestic needs with a small surplus for export. Besides professional fishermen, nearly as many part-time fishermen combine fishing with forestry or farming, especially on the Baltic. More than half the catch is herring; cod is the next most important. On the west coast about two-thirds of all landings are in the province of Bohuslän, the centre of the canning industry, where a high proportion of professional fishermen operate. Freshwater fishing gives a much smaller catch, but its value is significant.

**4. Mining.**—Lapland contains some of the richest iron ore deposits in the world, estimated at 3,000,000,000 tons. The most important are at Kiruna, where the ore has a content of 60%–70% iron and 1%–2% phosphorus, and where underground mining has replaced open-cast operations. Other deposits of similar quality are at Gällivare and Svappavaara. Most of the Lapland ore is exported through the ice-free Norwegian port of Narvik (linked to Kiruna by rail in 1902), and some from Luleå.

The high-grade ores of Central Sweden have been worked since the 13th century. The domestic iron industry uses ore from the region of Bergslagen, but the deposits at Grängesberg, which have a high phosphorus content, are mainly for export. At Dannemora an ore with a low phosphorus content is mined. Large deposits of sulfide ores are found in the Skellefte region in North Sweden. The most important products are iron pyrites, copper, and lead, with by-products of gold, silver, bismuth, and arsenic.

**5. Fuel and Power.**—Sweden has extensive resources of water power but no worthwhile deposits of oil or coal. During the 1950s the contribution of coal and coke to total energy consumed fell from three-tenths to less than one-tenth, while that of oil rose from one-quarter to one-half; water power contributes one-third of all energy consumed, and Sweden is one of the few countries in which more than nine-tenths of electricity is supplied by water power. The water resources are of the low head type and are un-

evenly distributed. The resources in South and Central Sweden, near the main centres of demand, were developed early, but big rivers such as the Umeålv in North Sweden are now the most important sources. The transmission of large quantities of power to the southern part of the country is made possible by using a very high voltage system. Electricity production increased sixfold between 1939 and the early 1960s, when it was equivalent to nearly half the exploitable resources of water power. About three-fifths of the total output is used in industry. Underground installations account for half the total hydroelectric capacity.

**6. Manufacturing Industries.**—Swedish industry is based on four major native resources—timber, iron ore, water power, and technical skill. There is a strong emphasis on quality. A characteristic feature of Swedish industry is the large number of small and medium-size units; two-thirds of them employ fewer than 21 workers and only one per cent have more than 500 workers. Between 1938 and the early 1960s the volume of industrial production doubled, although the number of workers increased only slightly. This impressive increase in productivity was achieved by a large investment in plant and machinery, the training of a skilled labour force, and intensive research and development.

**Iron and Steel.**—Nearly all the pig iron produced is made with coke. Production of sponge iron (a Swedish development) increased after World War II until it was about one-tenth that of pig iron. Nearly half the steel is produced in electric furnaces and quality steels account for one-quarter of all ingot production.

**Engineering.**—The engineering industries form the largest industrial group. Their output is mainly of high-quality specialized articles. Ball bearings are the most valuable single product. Automobile production expanded rapidly after World War II. Two firms dominate the electrical field; one specializes in heavy equipment for generation, transmission, and utilization of electrical power, the other in telecommunications equipment. Other Swedish products are compressors, munitions, office equipment, and household appliances. Shipbuilding is a major industry, and in the mid-1960s Sweden ranked third in world ship deliveries.

**Forest Industries.**—Timber and wood products were for long the major Swedish exports, but after World War II they took second place to the products of the mining and engineering industries. The forest industries are located mainly on the east coast at the mouths of the large rivers from Gävle to Haparanda. The timber is floated down the rivers to the mills in summer. Pulp accounts for 30% of forest products, followed by paper (27%), sawn timber (22%), and wallboard, prefabricated timber houses, furniture, etc. (21%). Mechanical pulp is used largely for newsprint, whereas cellulose, extracted by both the sulfite and sulfate processes, is used for finer types of paper.

**Chemical Industries.**—Explosives and safety matches have been produced in Sweden since the 19th century. An electrochemical industry produces calcium carbide and ammonia. Ethyl alcohol, used to produce solvents and plastics, is a by-product of the sulfite pulp process. The china and glass industries are noted for their high standard of modern design.

## B. TRADE AND FINANCE

**1. Trade.**—Commerce is an important activity that employs about 500,000 people and accounts for one-eighth of the gross national product. Sweden is very dependent on foreign trade (exports are equivalent to about one-fifth of the gross national product) and the economy is therefore sensitive to fluctuations in world trade. After World War II foreign trade increased at twice the rate of domestic production and, since the terms of trade were increasingly favourable, made a dynamic contribution to the economy. Visible exports were usually rather less than imports, but the foreign earnings of the merchant navy are equivalent to about one-tenth of visible exports. About four-fifths of total trade is with Western European countries, particularly the Federal Republic of Germany, the United Kingdom, and other Scandinavian countries. Raw materials (mainly pulp, timber, and ore) sank from 44% of all exports to 27% during 1953–63, while semimanufactures (mainly paper and cardboard, iron and steel) rose from 20 to 24% and engineering products (mainly nonelectric machines,

ships, and motor vehicles) from 26 to 39%. Sweden's share in the world trade in forest products is 30% for pulp, 13% for sawn timber, and 9% for paper. Imports consist chiefly of raw materials and semifinished goods, machinery, motor vehicles, fuel, and consumer goods.

A special place in domestic distribution is occupied by Kooperativa Förbundet (KF), which started as a wholesale centre for the cooperative societies. It controls flour mills and bakeries, factories for food processing, china, electric bulbs, rubber goods, and fertilizers. It also engages in publishing and insurance. In the early 1960s KF handled one-quarter of the nation's food trade.

**2. Currency and Banking.**—The unit of currency is the krona (plural kronor) of 100 öre (U.S. \$1 = 5.17 kronor). The Bank of Sweden (1668), the oldest existing national bank in the world, is subject to Parliament and not to the government. Besides serving as a central bank for the commercial banks, it sets discount rates, controls the note circulation, and is generally responsible for monetary policy. Ordinary banking transactions are conducted by the 16 commercial banks; the five biggest, of which one is state-owned, control about four-fifths of the business. In the 1960s deposits in the 400 or so savings banks and in the Post Office Savings Bank exceeded slightly those in the commercial banks.

The role of the state in the Swedish economy has steadily expanded; whereas in 1938 the public sector accounted for less than one-sixth of the gross national product, by the early 1960s the proportion had increased to one-quarter. Social welfare, defense, and education are the main items of government expenditure. Almost half the revenue is derived from direct taxes on income and capital at progressive rates (see *Taxation* above).

## C. TRANSPORT AND COMMUNICATIONS

Communications within Sweden have been difficult to develop because of the relatively long distances and the sparse population. The lakes and rivers, used widely from earliest times, were extended by canals in the 19th century, but the economic development of the country was closely linked with the building of the railways, in which the state took an active part from the beginning. An act of 1939 provided for the gradual nationalization of railways that were still privately owned. Since World War II passenger traffic has tended to decrease, and freight traffic to increase. All the main lines are electrified.

Between 1950 and 1960 the annual investment in roads almost doubled, and by the early 1960s there was one car for every five inhabitants. Motorways were being constructed to link the main cities.

The merchant navy grew considerably in the 20th century and comprises about 1,200 ships, having a gross registered tonnage of more than 4,000,000. Roughly two-thirds of the tonnage is engaged in trade between foreign ports, making a significant contribution to the balance of payments.

In 1950 the commercial airlines of Denmark, Norway, and Sweden were merged to form the Scandinavian Airlines System (SAS), which operates a world network. Swedish domestic routes are operated by SAS and AB Linjeflyg, which is owned jointly by SAS and a consortium of Swedish newspaper companies. After World War II domestic passenger traffic expanded more rapidly than international traffic.

There are more telephones in relation to the size of the population in Sweden than in any other country in Europe. The Swedish broadcasting service is partly state-owned, offering two national radio programs and, from 1956, a television service; there is no advertising.

Freedom of the press is guaranteed by the constitution. There are no great newspaper chains, some papers being privately owned and others subsidized by political parties. In all, there are about 170 newspapers and these are well supported in a country where every second inhabitant buys a daily paper. (L. O'C.)

**SWEDENBORG, EMANUEL** (1688-1772), Swedish scientist, philosopher and theologian, one of the greatest and most learned men of his country, was born in Stockholm on Jan. 29, 1688, the second son of Jesper Swedberg, who was later appointed bishop of Skara. The family assumed the name of Swedenborg when it was ennobled in 1719. Emanuel was educated at Uppsala university; and after completing his course there he traveled abroad for five years (1710-14), visiting England, Holland, France and Germany in pursuit of scientific and mechanical knowledge. At that period his chief interests were mathematics and astronomy, and he was cordially received by John Flamsteed and by Edmund Halley. He was anxious to see and to hear Sir Isaac Newton, whose work he studied avidly, but there is no evidence that the two met. Swedenborg's inventive and mechanical genius flowered early, and his plans, practical and otherwise, ranged from a method of finding terrestrial longitude by the moon to new methods of constructing docks and even to tentative suggestions for the submarine and the airplane.

On returning home, Swedenborg began to publish a scientific periodical, *Daedalus hyperboreus* (Uppsala, 1716-18). Charles XII of Sweden was interested in the venture but would provide no funds, and after six issues the periodical was obliged to cease publication. Charles, however, in 1716 appointed Swedenborg assessor extraordinary to the Royal College of Mines, in which office, and later as assessor, he devoted himself for 30 years to the development and improvement of Sweden's metal-mining industry. But he continued to seek fresh knowledge in this and other spheres and from time to time traveled in Europe and in England in pursuit of learning in physics, chemistry, mechanics and philosophy. He had already published in 1718 the first work on algebra in the Swedish language; and in 1721 he published at Amsterdam his *Prodomus principiorum rerum naturalium* in which he offered a geometrical explanation of the phenomena of chemistry and physics. In 1734 he published his *Opera philosophica et mineralia*, 3 vol. (Leipzig), the first volume of which constitutes his *Principia rerum naturalium*. In this work, though without the facts that later scientists have demonstrated, he reached by inductive argument conclusions that are close to the theories of modern nuclear physicists. The first product of the infinite is conceived of as "pure motion" or conatus-to-create, and the subsequent creation is a complex of motion. The atom is composed of vortex particles, but these are compositions of motions more interior. The pattern strongly resembles the pattern of the atom as described in terms of nucleus and electrons. In the same work and from the same general principle Swedenborg suggested the nebular hypothesis to account for the formation of planets.

SWEDENBORG

particular discovery alone. . . . I therefore laid aside my instruments . . . and determined rather to rely on the researches of others than to trust to my own" (introduction to *Oeconomia*). In both works he therefore begins each section with numerous quotations from the accepted experimental anatomists and then proceeds to reason upon them. Gustaf Retzius acknowledged that Swedenborg had been the first to indicate the real nature of the cerebrospinal fluid. In the *Oeconomia* Swedenborg also showed, long before any other physiologist, that the motion of the brain synchronizes with that of the lungs and not with that of the heart and circulatory system; and he discerned the relationship between various regions of the cerebral cortex and corresponding motor regions of the body.

It is, however, in the field of theology that the name of Swedenborg is chiefly known, and the circumstances in which he turned to theological studies have tended to obscure his reputation as a great scientist and philosopher. He asseverates that his entry upon this new study was in response to a divine vision and call; that his spiritual senses were opened so that he might be in the spiritual world as consciously as in this world; and that the long series of exegetical and theological works that proceeded from his pen constituted a revelation from God for a new age of truth and reason in religion. Furthermore, he held that this new revelation of the Lord was what was meant by the second advent. Because of his otherworld experiences Swedenborg has often been regarded as a spiritualist "medium," yet it may be observed that the normal idea of mediumship is reversed, the man being admitted into the spiritual world, not the spirits into the material world. Nor can he properly be classed among the mystics, for in his dry, matter-of-fact accounts of the spiritual world and in his acutely reasoned theology there is little in common with mysticism. His manner is still that of the scientific and philosophic investigator.

Philosophically he had consistently recognized the infinite as the indivisible power and life within all creation, and he had never wavered in his belief that this infinite was God. In his theology he maintains the absolute unity of God in essence and person. A trinity of persons in one God is, he says, an impossibility of thought, but since God is the Divine Man there is necessarily in Him, as in every person, a trinity of love, wisdom and activity; and in God these are infinite and divine. It was this God who came into the world as Jesus Christ for the redemption and salvation of men. The inmost soul of Jesus was the Divine itself, the one God; yet, in order that there might be an intimate contact of God with fallen man, the Divine assumed from Mary a human nature comprising all the planes of human life. But during the course of Jesus' life on earth, by resistance to every possible temptation and by living to their divine fullness the truths of the Word of God, all that was actually from Mary was expelled, and the planes of human nature were "glorified" from the indwelling Divine Soul and became the divine embodiment of that soul. The Trinity is therefore a Trinity in one Person, the Father being the originating Divine itself, the Son the embodiment of that Divine and the Holy Spirit the outflowing activity of the "Divine Human."

In rejecting tripersonalism Swedenborg necessarily rejects the orthodox conceptions of redemption. The redemption of mankind was a deliverance from the domination of evil. The hells, which are the communities of the spirits of evil men in the spiritual world, were aspiring to enforce themselves upon men's minds, destroying their freedom to discern between truth and falsity and therefore between good and evil. By admitting into Himself their temptations and by complete resistance to them, Jesus broke their power; and the inflowing of the Inmost Divine into the human plane thus perfected interposed an eternal and infinitely powerful barrier between the hells and men. The "Divine Human," to which belongs "all power in heaven and on earth," stands forever between man and the forcible imposition of themselves by the hells. Man is thus free to know and obey the truth. His salvation depends on acceptance of and response to divine truth.

Swedenborg, accepting that all creation has its origin in the divine love and wisdom, accepts that all created things are necessarily forms and effects of specific aspects of that love and wisdom and so "correspond," on the material plane, to spiritual realities. The material realm is one of effects whose causes are spiritual and whose purpose is divine. The Scriptures, he says, are written according to this principle of "correspondence," which becomes the key to unlock their spiritual teaching. In *Arcana coelestia*, 8 vol. (London, 1749-56), he presents a detailed interpretation of Genesis and Exodus according to the principle of correspondence; and in the posthumously published *Apocalypsis explicata*, 4 vol. (London, 1785-89), he does the same with the Book of Revelation and incidentally with many other parts of the Scriptures. The theological teaching in his works was collated as a systematic theology in *Vera Christiana Religio* (Amsterdam, 1771). The philosophy of the creation and maintenance of the universe is dealt with in *Sapientia angelica de Divino Amore et de Divina Sapientia* (Amsterdam, 1763) and *Sapientia angelica de Divina Providentia* (Amsterdam, 1764). Swedenborg's best-known work is probably *Heaven and Hell* (*De Coelo et ejus mirabilibus, et de inferno*, London, 1758).

Swedenborg died in London on March 29, 1772, and was buried in the Swedish church. In 1908 the Swedish government had his body removed to Uppsala cathedral.

Swedenborg neither preached nor founded a church. The New Jerusalem Church, founded by a few disciples about 1784, remains small but has branches throughout the world. The Swedenborg society was founded in London in 1810 to publish his works.

C.M.)

**SWEDISH LANGUAGE.** Swedish, one of the Scandinavian languages (*q.v.*), is the national language of Sweden, where only certain minority groups speak other languages (*c.* 30,000 Finnish-speakers in northern Sweden, mostly in Tornedalen on the Finnish frontier, and *c.* 5,000 Lapp-speakers in Lapland). Historically, a distinction is made between East Scandinavian and West Scandinavian languages; Swedish and Danish belong to the former, Norwegian, Icelandic, and Faeroese to the latter. If, however, one considers the present-day relationship between the three continental languages, one is inclined to group Swedish and Norwegian together rather than Swedish and Danish; because Danish later began to diverge by itself, a modern Swede has more difficulty in understanding Danish than Norwegian. Swedish is spoken by about 8 million people, of whom 7½ million live in Sweden, 330,000 in Finland, and an ever-diminishing number in the United States and Canada. Up to World War II an old Swedish-speaking settlement of about 7,500 persons existed on the coast and nearby islands of Estonia. Most of these people now live in Sweden. In Finland, Swedish is officially recognized alongside Finnish.

**History.**—During the first six or seven centuries of the Christian era, practically the same Germanic language, Common Norse, was probably spoken over the whole of Scandinavia. By about 800, dialectal differences of such importance had appeared that

the different Scandinavian languages could be distinguished. The history of the Swedish language is conventionally divided into two main periods: Old Swedish (O.Swed.; *c.* 800-1526) and New Swedish (after 1526).

**The Old Swedish Period.**—The history of the language up to *c.* 1225 is chiefly known from numerous runic inscriptions (*see* RUNE). After this, the Latin alphabet began to be used. Early Old Swedish (usually known as Runic Swedish) has a number of archaic traits: it preserves the old Germanic diphthongs, the four-case system in nominal declension, and almost complete conjugation of verbs according to person. It has not yet developed the indefinite article. The suffixed definite article (*e.g.*, *-in* in O.Swed. *bokin* "the book," originally an enclitic demonstrative pronoun) came into use during this period. Further changes began to take place: *e.g.*, the old diphthongs *ai*, *au*, and *öy* were monophthongized (*ai* > *ei* > long *e*; *au* and *öy* > long *ö*). These changes occurred earlier in southern Sweden than in the more northern areas where monophthongization probably did not occur until the 12th century. In certain peripheral dialects, in Gotland and in various areas of Finland and Norrland, these diphthongs are still preserved.

Especially during the 14th and 15th centuries, radical changes occurred in the language. Various vowel-shifts took place; for example, the long *a*-, *o*-, and *u*-sounds gradually changed to [o:], (at first written *aa* or *o*, but later with a new letter, *ö*), [u:], and [y:]. (For the phonetic symbols used in this article, *see* PHONETICS.) The voiceless dental fricative (originally written *þ*, later *th*) changed to *t*. (The corresponding voiced sound, also written *þ* in the earliest texts, but later *dh*, changed to a stop, *d*, but, on the whole, not until the New Swedish period.) The stops *g* and *k* were affricated before palatal vowels to *gj* and *kj*. The plosive element was later progressively weakened in favour of the fricative. The result of these changes, which were carried to their conclusion during the New Swedish period, is that older *g* and *k* before palatal vowels are now pronounced as [j] (*giva* [ji:va] "give") and [ç] (*kök* [çø:k] "kitchen") respectively. Older *tj* and *kj* have also become [ç] (*tjuv* [çu:v] "thief"), and the appearance of a new sound [ʃ] (also [ʃ], *see* below) for the combinations *sk* + palatal vowel, *skj*, *stj*, and *sj* (*sked* [ʃe:d] "spoon," *skjul* [ʃu:l] "shed," *stjåla* [ʃe:la] "steal," *sjö* [ʃø:] "lake"), is to be connected with these changes. Modern orthography, in the majority of cases, reflects a word's older phonology. All short syllables in stressed position were lengthened, and the accentuation was simplified. A great number of Low German loanwords and derivative elements found their way into the language, especially during the later part of the medieval period, and, while the language of the oldest Swedish literature, written in the Latin alphabet (mainly codes of laws), is very pure Swedish, religious literature shows clear signs of Latin influence, particularly in the syntax.

**The New Swedish Period.**—New Swedish dates from 1526 when the New Testament was printed in Swedish. The written language attained such stability that widespread sound changes rarely occasioned alterations in spelling. Of such extensive changes, mention may be made of the following: in final position, old short *n* was lost (frequently with a change in the preceding vowel: *solen* > *sola* "the sun"). The combinations *rd*, *rt*, *rs*, *rn*, *rl* were assimilated to the alveolar sounds [d], [t], [s], [n], [l]. Certain initial consonant-groups were also simplified: in the combinations *hj*, *lj*, *dj*, *hv* (*hjälpa* "to help," *ljus* "light," *djup* "deep," *hvad* "what") the first consonants were lost. In modern times because of the influence of the written language on the spoken language, the older forms have occasionally been reintroduced, especially those that had survived in certain dialects. Thus, in the Swedish spoken by educated people, only the *-en* ending appears in forms such as *solen*, and not the *-a* ending as in *sola*. In the written language, most changes have occurred in vocabulary and syntax (*see* below).

**Phonology.**—Standard Swedish, as it is spoken in central Sweden, has 9 vowel-phonemes: /a, e, i, o, u, y, ä, å, ö/, and 18 consonant-phonemes: /p, t, k, b, d, g, f, s, ʃ, ç, v, j, m, n, ŋ, l, r, h/. In addition to [d], [t], [s], [n], [l], there is also a series of corresponding alveolar sounds which are phonemically distinct

(cf. *bod* [bu:d] "shed" and *bord* [bu:d] "table"; *vana* [va:na] "custom" and *varna* [va:na] "to warn"). In phonemic descriptions of the language, however, these retroflex sounds are usually regarded as the phonetic result of the combination of the phoneme /r/ + a dental phoneme. Historically, they are the result of the assimilation of *r* + a dental. There are three more written letters in Swedish than in English: these are the vowels *å*, *ä*, and *ö*, which are placed at the end of the alphabet.

As regards the system of 9 vowel- and 18 consonant-phonemes, the following points are worth noting. As a rule, long vowels are qualitatively different from short vowels, most markedly in the case of /a/ and /u/, which, when long, are pronounced [a:], [u:], when short [a], [u]. The vowel-phonemes /o, u, ä/ can also differ qualitatively, viz. /o/: [u:], [u] (written *o*); /u/: [u:], [u] (written *u*); and /ä/: [o:], [o] (written *ä* or *o*). Before alveolar consonants, /ä/ and /ö/ usually have a more open pronunciation: [æ], [œ]. The stops /p, t, k/ are aspirated immediately before a stressed vowel, except in the combinations *sp, st, sk*. The pronunciation of Swedish in Finland, however, totally lacks aspiration, undoubtedly as a result of influence from Finnish. In most of Sweden *r* has dental articulation; in southern Sweden, however, uvular *r* appears. In these areas (and in the pronunciation of Swedish in Finland) *r* + *d, t, s, n*, or *l* is usually pronounced as two separate sounds. As a variant of the normal lateral *l*, a "thick" *l* sometimes appears; this is often formed by a bow-shaped dropping of the tip of the tongue from the roof of the palate. It appears only in certain positions, especially after consonants, and more frequently after back vowels than front (e.g., in *blod* "blood," and *tala* "to speak"). It never replaces lateral *l* when this latter is long, and does so only very exceptionally at the beginning of a word. This "thick" *l* is not found in some areas (for example, in southern Sweden and in Gotland), and is considered by many to be uncultivated pronunciation. The phoneme /ʃ/ can, in any position, appear as [s], although [ʃ] is, perhaps, more usual before a stressed vowel, while [s], appears in other positions.

A stressed syllable is always long, that is to say, it contains either a long vowel, or a short vowel followed either by a long consonant or by a number of consonants. When a stressed vowel loses its stress, it also loses its length: e.g., [\*kal:a] "to call," but [kala hi:t] "to summon." The main stress is usually on the first syllable of a word, as is characteristic of Germanic languages. The numerous exceptions to this rule are mainly found in loanwords (bak'terier "bacteria," matema'tik "mathematics"), in the many words formed with loaned suffixes (lära'rinna "schoolmistress," hal'vera "to halve"), and also in certain words with prefixes (be'tala "to pay," för'klara "to explain"). Every Swedish word is pronounced with one of two different pitch accents, often known as "single tone" and "double tone." These tones can distinguish semantically between two words: e.g., *anden* (single tone; definite form of *and*) "the duck," and \**anden* (double tone; definite form of *ande*) "the spirit." The contrast between these two tones is different in different parts of the country. In central Sweden, disyllabic words with single tone have a rising-falling tone. The single tone is chiefly found in words which are, or were at an earlier stage of the language, monosyllabic: e.g., *hus* "house," and *han'sitter* < *sitr* "he sits." The double tone is found in native words which have, or had earlier, more than one syllable: e.g., *han* \**kallar* "he calls."

**Vocabulary.**—Although Swedish vocabulary is basically native, the language contains a great number of loanwords. Many everyday words are Low German loanwords (*språk* "language," *kort* "short," *fråga* "to ask"). With the Reformation in the 16th century and Sweden's political expansion in the 17th, a number of High German words were imported. From the middle of the 17th to the end of the 18th century, French had the greatest influence. During the 20th century most loanwords have been English. Ever since the 17th century there have been attempts to reduce the foreign element and to exploit native vocabulary. Recently, increasing attention has been paid to Norwegian and Danish, so as to avoid unnecessary divergences between these three languages. Swedish lends itself to extensive formation of new words

by compounding, and occasionally the written language is over-weighted by this practice.

**Morphology.**—Modern Standard Swedish does not formally differentiate between words originally masculine and originally feminine in gender. With regard to words for inanimate objects, a new *genus reale* has superseded masculine and feminine, and one pronoun (*den*) has been substituted for *han* "he" and *hon* "she." Masculine (*pojken, han* "the boy, he"), feminine (*flickan, hon* "the girl, she"), and *genus reale* (*stolen, den* "the stool, it") can be taken together as a *genus utrum*, in contrast to a *genus neutrum* (*huset, det* "the house, it"). However, in contrast to Standard Swedish, most Swedish dialects still have a three-gender system.

Apart from a special genitival form in -s (in both singular and plural), nouns and adjectives have no case inflection. Only personal pronouns have a special object form (cf. *jag* "I" and *mig* "me"). Most nouns form the plural with one of the following endings: -or, -ar, -er, -n. The majority of neuter nouns have the same form in the singular as in the plural. The definite form of a noun is formed by means of an ending: e.g., *sol* "sun," *solen* "the sun," *solar* "suns," *solarna* "the suns"; *hus* "house" and "houses," *huset* "the house," *husen* "the houses." There is, however, an additional definite article, which is used when an adjective precedes a noun in the definite form: e.g., *den lille pojken* "the little boy"; *de stora glasen* "the big glasses." The indefinite form of the adjective differs in ending from the definite form: e.g., *ett stort hus* "a big house," but *det stora huset* "the big house."

As in all Germanic languages, verbs are either strong (*rida, red, ridit* "to ride," "rode," "ridden") or weak (*kalla, kallade, kallat* "to call," "called," "called"). In the spoken language, and normally in the written language, there is no inflection of the verb according to person, but in certain styles of the written language a special plural form is to be found, although this is falling out of use. Besides a compound passive, there is a passive form in -s; thus, present: *skräddaren lagar rocken* "the tailor repairs the coat," becomes *rocken lagas av skräddaren* "the coat is being repaired by the tailor"; and imperfect: *s. lagade r.* becomes *r. lagades av s.*

**Syntax.**—Because of the general lack of case inflection, the word order (subject-predicate-object) is fairly fixed. In principal clauses, inverted word order appears particularly in three cases: in interrogative sentences (*kommer du?* "are you coming?"), when a modification to the predicate precedes the predicate (*nu kommer han* "now he is coming"), and when a subordinate clause precedes the principal clause (*då jag kom, satt han vid bordet* "when I came, he was sitting at the table").

In contrast, for example, to German usage, the complement agrees with its subject in number and gender: e.g., *pojken är stor* "the boy is big," *huset är stort* "the house is big," *pojarna är stora* "the boys are big." The third person possessive pronoun is partly *hans* "his," *hennes* "her," *dess* "its," *deras* "their," and partly the reflexive *sin, sitt* (singular), and *sina* (plural). The first group is used when the possessive pronoun refers to a person or thing other than the subject, the second, reflexive, group when the pronoun refers back to the subject of the sentence.

To express future time, either the present tense of the verb is used, or a compound tense is formed with the auxiliary verb *skall* "shall," "will," or with the verb *komma* "to come": e.g., *jag reser, or jag skall resa, or jag kommer att resa till England nästa år* "I shall go to England next year." A peculiar use of the imperfect appears in the spoken language: e.g., looking at a beautiful flower, one might say: *Det var en vacker blomma* "what a beautiful flower!" (literally "that was a beautiful flower").

During the 20th century, the written language has been considerably influenced by the educated spoken language, especially in sentence structure, choice of words, and, to a certain extent, in inflection. A tendency to reduce the number of clauses in a sentence is to be observed. Of the three negations *icke, ej*, and *inte*, the written language earlier used chiefly *icke* and *ej*, while *inte*, practically the only form used in the spoken language, only appeared in writing in a looser style. By mid-century *inte* had become the prevailing form, even in the written language, while *icke*

and *ej* steadily became less common. An example of the written language's inflectional approximation to the spoken language is to be seen in the tendency to drop the plural form of verbs. Certain features which tend to make the language more ponderous, however, have also appeared, such as the extensive habit of making the verb of the sentence into a noun and, instead, substituting a relatively meaningless verb to act as predicate (e.g., *Den 1 maj skall en sänkning av detaljpriserna äga rum*, literally "On May 1 a reduction of retail prices will take place," appears instead of *Den 1 maj skall detaljpriserna sänkas* "On May 1 retail prices will be reduced"). The facility with which passive forms can be formed by simply adding the ending *-s* has sometimes led to overuse of this form.

**Dialects.**—Swedish dialects are conventionally divided into the following groups: the South Swedish dialects (main province: Skåne); the Göta dialects (main province: Västergötland); the Svea dialects (main province: Uppland); the Norrland dialects (large parts of Norrland); the East Swedish dialects (Swedish as spoken in Finland and Estonia); the Gutnish dialects (Gotland). Particularly archaic features are to be found in the Norrland, East Swedish, and Gutnish dialects, as well as in the local dialects of the northern part of Dalarna. During recent decades, local peculiarities have been superseded more and more by the standard spoken language. The Svea dialects have played the greatest part in the formation of a "Received Standard," but the Göta dialects have also been important.

Gullberg, *Svensk-englisk fackordbok* (a Swedish-English Dictionary of Technical Terms . . .) (1964). (S. C. E. F.)

**SWEDISH LITERATURE.** The first records of literature in Sweden are of more interest to the philologist than to the literary scholar, since the oldest form of Swedish writing is in runes. About 2,400 runic inscriptions survive from the earliest period of Old Swedish (c. A.D. 800–1200); most of them are found in Uppland (eastern Sweden) and date from the 11th and 12th centuries. Cut in stone, and often put into metrical form, they generally commemorate the genealogy and achievements of the dead. The most remarkable stone, the Rök Stone in Östergötland, dates from the 9th century and is unique in the length and interest of its inscriptions, written in seven different types of script (see *RUNE: Scandinavia*). Other notable inscriptions, in the so-called staffless script, have been discovered in the region of Hälsingland. Unfortunately, save for these runes, nothing of the earliest Swedish literature has survived, although it is likely that some kind of literary culture akin to that of Iceland existed (see *ICELANDIC LITERATURE*).

**The Middle Ages (1200–1523).**—Swedish literature proper emerged slowly during the late Middle Ages. After a long

period of linguistic change in Scandinavia (see *SWEDISH LANGUAGE: History*), Old Swedish established itself as a separate language, and the foundations of a native literature were laid in the early 13th century. At about the same time, however, the Christian Church defeated the old religion and introduced Latin as the language of the educated. The importance of Christianity in the cultural development of Sweden is immense, although the new religion prevailed only gradually, and pagan rites existed well into the Middle Ages and in remote districts much longer. Slowly, too, the primitive society of Viking times was replaced by a more complex organization, dominated by the nobility and clergy, patron and providers of literature. Latin eclipsed the vernacular as a literary medium; and this helps explain the derivative nature of medieval Swedish literature. The most remarkable literary document of the period, the *Revelationes* (first published in 1492) of St. Bridget (q.v.; c. 1303–73), illustrates the relationship between the two languages: originally dictated by St. Bridget and written in Swedish, her revelations were immediately translated into Latin by her confessors—later to be retranslated into the vernacular. One more Latin writer of this period attained international recognition, the Dominican monk Petrus de Dacia (c. 1235–89), whose *Vita benedictae virginis Christi Christianae* offers a rare combination of psychological subtlety and mystic fervor.

The oldest extant manuscript in Old Swedish is *Västgötalagen* ("The Law of West Gotland"), part of a native legal code compiled in the 1220s. A number of such local codes survive: e.g., *Östgötalagen* and *Dalalagen*, records of provincial laws privately codified by a magistrate; and lawbooks like *Uppländslagen* (1296) and *Södermannalagen* (1327), compiled on official initiative and ratified by the king. These codes are forceful and full of concrete images; they often use alliteration and a solemn prose rhythm to make their pronouncements more memorable. They offer the happiest examples of the vernacular literature in their age and culminate in King Magnus Eriksson's *Landslag* (c. 1350) and in a similar work, *Um styrlsi kununga och hofdunga* ("On the Conduct of Kings and Princes"), probably written c. 1330 for the guidance of the same ruler.

The poetry of chivalry reached Sweden c. 1300. *Eufemiavisorna* ("The Songs of Euphemia"), written in rhymed doggerel between 1303 and 1312, include a translation of Chrétien de Troyes's *Le Chevalier au lion* (*Yvain*) and a free adaptation of the story of *Floire et Blanchefleur* (see *AUCASSIN AND NICOLETTE*). The spirit of romance (q.v.) is also manifest in many of the anonymous ballads that, though not transcribed until much later, were probably composed in the 14th and 15th centuries. One of the best known, the ballad of *Ebbe Skammellsson*, is of Danish origin and tells a grim story of love and revenge mitigated by traces of chivalrous and Christian ideals. In some of the folk songs (as the ballads, inadequately, used to be called) the new ideals of courtly love (q.v.) are combined with pagan lore of elves, river-gods, and magic mountains, while others are inspired by historical events. Though heterogeneous in quality and style, and in most cases deriving from foreign sources, the ballads form the most accessible and enjoyable genre of Swedish medieval literature.

Apart from the ballads, the late 14th and the 15th centuries are bare of original literature, while translations and adaptations abound. These include versions of books of the Bible, a long doggerel romance of Alexander the Great (*Konung Alexander*, c. 1380), and a political allegory, the poem *Schacktavelslek* ("The Game of Chess"; c. 1465). In the rhymed chronicles, too—e.g., *Erikskrönikan*, *Karlskrönikan*, *Sturekrönikan*, and *Lilla rimkrönikan* (which, together with some minor chronicles, treats events up to 1520)—political interest prevails.

**Reformation and Stormaktstid (1523–1732).**—Two dates mark the beginning of modern Swedish history: 1523—the breach with Denmark and Gustavus I Vasa's accession; 1527—the breach with Rome and the establishment of a national Lutheran Church. The political revolution, which eventually brought Sweden to the position of a European power (*stormakt*), had no considerable effect on literature until a century later, but the Reformation wholly dominated Swedish letters during the 16th century.

The most important literary event of this period is the trans-

lation of the Bible (the New Testament, 1526, and the complete *Gustav Vasas bibel*, 1541), which inaugurated modern Swedish and provided an inexhaustible source of motifs, metaphors, and imagery for poets of subsequent times. Closely involved in the Bible translation were the apostles of the Swedish Reformation, Olaus Petri (1493–1552) and his brother Laurentius (1499–1573), as well as Laurentius Andreae (c. 1480–1552), at one time Gustavus' chancellor. Olaus Petri made other contributions to literature as well. After studying at Wittenberg, he returned to Sweden full of reforming zeal, which won him the king's favour; later his independence and critical spirit nearly cost him his life. His vigorous approach is revealed in his published sermons, hymn translations, catechism, and legal writings; it is shown, too, in *Een Svensk crönica* (published in 1818, in a collection of medieval historical documents), the first historical work in Sweden to be based on critical research. Olaus Petri may also have written the biblical *Tobie comedia* (1550), the first complete extant Swedish play. (See PETRI, OLAUS AND LAURENTIUS.)

As a consequence of the Reformation, two of Sweden's most distinguished scholars of the period were driven into exile. In his *Historia de omnibus gothorum sueonumque regibus* (1555), Johannes Magnus (1488–1544), Roman Catholic archbishop of Uppsala before the Reformation, provided Sweden with a number of valiant and glorious kings until then unknown to critical historians but readily accepted by the political ideologists of *stormaktstiden*. Johannes' brother Olaus Magnus (q.v.; 1490–1557) wrote the first geographical and ethnographical account of Scandinavia, *Historia de gentibus septentrionalibus* (1555), in which vivid description and accurate observation are mingled with nostalgic dreams of a hyperborean Atlantis.

Meanwhile academic learning was in decline. The University of Uppsala (founded 1477) closed in 1515 because of political unrest. It was not revived until late in the 16th century and became a focus of learning and letters only in the 17th century. Associated with it were Johannes Rudbeckius (1581–1646), one of the first Swedish educators, and Johannes Messenius (c. 1579–1636), who wrote several mythical-historical plays, such as *Disa* (1611) and *Signill* (1612). Although formless and crude, these plays enjoyed great popularity, as did Magnus Olai Asterophorus' *Tisbe* (performed 1610), the first nondidactic drama in Sweden.

In the first half of the 17th century, literature remained limited in scope and quantity. Some Latin poetry, the sermons of Rudbeckius, and a handful of plays are worth recording. A unique contribution, however, was made by the vagrant adventurer Lars Wivallius (q.v.; 1605–69), whose lyrics, many of them written in prison, reveal a feeling for nature new to Swedish poetry. With the intervention in the Thirty Years' War and the ensuing military triumphs, Sweden established itself as a European power. This led to a great development of national pride and culture, as is revealed in the literature of this epoch. The outstanding work is the allegorical epic *Hercules* (1658) by Georg Stiernhielm (q.v.; 1598–1672), written in vigorous hexameters and reflecting the social and political problems of the time, as well as the philosophical and religious views of its author. Stiernhielm was the greatest literary figure of the 17th century and was often in attendance at

the court of Queen Christina (q.v.), an outstanding patroness of the arts. His followers included the two brothers Columbus, one of whom, Samuel (1642–79), wrote *Odae sueticae* (1674) and the prose *Mål-roo eller Roo-mål* (published in 1856), a charming collection of anecdotes that illumine Stiernhielm's character. A rival to Stiernhielm was the unidentified "Skogekär Bergbo," whose *Wenerid* (1680) is the first sonnet cycle in Swedish. Another unsolved problem of this period is the authorship of the epithalamium *Bröllopsbeswärs ihugkommelse* (first published in the early 19th century), a realistic poem long attributed to Stiernhielm. Several of Stiernhielm's admirers, including Urban Hiärne (1641–1724), formed a coterie at Uppsala in the 1660s. Hiärne led a troupe of student actors who in 1665 performed his play *Rosimunda* before the young Charles XI. He also wrote lyrics and the prose pastoral *Stratonice* (1666–68), the first "psychological" narrative in Swedish.

Stiernhielm aimed at an integration of Sweden's cultural heritage with the accepted ideals of continental classicism. His

*cules* is a hexameter epic, but it is rhymed, sometimes even alliterated, and full of old Swedish words that he was eager to revive. Columbus also demanded a more vigorous, flexible language for prose and poetry, as did "Skogekär Bergbo" in *Thet svenska språkets klagemål* ("The Lament of the Swedish Language"; 1658). National pride and religious feeling are combined in the works of the bishops Haqvin Spegel (1645-1714) and Jesper Swedberg (1653-1735), father of the Swedish mystic Emanuel Swedenborg. Both were hymn writers and ardent philologists. Spegel, as well as writing a religious epic (*Guds verk och hvila*, 1685), contributed to Swedberg's new hymnbook of 1695, which became the poetry book of the Swedish people and was, like *Gustav Vasas bibel*, of lasting influence. Even Lasse Lucidor (*q.v.*; 1638-74) was represented in it. Lucidor, who called himself *den olycklige* ("the unhappy one"), gave intense lyric expression to the contrasting moods of the period: in his love songs and, above all, in his drinking songs, he is as pagan and reckless as he is repentant and devout in his hymns and funeral poems.

At Uppsala, meanwhile, the scholar Petrus Lagerlöf (1648-99) worked on poetics and attempted to impose purer classical standards, and Olaus Verelius (1618-82) edited and translated Icelandic sagas. Olaus Rudbeck (1630-1702), a man of vast energy and learning, became interested in Verelius' work and enthusiastically developed the theory that Sweden was the lost Atlantis and had been the cradle of Western civilization. These theories he launched in a massive work, *Atlant eller Manhem* (1679-1702), deliberately written in Swedish to prove that the language was suited to scientific purposes. The work, translated into Latin as *Atlantica*, attained European fame.

Baroque and classicistic tendencies run parallel in late 17th-century Swedish literature. An exponent of the marinist style (see MARINO, GIAMBATTISTA) was Gunno Eurelius (ennobled as Dahlstierna; 1661-1709), whose elaborate epic *Kunga skald* was written for King Charles XI's funeral in 1697 in the manner of Marino's *Adone* (1623). Simpler in style is Johan Rumi (1679-1713), who expresses a Christian stoicism of the kind found among the Swedish people during the disastrous early decades of the 18th century. Jacob Frese (1691-1729) is a gentler and more intimate poet; his lyrics and hymns contain some of the emotional pietism that became a feature of 18th-century thought.

**Classicism and Enlightenment (1732-1809).**—After the death of Charles XII (1718) and the collapse of his empire, a more utilitarian attitude to life and letters gradually developed. Olof von Dalin (*q.v.*; 1708-63) is the outstanding popularizer of the new ideas of the French and English Enlightenment. Educated at the University of Lund (founded 1668), he later went to Stockholm and began to publish, anonymously, *Then swänska Argus* (1732-34), the weekly periodical modeled on those of the English Joseph Addison and the Dutch Justus van Effen, and one of the first serious journalistic ventures in Sweden. Dalin's publication marks the beginning of a new era in Swedish letters: orthodoxy gives way to skepticism and enlightenment, Baroque ideals to classicism, and German influence to English and French; and the middle class begins, gradually, to take over the function of chief upholder of literature, though several of the poets of the period were noblemen. In *Argus* Dalin ridiculed the foibles of the capital in forceful, supple prose, and in *Sagan om hästen* ("The Story of the Horse"; 1740) he showed himself a master of allegorical satire. As a court poet and favourite, and as a member of Queen Lovisa's Vitterhetsakademi (Academy of Literature), he composed elegant occasional verses. He also wrote some pseudoclassical plays that, like many dramatic ventures of the early and mid-18th century, are academic and lifeless. An exception is *Swenska språthöken* ("The Swedish Fop"; 1740), the comedy by Count Carl Gyllenborg (1679-1746).

With the second phase of the Enlightenment, marked by the influence of Rousseau, are associated Hedvig Charlotta Nordenflycht (*q.v.*; 1718-63), Gustav Philip Creutz (*q.v.*; 1731-85), and Gustaf Fredrik Gyllenborg (*q.v.*; 1731-1808). In *Den sorgande turturdufvan* ("The Sorrowing Turtledove"; 1743), Fru Nordenflycht lamented the death of her husband in emotional and highly personal lyrics. Creutz was a more sophisticated personality. He

("My Son on the Galleon"; 1781), a humorous, realistic diary of voyages on an East Indiaman. The only two 18th-century Swedish writers of European reputation were scientists: Carl von Linné (Linnaeus, *q.v.*; 1707-78) and the mystic Emanuel Swedenborg (*q.v.*; 1688-1772). Linné's work at Uppsala much enhanced the prestige of the university, and his travel books are remarkable for their understanding of nature and freshness of style.

The Gustavian period takes its name from the brilliant Gustavus III (1746-92), in all respects a royal patron of art and letters. At his court he collected the best writers of the time, and by founding the Swedish Academy (1786) he gave them official status. He was especially interested in drama and opera; thanks to his patronage, a proper theatrical tradition was begun, and the leading authors—often against their will—had to produce texts for performance. Gustavus himself sketched out some of these works, the best of which is the historic opera *Gustaf Vasa* (1786), the happy result of the collaboration between Johan Henric Kellgren (*q.v.*; 1751-95) and the composer J. G. Naumann. Kellgren was the great academic poet and the arbiter of taste, ruling that comedies should be modeled on those of the French, and that tragedies should be pseudoclassical. Beginning as a rationalist and satirist after the fashion of Voltaire, he reluctantly accepted pre-Romantic ideas in later life. In *Stockholmsposten*, the main organ of literary opinion in the capital, Kellgren used his polemical wit against Thomas Thorild (*q.v.*; 1759-1808), the truculent champion of individual genius, who wrote a long poem, *Passionerna* (1785) celebrating Ossian as the king of poets, but who is chiefly remembered for his polemical prose. After Kellgren's death the controversy was carried on by Carl Gustaf af Leopold (*q.v.*; 1756-1829), who still imposed pseudoclassical standards on the academy and applied them in his rhetorical odes and tragedies. Johan Gabriel Oxenstierna (*q.v.*; 1750-1818) did his most original work in 1770-74 while a diplomat in Vienna; *Skördarne* ("Harvests"; 1796) and *Ode till Camilla* (first published in the 19th century) reveal an elegiac, pre-Romantic feeling for the beauty of nature. Bengt Lidner (*q.v.*; 1757-93) was a follower of Thorild but showed much more poetic inspiration in his play *Erik XIV* (1782), his opera *Medea* (1784)—both lyrical rather than dramatic in tone—and in his most successful work, the ode *Grefvinnan Spastoras död* (1783). The influence of both Milton and the Bible may be traced in his use of language.

Carl Michael Bellman (*q.v.*; 1740-95) stands apart from the conflicting ideals of the time. A poet and musician, he fused his gifts in the lyrics of *Fredmans epistlar* (1790) and *Fredmans sånger* (1791). His combination of stylized realism with humor and the most delicate sense of language and rhythm is unique in

wrote little, devoting his life after 1763 to diplomacy, but his few writings, of which the pastoral epyllion *Atis och Camilla* (1762) is the most important, reveal a mastery of form and versification. Creutz's view of life was Epicurean, while his friend Gyllenborg was a stern Stoic. Though lacking the formal elegance of Creutz's poetry, Gyllenborg's best poems, "Veridsföraktaren" (1762) and "Vinterkväde" (1759), have nobility and feeling for nature.

Prose—particularly the novel—developed more slowly. The first genuine novel was *Adalrik och Gjöthildas afwentyr* (1742-44), by Jacob Mörk (1714-63) and Anders Törngren (b. 1714), showing the influence of the Icelandic sagas and of Madeleine de Scudéry. But the raciest prose of this period is found in Jacob Wallenberg's *Min son på galejon*

Swedish. He is the greatest Swedish lyricist of the 18th century. The dissertation *Om upplysning* ("On Enlightenment"; 1793) by Nils von Rosenstein (1752-1824), the first secretary of the Swedish Academy, nobly expresses the highest ideals of the Gustavian epoch; and various memoirs, by G. J. Adlerbeth, G. J. Ehrensvärd, Count Fredrik Axel von Fersen, Duchess Hedvig Elizabeth Charlotte, and others, evoke the witty but artificial atmosphere of Gustavus III's court and illustrate the development of prose. Gustavus IV (1778-1837), did not encourage literature; however, the energetic Anna Maria Lenngren (q.v.; 1754-1817), wife of the editor of *Stockholmsposten*, wrote some of her best verse satires between 1795 and 1800, many of her anonymous shafts being aimed at aristocratic foibles. The sentimental idylls of Frans Mikael Franzén (q.v.; 1772-1847) also belong to these years; they are full of pre-Romantic idealism imbibed from German and English sources and later toned down under pressure from the academy.

**The Romantic Movement (1809-1830).**—The loss of Finland to Russia in 1809, the deposition of the king, and the new constitution of 1809 all greatly affected Swedish literature, for out of them an ardent national spirit emerged as one of the motifs of Swedish Romanticism. The teaching at Uppsala of Benjamin Höijer (1767-1812), admirer of Immanuel Kant and F. W. J. von Schelling, laid the basis for the idealism that soon became the core of Swedish Romanticism. The impact of Schiller, Goethe, and the German Romantics on the Swedish literature of the early 19th century was overwhelming, and Swedish Romanticism became as much dominated by German culture as the previous era had been by French. Student societies formed the focuses of the new movement, and the periodicals issued by them and their adherents—e.g., *Polyfem* (1809-12) and *Phosphoros* (1810-13)—attacked the academy. *Phosphoros*, from which the group called the Fosforister (Phosphorists) took their name, played an especially important initial role in the controversy between the old school and the new during 1810-20. Per Daniel Amadeus Atterbom (q.v.; 1790-1855), the most gifted of the Fosforister, first revealed his talents in his verse *Prolog* (1810) to *Phosphoros*; Vilhelm Fredrik Palmblad (1788-1852), publisher and prose writer, led the practical polemics at Uppsala; Lorenzo Hammar-sköld (1785-1827), with Johan Christoffer Askelöf (1787-1848) and Clas Livijn (1781-1844), carried on the fray at Stockholm; while Johan David Valerius (1776-1852) and P. A. Wallmark (1777-1858) championed the old school, as for a time did Johan Olof Wallin (1779-1839), the greatest hymn writer of the century and the chief contributor to the new official hymnary of 1819.

Meanwhile another society, Götiska förbundet, had been founded in Stockholm in 1811, with the object of raising the moral tone of society by study of the heroic, "Gothic" past, as expressed in pre-Christian mythology (see GERMANIC MYTHOLOGY AND HEROIC LEGENDS). Erik Gustaf Geijer (q.v.; 1783-1847), one of the founders, suggested the publication of a periodical, and the first issue of *Iduna* (1811) consisted largely of his own poems; e.g., "Vikingen" and "Odalbonden." Most of Geijer's poetry, including the first Swedish translation of Shakespeare's *Macbeth*, was written before 1816. Esaias Tegnér (q.v.; 1782-1846) also contributed to *Iduna*, though he refused to engage in literary controversy. It was Tegnér, however, who wrote the most popular poem of this period, *Frithiofs saga* (1825), an epic based on an old Norse theme. For Tegnér, as well as for Geijer, the poetic revival of the Gothic past was not only a matter of national feeling and moral concern. In the old Northern mythology they seemed to discern the same eternal patterns as in Greek mythology and Romantic metaphysics: religion, philosophy, and poetry appeared to be one and the same. In the poems "Skaldens morzonpsalm" and "Sång till solen," Tegnér pictures himself as a divinely inspired seer, and in the last canto of *Frithiofs saga*, written in the metre of Greek tragedy (the iamb), the myths of Christ and Balder (q.v.) are fused in the spirit of German idealism. However, clarity of thought and formal perfection were indispensable standards of criticism with Tegnér, and, hence, he often sided with the academicians in their struggle against Romantic obscurantism and formal innovations.

Several of the leading Romantics were learned men—Tegnér, Geijer, and Atterbom, for instance, were all university professors—and they often strove to embody a philosophical system, or an interpretation of history, in their poetic writings. The most ambitious attempt of this kind was Atterbom's *Lycksalighetens ö* ("The Isle of Bliss"; 1824-27), a somewhat shapeless verse drama dealing, on the literal level, with the love and adventures of the legendary Prince Astolf but, allegorically, with the history of poetry as an illustration of man's alienation from the Divine.

The greatest poet of the Romantic movement in Sweden is perhaps Erik Johan Stagnelius (q.v.; 1793-1823). Ugly, sickly, and, toward the end of his life, pitifully debauched, he held aloof from the schools and coteries of the day and created a poetic world of his own. The recurrent theme in *Liljor i Saron* (1821), a collection of "theosophical" poems, is the lament of Anima, the human soul, imprisoned in a world of darkness and sin. Stagnelius also wrote the only successful classical drama in Swedish, *Bacchanterna* (1822), celebrating the death and transfiguration of Orpheus.

A number of minor Romantic writers should be mentioned—e.g., Adolf Törneros (1794-1839); Per Elgström (1781-1810); Samuel Hedborn (1783-1849), author of several attractive hymns and ballads and of an autobiography, *Minne och poesi* (1835); Arvid August Afzelius (1785-1871), collector of folk songs (*Svenska folkvisor från forntiden*, 1814-16); and Erik Sjöberg ("Vitalis," 1794-1828).

**The Coming of Realism (1830-1880).**—The most complex personality among the later Romantics was Carl Jonas Love Almqvist (q.v.; 1793-1866), who combined an extravagant imagination, as in his novel *Drottningens juvelsmycke* (1834), with the realism that is increasingly prominent in his works after 1836. Almqvist, a master of prose style, was at his best in the long short story, or *novell*; of his works in this genre, *Det går an* (1839), an outspoken attack on marriage, foreshadows Strindberg's method of raising problems for debate.

Meanwhile the realistic novel had advanced. Fredrik Cederborg (1784-1835) wrote *Uno von Trasenborg* (1809-10) and *Ottar Tralling* (1810-18), lighthearted satires on life and manners. But the novel as an accepted genre was really established by Fredrika Bremer (q.v.; 1801-65), whose "sketches from ordinary life" appeared from 1828. Her novels, e.g., *Grammarne* (1837), have dated considerably but were formerly very popular in both Europe and the United States. Sophie von Knorring (1797-1848) wrote novels principally about aristocratic families, and the very popular Emilie Flygare-Carlén (1807-92) produced a long series of stories, including *Rosen på Tistelön* (1842), usually dealing with life on the Swedish west coast.

Realism, then, made only slow headway, in spite of the social consciousness of the liberal paper *Aftonbladet* and the example of the great Finnish-Swedish poet Johan Ludvig Runeberg (q.v.; 1804-77). The literature of the 1840s and 1850s is mainly an aftermath of Romanticism, though the critic Bernhard Elis Malmström (1816-65) was ostensibly an opponent of the movement—and even his work showed Romantic influence. His elegy *Angelica* (1840) has affinities with the graceful but insipid poetry of his contemporary Carl Vilhelm Böttiger (1807-78) and the older Karl August Nicander (1799-1839). There is a fresher feeling about Gunnar Wennerberg's *Ghutmöre* (1849-51), songs about Uppsala student life in the 1840s, but there is nothing new in them. The movement known as Scandinavism produced a good deal of verse: Carl Vilhelm August Strandberg ("Talis Quahs," 1818-77), the fieriest poet of this type, later made excellent translations from Byron. Oskar Patrik Sturzen-Becker ("Orvar Odd," 1811-69) was a versatile writer with talents in verse and the short story. Popular reading was provided by August Blanche (1811-68), particularly in the successful *Bilder ur verkligheten* (1863-65), short stories depicting Stockholm life with humour and vivacity. He also wrote popular dramas. Frans Hedberg (1828-1908) held the stage at the Royal Theatre with pompous historical plays, such as *Bröllopet på Ulfåsa* (1865). The quasi-historical novels of Magnus Jacob Crusenstolpe (1795-1865) were much appreciated in their day.

Poetic realism became the official program of Signatur-poeterna

(the "pseudonym poets"), a small group of the 1860s, including Carl David af Wirsén (1842–1912), Edvard Bäckström (1841–86), Pontus Wikner (1837–88), and Carl Snoilsky (q.v.; 1841–1903). However, only Snoilsky had the temperament and poetic gift needed to carry out the program. Some of his best work is found in *Dikter* (1869) and *Sonetter* (1871). Meanwhile Wirsén had established himself as the conservative literary critic, and from his post as secretary of the Swedish Academy he launched formidable opposition against all innovators, including Snoilsky. Viktor Rydberg (q.v.; 1828–95) exemplifies this rather uneasy transition from idealism to Naturalism even more patently than does Snoilsky. Novelist, poet, and critic, he began as a radical journalist and ended as a professor and author of philosophical poems (*Dikter*, 1882; *Nya dikter*, 1891). His most important early work was the ideological novel *Den siste athenaren* (1859), and his treatise *Bibels lära om Kristus* (1862) had considerable influence through its attack on the narrow orthodoxy of the Swedish Church and prepared the way for scientific rationalism.

**Naturalism and Neoromanticism (1880–1900).**—Four influences combined to free Swedish literature from its petrifying conventions: English thought in the writings of Charles Darwin, Herbert Spencer, and J. S. Mill; French Naturalism as taught and practised by Émile Zola; the drama of the Norwegians Henrik Ibsen and B. Bjørnson; and the criticism of Georg Brandes. Modern Swedish literature begins with the work of August Strindberg (q.v.; 1849–1912), for the modern drama dates from his *Mäster Olof* (1872) and the modern novel from his *Röda rummet* (1879; *The Red Room*). By his originality, his mastery of prose and dialogue, his great energy, and the influence of his work and personality on Swedish, not to say European, literature, he is by far the greatest writer Sweden has produced.

Strindberg overshadows all other writers of the 1880s. Gustaf af Geijerstam (1858–1909), author of *Erik Grane* (1885) and of other novels and short stories, longed to lead his age but could not do so. Anne Charlotte Edgren-Leffler (1849–92) wrote a number of stories, collected in *Ur lifvet* ("From Life"; 1882–83), in which she satirized conventions adversely affecting women. The more gifted Victoria Benedictsson ("Ernst Ahlgren," 1850–88) died—by her own hand—before she had fulfilled her promise; she, too, but more boldly, was concerned with the position of women in society. Her stories (*Från Skåne*, 1884) have lasted better than her novels (*Pengar*, 1885, and *Fru Marianne*, 1887) and reveal how much regional characterization had entered into the new style of literature. With her was associated Axel Lundegård (1861–1930), who soon turned his talents to the historical novel. Regional poetry was written by Albert Ullrik Bååth (1853–1912) of Skåne, whose work was surpassed in beauty and originality by the work of another Skåne poet, Ola Hansson (q.v.; 1860–1925), also a novelist and critic. Hansson's early poems (*Notturmo*, 1885) and his prose sketches (*Sensitiva amorosa*, 1887) reveal a boldness in imagery and the interest in psychological nuances more typical of the next decade.

The reaction against utilitarianism and Naturalism was begun in 1888 by Verner von Heidenstam (q.v.; 1859–1940) with his volume of verse *Vallfart och vandringsår* (1888). His later poetry and historical tales won him the Nobel Prize for literature in 1916. Although much of his work now seems precious and dated, his short contemplative lyrics are very fine. Oscar Levertin (1862–1906), stimulated by his friend Heidenstam's example, wrote poetry full of rich colours and the lore of the past, showing his affinity with the pre-Raphaelites, his knowledge of French Symbolism, and his awareness of his own Jewish heritage. His criticism, published in *Svenska dagbladet* and elsewhere, did much to mold contemporary taste. Gustaf Fröding (q.v.; 1860–1911), too, was encouraged by Heidenstam; the title of his first volume of verse, *Guitarr och dragharmonika* (1891; *Guitar and Concertina*), shows the two different strains in the poet, melancholy and gay, which constantly intermingle and out of which he wrested such original music. Despite the threat of madness, he managed to publish four more collections of poems before his reason finally gave way in 1898, by which time he had established himself as one of the greatest Swedish lyric poets. With Fröding, who was from

Värmland, regionalism entered into Neoromantic poetry, and with the work of Erik Axel Karlfeldt (q.v.; 1864–1931) the province of Dalarna came into its own. Karlfeldt's mature poetry, such as *Fridolins visor* (1898) and *Hösthorn* (1927), reveals his individual strength and the richness of orchestration that he alone could give to Swedish and won him the Nobel Prize for literature in 1931.

Meanwhile Selma Lagerlöf (q.v.; 1858–1940) had developed the prose tale. Her long series of novels and short stories, beginning with *Gösta Berlings saga* (1891), reached an international public; she was, indeed, the first Swede to win the Nobel Prize for literature (1909). She often used old Värmland tales for material, though one of her best novels, *Jerusalem I* (1901), is set in Dalarna. Per Hallström (1866–1960) is a more skilful writer of short stories than of novels; like Lagerlöf, he did his significant work before 1910. Romantic, too, in his love for the skerries (rocky isles) was Albert Engström (1869–1940), storywriter, cartoonist, founder of the popular humorous paper *Strix*, and one of the most beloved of Swedish writers.

**The 20th Century.**—The *fin de siècle* and the early years of the 20th century were a period of decadence and pessimism in Swedish literature, as in European literature in general. Representative of this mood are Hjalmar Söderberg (q.v.; 1869–1941) and Bo Bergman (q.v.; 1869– ). Both had links with the rationalism of the 1880s and the aestheticism of the 1890s, yet both stand apart from the Neoromantics. Both, like Strindberg, loved Stockholm, which perpetually recurs as the setting of their works. Söderberg's forte was the short story (*Historietter*, 1898), in which his psychological subtlety and irony are happily combined and in which, as in his novels *Martin Bircks ungdom* (1901) and *Doktor Glas* (1905), he appears as a master of Swedish prose. Bergman also produced memorable short stories, but his real medium was the lyric; he developed and refined his talent in a series of collections from *Marionetterna* (1903) to *Riket* (1944).

From the beginning of the 20th century, industrialization, the growth of the press, and the spread of education increasingly influenced letters. The reading public continued to grow, and the volume of writing similarly increased, a marked feature being the development of the novel, with which are associated Gustaf Hellström (1882–1953), Ludvig Nordström (q.v.; 1882–1942), Elin Wägnér (1882–1949), and Sigfrid Siwertz (1882– ). Hellström's work as journalist took him to other European countries and to the United States, and long residence in England greatly influenced him. His irony and careful realistic detail emerge in his best-known novel, *Snörmakare Lekholm för en ide* (1927; *Lacemaker Lekholm Has an Idea*), set in a small provincial town. Siwertz is a more elegant stylist—like so many Swedes he began as a lyricist—and a decisive influence upon him was the philosophy of Henri Bergson (q.v.), reflected in *En Fiancé* (1914). His weightiest work is the family saga *Selams* (1920; *Downstream*), a novel of Stockholm during World War I. Nordström came from Norrland, and his birthplace—Härnösand—is perpetuated in his work as "Öbacka." Overflowing with vitality and gifted with keen but grotesque humour, he did some of his best work in *Landsortsbohème* (1911) and *Planeten Markottan* (1937), but his most satisfying productions are the short stories in *Fiskare* (1907), *Öbackabor* (1921), etc. Elin Wägnér was an ardent pacifist and feminist; her most powerful work is the peasant novel *Åsa-Hanna* (1918).

The outstanding novelist of the 1920s is Hjalmar Bergman (q.v.; 1883–1931). Gifted with a fantastically vivid imagination and restlessly energetic, Bergman wrote a long series of stories, many of which are set in "Wadköping" (his native Örebro) and its surroundings, others in Italy. In *Loewenhistorier* (1913), as in other works, Bergman depicts an irrational, impulsive, unsuccessful hero; in *Farmor och Vår Herre* (1921; *Thy Rod and Thy Staff*), he portrays one of the dominating female personalities who fascinate him. The satire *Markurells i Wadköping* (1919; *God's Orchard*) and *Swedenhielms* (1925), one of the few existing Swedish comedies, are his most widely known works.

Meanwhile the "proletarian" novel had been developed—always by working-class writers—by Gustav Hedenvind-Eriksson

(1880–1901–), Martin Koch (1882–1940), and Ivar Lo-Johansson (1901–), who is particularly concerned with the miseries of *statorens* ("farm labourer's") life. There is particularly harsh and telling criticism of working-class conditions in the Lars Hård series and other stories by Jan Fridegård (1897–). Vilhelm Moberg (1898–) wrote both realistic and historical novels of peasant life but achieved his greatest success with the broad prose epic about a group of Swedish emigrants to North America, *Utvandrarna* (1949; *The Emigrants*). Noteworthy contributions to the development of the Swedish autobiographical novel were made by two self-educated members of the proletariat: Eyvind Johnson (1900–), with *Romanen om Olof* (1934–37), and Harry Martinson (see below), with *Nässlorna blomma* (1935) and *Vägen ut* (1936). The autobiographical element is evident, too, in the works of Agnes von Krusenstjerna (1894–1940). In her novel cycles, e.g., the *Tony* trilogy (1922–26) and the *Fröknarna* von Pahlen series (1930–35), she describes her own aristocratic and upper-middle-class environment and analyzes a degenerate and perverted psychology.

The greatest Swedish writer of the 20th century is perhaps Pär Lagerkvist (q.v.; 1891–), who won the Nobel Prize for literature in 1951. In his youth a bold formal innovator, he later developed an admirably pure prose style, as in the allegorical novel *Dvärgen* (1944; *The Dwarf*). Expressionistic in style are his collections of poems, e.g., *Ångest* (1916), and his early plays, e.g., *Himlens hemlighet* (1919), reflecting the dark years of World War I. Lagerkvist's writings during the 1920s include an autobiographical novel and love poetry, but the dominant theme throughout his work is a search for vital, often outspokenly religious, values.

Several of the best Swedish writers of the 20th century have been connected with the development of lyric poetry. Vilhelm Ekelund (1880–1949) found his ideals in the classical tradition, while Anders Österling (1884–) was more of a poetic realist. The ballads of Dan Andersson (1888–1920) became very popular, as did the songs of *Fridas bok* (1922) by Birger Sjöberg (1885–1929). In Sjöberg's later work the formal disintegration characteristic of so much modern poetry becomes noticeable, though most of the poets of the 1920s and '30s were still traditionalists; e.g., Karin Boye (q.v.; 1900–41), Bertil Malmberg (1889–1958), Johannes Edfelt (1904–), and Hjalmar Gullberg (1898–1961). In Gullberg's later poetry, however, the light ironical style of his earlier works is replaced by a passionate upsurge not always capable of being expressed in traditional forms.

About 1930 a group of five "primitivistic" writers was formed, of whom Harry Martinson (1904–) later developed into one of the finest and boldest lyricists of the century. Sensuous imagery and an intimate feeling for nature characterize much of his work. An attempt to revive the verse epic is his *Aniara* (1956), the symbolical story of a voyage of a spaceship, which was turned into an opera by K.-B. Blomdahl in 1959.

Among the forerunners of lyric modernism in Sweden were Lagerkvist and Sjöberg, but it was not until the early 1940s that formal experimentation became part of the program of a group of poets, the so-called generation of the '40s (*fjortitalisterna*). Influenced by the poetic technique of such writers as Ezra Pound and T. S. Eliot, Gunnar Ekelöf (1907–), Erik Lindegren (1910–), and Karl Vennberg (1910–) were among the chief champions of lyric modernism. Lindegren's *Mannen utan väg* ("The Man Without a Way"; 1942) is typical of this generation's anguished search for a meaning in life. Ekelöf began as a Surrealist and then inclined toward Romanticism for a period, finally to find his own highly personal style in *Färjesång* (1941) and *Non serviam* (1945), which include some of the finest poems in the Swedish language. In his later works he turns against all the accepted ideas of poetic beauty and lyric expression, though the *Mölna-elegi* (1960) is still haunted by romantic echoes.

**SWEELINCK, JAN PIETERSZON** (1562–1621), Dutch organist and composer, one of the principal figures in the development of organ music before J. S. Bach. Born in April 1562 in Amsterdam, he succeeded his father as organist of the Oude Kerk (Old Church), Amsterdam, about 1580, and remained in this post until his death. He married in 1590, and his wife bore him seven children. He seems never to have left the Low Countries and to have traveled only to Rotterdam and Antwerp. He died in Amsterdam on Oct. 16, 1621.

Although he composed much sacred and secular vocal music, including the *Chansons à 5*, the *Cantiones sacrae*, and settings of the Psalms, in the polyphonic traditions of France and the Netherlands, Sweelinck was chiefly known as an organist and keyboard composer. His keyboard music includes chorale variations, remarkable for their double and triple counterpoint; toccatas and fantasias showing the influence of the Venetian organ school; and sets of variations on secular tunes.

Sweelinck's fantasias are among the first works for organ to consist of contrapuntal variations on a single theme subjected to augmentation, diminution, and changes of rhythm. For his secular variations, Sweelinck drew upon popular tunes of several European countries. The set of variations on *Mein junges Leben hat ein End* is perhaps his best-known work.

It is possible that Sweelinck met the English composers John Bull and Peter Philips during their visits to the Low Countries; Bull's "Fantasia on a Theme of Sweelinck" was the tribute of one keyboard virtuoso to another. Sweelinck's keyboard playing was widely known, and his organ pupils included the German composers Samuel Scheidt and Heinrich Scheidemann. Scheidemann's pupil J. A. Reinken was to hand on this tradition of organ playing to Dietrich Buxtehude. Sweelinck's works, edited by Max Seifert, were published by the Vereeniging voor Nederlandse Muziekgeschiedenis in 12 volumes (1895–1903). The first volume, containing his instrumental works, was revised in 1943.

See H. Antcliffe, "J. P. Sweelinck," *Proceedings of the Musical Association*, vol. 61 (1934); R. L. Tusler, *The Organ Music of Jan Pieterszoon Sweelinck* (1958). (C. P. Co.)

**SWEET ALYSSUM** (*Lobularia maritima*), the ever-popular little white- or violet-flowered, fragrant, half-hardy perennial of the mustard family that is usually grown as an annual. It is widespread on the ground, with branches rising 6 to 12 in., and numerous small flowers distributed in lengthening clusters. It occurs in both large and small forms, some with white-edged leaves and some with double flowers. It is an excellent edging plant that blooms over a long season. (J. M. Bl.)

**SWEETBREAD**, a popular term for certain glands of animals, particularly when used as food; these are usually the pancreas, called stomach sweetbread by butchers, and the thymus, or neck sweetbread. The term is also sometimes used to include the salivary and lymphatic glands. See PANCREAS; THYMUS.

**SWEET CLOVER** (*Melilot*), a sweet-smelling weedy herb of the pea family (*Leguminosae*) grown for forage, soil improvement, and as a bee plant. The genus *Melilotus* comprises about 20 species, native to southeastern Europe and Asia Minor. They are annual or biennial erect herbs with three-parted leaves of usually small narrow leaflets and small yellow or white flowers borne in slender axillary clusters. Most of the species contain coumarin, resulting in a sweet odour and bitter taste.

Biennial white sweet clover, or Bokhara clover (*M. alba*); biennial yellow sweet clover (*M. officinalis*); and the bitter clover (*M. indica*), a winter annual adapted only to the southern and southwestern U.S., are of agricultural importance in the U.S. and Canada. The first two species have become widely naturalized throughout the U.S. and Canada, while bitter clover is widely scattered in the western U.S. *M. suaveolens*, a yellow-flowered species, is grown in a limited way in the southern prairies of Canada, and occasional plants of *M. altissima* have been collected in the eastern states. Several varieties have been developed such as Madrid for the corn belt, Erector for the Great Plains, and Willamette for the northwest.

See also GRASSLAND.

(E. A. H.; N. Tr.)

**SWEET GUM** (*Red Gum*), a North American deciduous tree (*Liquidambar styraciflua*) of the witch-hazel family (*Hamamelidaceae*), found usually in wet woods and bottomlands from Connecticut to southern Illinois and Oklahoma, south to Florida and eastern Texas. It recurs in northeastern Mexico and from central Mexico to Nicaragua. Sweet gum may grow up to 150 ft. tall and 5 ft. in diameter, but commonly is smaller. Its star-shaped leaves, which become brilliantly coloured in fall, are three- to seven-lobed and up to 7 in. across. Its inconspicuous unisexual flowers are without petals and are grouped into rounded heads: male heads are borne close to the twigs and in clusters; the female heads are solitary on long stalks. The fruit is spiny and consists of many capsules, each of which contains many sawdust-like abortive seeds but only one or two sound seeds,  $\frac{1}{4}$  inch long, brown, and spread by wind.

From the wounded bark of sweet gum exudes a resin known as American storax, used in perfumes, soaps, and medicines. The wood, an important American hardwood, is used for boxes, furniture, millwork, veneer, and barrels. Sweet gum, a desirable ornamental tree, is most safely moved in spring and requires close pruning when transplanted. When planted north of its natural range, it should be placed in a well-drained, sheltered location.

(J. W. Tr.)

**SWEET PEA** (*Lathyrus odoratus*), a hardy annual climbing herb of the pea family (*Leguminosae*) commonly grown outdoors in the cool temperate regions of the world, especially North America and Europe. The sweet pea is a native of Italy, and hundreds of varieties have been developed under domestication. It is one of the most widely used commercial cut flowers because of its excellent durability and the ease with which the plants can be grown in greenhouses.

The fragrant flowers have an unusual colour range: from pure white through cream and various intermediate shades to deep orange; from pink to deep scarlet; and from blue shades to dark purple. In the home garden, sweet pea is often used as a climber in dense rows up to six feet tall or, especially in the dwarfed non-climbing forms (var. *nanellus*), as a colourful compact border. The plants are frost-resistant. In mild climates, seeds may be planted in the late fall about one-half inch deep and two inches apart in rich garden soil for growth during the cool winter and for very early spring bloom. In less mild climates, seeds should be similarly planted in early spring after severe frosts are over and the soil can be properly worked.

These sun-loving plants are usually mulched to conserve soil moisture during their growth.

(R. C. R.)

**SWEET POTATO**, a food plant of the morning-glory family (*Convolvulaceae*; *q.v.*), native to tropical America and widely cultivated in tropical and the warmer temperate climates. It is *Ipomoea batatas*, a tender perennial grown as an annual in regions where frost occurs. The stems are usually long and trailing, and bear entire to palmately lobed leaves of quite variable shape. The

flowers, borne in clusters in the axils of the leaves, are funnel-shaped, tinged with rose-violet or pink, and are similar in size and shape to those of the common bindweed. The edible part is the much enlarged tuberous root, varying in shape from fusiform to oblong or pointed oval. Root colours range from white through cream to orange, and occasionally purple inside, and from light buff to brown or rose, copper, and purplish red outside. The solids of the root consist largely of starch. The orange-fleshed varieties are high in carotene.

The sweet potato rarely produces flowers under common cultural conditions in latitudes higher than about 35°, and produces no seed above latitudes about 30° except under special cultural treatment. The seeds usually produce plants that are unlike the parent plant, therefore the sweet potato is propagated vegetatively by sprouts arising from the roots, or by cuttings of the vines. Seeds, however, are produced commonly in the field in the tropics. They have a very hard seed coat that may retard germination as much as a year, unless the seed coat is nicked or abraded, after which the seeds germinate promptly.

The sweet potato is now widely grown chiefly in the southern United States, in tropical America, the warmer islands of the Pacific, Japan, and the U.S.S.R. It is best adapted to light, friable soils such as sandy loams, since excessive vine growth and small yields or irregularly shaped roots are produced on very rich, heavy soils. At least four to five months of warm weather are required for large yields. In Japan the crop long has been grown for drying and for manufacture of starch and alcohol.

In the United States the sweet potato is propagated usually by bedding the roots close together in sand or light soil in a hotbed heated by manure, by flues or electricity, about four to five weeks before the frost-free date. The sprouts that emerge are pulled from the roots and transplanted to the field about 1 to 1½ ft. apart on ridges 8 to 12 in. high, 3 ft. apart, after the weather and soil have become warm. The roots are harvested mostly about the time of the first frost in autumn, since cold soils cause them to deteriorate. The crop responds well to heavy applications of chemical fertilizers low to medium in nitrogen and high in phosphorus and potash. Heavy applications of animal manures or green manures often result in elongated, irregular roots and root surface injury by scurf, a fungus disease. Roots to be stored should be placed in the storage house immediately upon harvesting, at a temperature of 85° F. and a relative humidity of 85% to 90% for a week to ten days. Then the temperature is lowered to 50°–55° where it is kept as long as the roots are in storage. The "curing" period at high temperature and humidity is essential to hasten the healing of wounds caused in harvesting, thus reducing danger of loss from decay.

The eating quality—and also the market quality and storage life—are greatly improved by curing. If diseases are controlled, roots that are properly cured and stored remain in good edible condition six to seven months.

The sweet potato is very susceptible to several diseases, control of which requires great care in field and storehouse sanitation and management, seed-stock treatment with disinfectants, and crop rotation.

(V. R. B.)

**SWEETSOP** (*Sugar Apple*), a small tree or shrub of the custard apple family (*Annonaceae*), known botanically as *Annona squamosa*. It has thin oblong-ovate leaves, solitary greenish flowers, and a yellowish-green fruit resembling a shortened pine cone. The tuberculate fruit, the fusion of many ripened ovaries and the receptacle, is 3–4 in. in diameter and contains a sweet creamy-yellow custardlike pulp. Native to the West Indies and tropical America, it has been widely introduced into the eastern hemisphere and is much prized as a fruit. See *ANNONACEAE*.

**SWEET WILLIAM** (*Dianthus barbatus*), an old-fashioned garden favourite of the pink family (*Caryophyllaceae*) and one of the most widely cultivated of the many species of *Dianthus* grown in gardens. A relative of the carnation (*q.v.*), it was first introduced into cultivation about 1575 and has since been grown throughout the temperate world. The original European plant and some modern forms are still grown as perennials, but nearly all the finest modern varieties are best treated as biennials. Some

strains bloom from seed in a single season and are grown as annuals.

Sweet William, 12–20 in. high, has flat opposite leaves lanceolate to ovate-lanceolate in shape, and a stem slightly swollen at the joints. The flowers, borne in a profuse flattish cluster (corymb), have toothed petals that are red, white-dotted, or white-striped toward the slightly bearded base. The plant is variable as to colouring, especially in some modern varieties.

Among the many horticultural varieties are excellent scarlet and pink strains that come true from seed and double-flowered strains that usually do not seed true. Another sort, known as auricula-eyed, has white- or pale-centred flowers with a rim of contrasting colour on each petal.

Seeds of the biennial sort are best sown in June, then potted for carrying over the winter in a cold frame. Many biennials and all the perennials often persist from self-sown seed. (N. Tr.)

**SWELLENDAM**, a town of Cape of Good Hope Province, Republic of South Africa, in the valley of the Breede River, is 140 mi. (225 km.) E of Cape Town by road. Pop. (1960) 4,941, including 2,530 whites, 2,242 Cape Coloureds, and 169 Bantu. The town lies among the foothills of the coastal range, and a mountain stream runs down its length. It still has some buildings dating from the early days of South African history, the most notable being the Drostdy (1746), once the residence of the local governing official or *landdrost* and now a historical museum. Swellendam is the centre of a district that produces chiefly wool and wheat, but also apples, peaches, oranges, youngberries, and other fruit. One of the oldest roads into the interior passes through the town. Founded in 1745, Swellendam is one of the older Dutch settlements at the Cape, and was named after the Cape governor Hendrik Swellengrebel and his wife, whose maiden name was Ten Damme. In 1795 the burghers of Swellendam rose in revolt against the Dutch East India Company, expelled the *landdrost*, and set up the first of several local Boer republics in South Africa. (L. L. To.)

**SWETE, HENRY BARCLAY** (1835–1917), English biblical and patristic scholar, whose works on biblical texts are of great importance, was born at Bristol on March 14, 1835, and educated at King's College, London, and Caius College, Cambridge. He was ordained in 1858, and became dean of Caius College in 1865. In 1877 he accepted the college living of Ashdon, Essex, and in 1882 was made professor of pastoral theology at King's College, London. In 1890 he succeeded B. F. Westcott as regius professor of divinity at Cambridge, retiring in 1915. He died at Hitchin on May 10, 1917.

In 1887 Swete published the first volume of his edition of the Greek text of the Old Testament, completing the series in 1894; in 1898 the Greek text of the Gospel of St. Mark with notes and introduction; and in 1906 that of the Apocalypse of St. John. He was the editor of *Cambridge Theological Essays* (1905), *Cambridge Biblical Essays* (1909) and *Essays on the Early Church and Ministry* (posthumous, 1918). His historical and critical works include *The Apostles' Creed in Relation to Primitive Christianity* (1894); *Church Services and Service Books Before the Reformation* (1896); *Patristic Study* (1902); *The Appearances of our Lord After the Passion* (1907); and *The Last Discourse and Prayer of Our Lord* (1913).

**SWEYN I** (d. 1014), king of Denmark from c. 987 to 1014, son of Harald Bluetooth, the christianizer of Denmark. About 987 he rebelled against his father, who fled and died among the Slavs. This unhappy relationship of father and son formed the basis for statements found in the sagas that Sweyn was illegitimate. The history of the early part of his reign is obscure. The 11th-century historian Adam of Bremen alleges that a temporary con-

ROCHE  
SWEET WILLIAM (DIANTHUS BARBATUS)

quest of Denmark by the Swedes took place at this time but there is no foundation for the story. A widely diffused tradition suggests that Sweyn was at some time captured by certain enemies (Slavs, Norwegians, or Swedes) and held for ransom. By 994, however, Sweyn felt strong enough to attempt foreign conquest, and, first ravaging the Isle of Man, he attacked England in alliance with Olaf Trygvesson, an exiled prince of the Norwegian house. The allies besieged London, which was fiercely defended, and harried widely both along the coast and inland. They made peace before the end of the year for a payment of 16,000 pounds. After being baptized, Olaf returned to Norway, where he established himself as king in 995. Sweyn no doubt returned to Denmark. The following five years were marked by his increasing hostility toward Olaf, whom Sweyn, in alliance with Olaf Skötkonung, king of Sweden, and the exiled Norwegian Eric, earl of Hlathir, defeated at Swold in 1000. Olaf was never seen again after the battle, and a Danish rule of Norway through Eric and his brother Sweyn began. King Sweyn turned his attention to England again and led an expedition there in 1003. It ravaged widely, but though helped by treachery among the English, Sweyn suffered one severe defeat in East Anglia in 1004, and returned to Denmark in 1005, perhaps because there was a famine in England that made it impossible for him to feed his men. It is commonly believed that this expedition was a retaliation for the massacre of St. Brice's Day, Nov. 13, 1002, in which Gunhild, a sister of Sweyn, may have perished. Sweyn seems not to have personally accompanied the Danish invaders of 1006, and he certainly was not with the army of Thorkel, which was active in England from 1009 to 1012. One source suggests that Sweyn was disquieted by Thorkel's successes; in any event, he reappeared in England in 1013 and met with rapid success in a masterly campaign. By the end of the year he was master of the country and Aethelred II (*q.v.*) was in exile. He died practically in the moment of victory at Gainsborough on Feb. 3, 1014. He was buried at York, but some years later his bones were removed to Denmark and reinterred at Roskilde.

Little is known of Sweyn's policy apart from his opposition to the formation of a strong independent Norway, and his determination to conquer England. He seems at some time to have made an expedition into Schleswig, for what are apparently grave-stones of two of his soldiers have been found at Hedeby (probably the modern Oldenburg). Sweyn was a Christian and personally appointed Gotebald as bishop of Skaane about 1000. His wife was a Slav princess, sister of king Boleslaw I of Poland, and widow of Eric the Victorious of Sweden. Her name is not known, but late Norse sources call her Gunhild.

See F. M. Stenton, *Anglo-Saxon England*, 2nd ed. (1947); *Encomium Emmae reginae*, ed. by A. Campbell (1949). (AL. C.)

**SWEYN II** (SWEYN ESTRITHSON) (c. 1020–1074), king of Denmark from 1043 to 1074, was the son of Estrith, a sister of King Canute, and of Ulf, a Danish earl. His father fell into disfavour and was murdered by Canute's order about 1027, whereupon Estrith married Robert of Normandy and Sweyn fled to Sweden. After the death of Canute (1035), when Hardicanute was ruling in Denmark and Magnus in Norway, the young kings agreed that whichever lived the longer should succeed to the dominions of the other. Under this agreement Magnus became king of Denmark in 1042. Sweyn made approaches to him soon afterward and was made an earl and viceroy of Denmark. He used his position to acquire popularity and in 1043, while Magnus was involved with the Wends, he was received as king of Denmark. This embroiled Norway and Denmark in a protracted war during the reigns of Magnus (d. 1047) and Harald Hardraade. Sweyn was not a successful commander, and he suffered many defeats, despite support from the Swedes and from disgruntled Norwegians. Yet ultimately Harald, embarrassed by the power of Haakon Ívarsson, a descendant of the earls of Hlathir, acknowledged Sweyn as king of Denmark about 1064.

After Harald's death (1066), Sweyn was in a secure position. He intervened strongly in English affairs in 1069, sending troops and ships to support the rebels against William I, and in 1070 he himself joined the Danish fleet in the Humber. However, he withdrew under an agreement with William.

Sweyn encouraged the development of the church in Denmark, although he was on one occasion embroiled with the archbishop of Bremen, owing to an allegedly incestuous marriage.

Sweyn was a man of peculiarly retentive memory and personally communicated much detailed information to Adam of Bremen, who incorporated it in a history. Sweyn somewhat softened the inglorious story of his Norwegian war; he also claimed to have fitted out an expedition against England and to have secured acknowledgment by Edward the Confessor as his successor.

Sweyn died on April 28, 1074. He introduced a dynasty (the Valdemars) that ruled for 300 years. See DENMARK: History.

(A. L. C.)

**SWIDNICA** (Ger. SCHWEIDNITZ), a town in southwest Poland (Lower Silesia) in Wrocław *województwo* (province). It lies on the Bystrzyca, a tributary of the Oder, in an agricultural area of the Sudeten foothills, 33 mi. (53 km.) SW of Wrocław. Pop. (1960) 39,000. Two old routes meet there, and Swidnica was a fortress early in the 13th century. In 1291 it was incorporated in the Swidnica-Jawor independent Piast principality, passed to Bohemia in 1392, to the Habsburgs in the 16th century, and to Prussia in 1742. It returned to Poland in 1945.

In the Middle Ages Swidnica was an important commercial centre. Its beer was widely exported. In the 14th century it had hemp weaving, and in the 16th century paper was manufactured there. It is a railway junction on the Wrocław-Walbrzych line, and has metal and electro-technical factories. Other developing industries include chemical, leather, timber, textile, food, and fireproof products.

(T. K. W.)

**SWIFT, GUSTAVUS FRANKLIN** (1839–1903), U.S. pioneer in the meat-packing industry, whose promotion of the refrigerator car for railways was a significant step in the industry's development, was born June 24, 1839, at Sagamore (West Sandwich), Mass. When he was 14 he left school to take a position at a salary of \$1 a week working for his brother, a butcher. By 1859, at the age of 20, he had gone into business for himself as a buyer and slaughterer of cattle on a small scale. In that year he opened his own butcher shop in Eastham and soon became the manager of a number of small shops, which he opened himself and placed in the charge of other men. In 1872 he became the partner of James A. Hathaway in the firm of Hathaway and Swift. Three years later Swift, who was the cattle buyer for the firm, transferred his headquarters to Chicago, where the centre of the cattle market had shifted. He soon determined that the meat-packing business would be substantially more profitable than the meat-selling business if some method were devised for shipping fresh meat from Chicago to the east, instead of sending live cattle to be slaughtered on arrival, as was the custom. He therefore hired an engineer to design a refrigerator car which would make this possible, and in 1877 he successfully shipped the first refrigerator carload of fresh meat to the east. In 1878 he formed a partnership with his brother and in 1885, with a capitalization of \$300,000, the firm of Swift & Company came into being, with Swift as first president. At his death less than 20 years later, the capitalization had increased to \$25,000,000, more than 80 times the original size. Swift was also a leader in the field of turning previously unused parts of slaughtered animals into valuable by-products. He died March 29, 1903, in Chicago.

See Louis F. Swift and Arthur Van Vliissingen, Jr., *Yankee of the Yards* (1927).

**SWIFT, JONATHAN** (1667–1745), Irish author, and from 1713 until his death, dean of St. Patrick's Cathedral, Dublin, the foremost prose satirist in the English language, and one of the great satiric masters of all time. His effectiveness results from his resourcefulness in devising satiric situations, the ingenuity and assurance of his execution, and an inimitable prose style: clear, direct, all bone-and-sinew. Although his position as a satirist has been acknowledged ever since his own time, in other respects he has always been a controversial figure, evoking widely disparate, and sometimes severe, judgments, of his work, his personality, and the significance of his fundamental satiric statement. Certain facts about him can be clearly stated. He was outstanding as a wit, a social personality, a clergyman, and a public figure. He

THE GRANGER COLLECTION

JONATHAN SWIFT, PORTRAIT BY CHARLES JERVAS, ABOUT 1718

wrote prose satires as widely different in theme and execution as *Gulliver's Travels*, *A Tale of a Tub*, and the *Modest Proposal*; he was a distinguished minor poet in an age of great minor poetry, and he was a master of political journalism.

**Early Years.**—Swift was born in Dublin on Nov. 30, 1667. He was the son of Jonathan Swift the elder (1640–67) and grandson of the Rev. Thomas Smith, who had been vicar of Goodrich, Herefordshire, and was remembered for his unshakable loyalty to the Royalist cause during the Civil War. Swift's father, with three of his brothers, had settled in Ireland after the Restoration, and had become steward of the

King's Inns, Dublin. In 1664 he had married Abigail Erick, who though she may have been born in Ireland, was the daughter of an English clergyman who had been vicar of Thornton, Leicestershire. A daughter, Jane, was born in May 1666. In the spring of 1667, Jonathan the elder died suddenly, leaving his wife, baby daughter, and unborn son to the care of his brothers.

A posthumous child, and dependent on the generosity of his uncles, with no settled home, Swift may perhaps have suffered from a sense of insecurity. His education was not neglected, however. When he was six, he was sent to Kilkenny School—the best in Ireland—and in 1682, he entered Trinity College, Dublin. In a fragment of autobiography, written many years later, and first published as "Family of Swift" in 1755 (ed. by H. Davis, in *Miscellaneous and Autobiographical Pieces* . . . , 1962), he represents himself as having been so discouraged and sunk in his spirits by "the ill-treatment of his nearest relatives" that he neglected his studies, and so was only granted his B.A. degree (in February 1686) *speciali gratia* ("by special grace"). Actually, his career as an undergraduate seems to have been neither distinguished nor disgraceful, and the manner of his degree a device often used when a student's record failed in some minor respect to conform to the regulations, and not the "discreditable mark" against his name that he himself called it.

He continued in residence at Trinity as a candidate for his M.A. until February 1689, when the disorders that spread through Dublin after the Revolution of 1688 caused the college authorities to give permission for students to withdraw to safety. Swift sought security in England, and after visiting his mother (who had returned to Leicestershire at some date unknown), became a member of the household of Sir William Temple (*q.v.*), at Moor Park, Surrey.

**At Moor Park.**—Moor Park was to remain Swift's headquarters until Temple's death in January 1699, and it was there that he may be said to have achieved intellectual maturity. Temple, a man of wide culture, was engaged in writing his memoirs and preparing some of his essays for publication, and he needed someone to act as secretary. Swift's residence at Moor Park was interrupted; and the fact that he twice returned to Ireland (from May 1690 to December 1691 and from May 1694 to May 1696) points to some uneasiness about his prospects. His first return was in an attempt to obtain a post as secretary, and during his second he took orders, being ordained deacon in October 1694 and priest on Jan. 13, 1695, and at the end of the same month being preferred to the vicarage of Kilroot, near Belfast.

Much happened to Swift between 1689 and departure from Moor Park after Temple's death. He read widely in Temple's library. He met Esther Johnson (the future Stella), the step-daughter of Temple's steward. She was a darkhaired child of eight when Swift first went to Moor Park, and his friendship with her began by his taking a share in her education. Probably in 1693 he went to Kensington on a mission for Temple, who had

been asked for advice on a constitutional problem, and had a conference with William III. In 1692 he went to Oxford, where, after incorporation as a member of Hart Hall, he received an M.A. Also, between 1691 and 1694 he wrote a number of poems; of these six odes are extant.

His true genius did not find expression, however, until he turned from verse to prose satire, and wrote, mostly at Moor Park between 1696 and 1699, *A Tale of a Tub*. This, when published anonymously in 1704, was made up of three associated pieces: the *Tale* itself, a satire against "the numerous and gross corruptions in religion and learning"; the mock-heroic *Battle of the Books*; and the *Discourse Concerning the Mechanical Operation of the Spirit*, against the manner of worship and preaching of the Dissenters.

The *Battle* displays Swift's loyalty to Temple, whose *Essay upon the Ancient and Modern Learning* (1690) had been severely criticized by William Wotton, a defender of modern culture, and the distinguished scholar Richard Bentley (*q.v.*; see also *ANCIENS ET DES MODERNES, QUERELLE DES*). Swift allegorizes the attack on Temple, ridicules Wotton and Bentley, and in the famous episode of the bee and the spider with which the battle opens (in which the spider "feeding and engendering on itself . . . producing nothing at all, but Fly-bane and a Cobweb" is identified with the moderns; and the bee, which, by bringing home honey and wax, furnishes "Mankind with . . . Sweetness and Light" is equated with the ancients) expresses his own tenets concerning the right and universal standards in taste and literature. But it is the *Tale of a Tub* itself that is the most impressive of the three compositions, marked as it everywhere is by exuberance of satiric wit and energy, and by an incomparable command of stylistic effects, largely in the nature of parody. Swift saw the realm of culture and literature threatened by zealous pedantry, and religion—which for him meant rational Anglicanism—suffering attack from both Roman Catholicism and Dissent, and he proceeded to trace these dangers to a single source: the irrationalities which disturb what he regarded as man's highest faculties—reason and common sense.

**Vicar of Laracor.**—With Temple's sudden death in January 1699, Swift entered on a period of varied experience and considerable uncertainty. As nothing offered in England, in the summer he returned to Dublin as chaplain and secretary to the earl of Berkeley, then going to Ireland as a lord justice. During the next 12 years he was in England on four occasions, and won recognition in London for his personal charm and his wit as a writer. Otherwise his position remained unchanged. He had resigned his Kilmot vicarage while at Moor Park, but early in 1700 was preferred to several livings in the Irish Church, the principal being the vicarage of Laracor not far from Dublin. Often in Dublin, he was able to keep in touch with public affairs, both Irish and English. His *A Discourse of the Contests and Dissentions . . . between the Nobles and the Commons in Athens and Rome* (1701) is a forcible statement of his own Whig principles and an appeal to both political parties for moderation. *A Project for the Advancement of Religion, and the Reformation of Manners* (1709) is a reforming tract of a traditional kind. Of other writings of this period—publication of which was, however, delayed—the most notable are the *Sentiments of a Church-of-England Man*, and the *Argument against Abolishing Christianity* (both published in 1711, in his *Miscellanies*), the first a straightforward exposition, the second a masterpiece of ironic disputation against the Deists (see also *DEISM*).

In Ireland Swift remained the comparatively insignificant vicar of Laracor. He was, it is true, on friendly terms with Archbishop King of Dublin, and when in England he kept King informed of matters touching on the Irish Church; and during the longest of his sojourns in London, from November 1707 to June 1709, he was empowered by the Irish bishops to seek from the Whig administration an extension to Ireland of Queen Anne's Bounty, which had been recently granted to the Church of England. But in London he was increasingly well known. His religious and political essays, serious and ironic; the publication in 1704—anonymous but generally attributed to him—of *A Tale of a Tub*; certain *jeux d'esprit*, including the Bickerstaff pamphlets of 1708–09,

which put an end to the career as a popular astrologer of John Partridge (whom he wished to discredit because of his attacks on the clergy) by first prophesying his death and then describing it with convincing detail; and a number of amusing pieces in the minor key, such as *A Description of the Morning*, printed by Steele in the *Tatler* in 1709—these brought him to the attention of the general public as well as to the circle of Whig writers presided over by Joseph Addison (*q.v.*). It is apparent, however, that he found much that gave him uneasiness, less in regard to personal affairs (though anything like adequate recognition in Ireland had escaped him) than in connection with the policies of the Whig administration. Swift was a Whig by birth and education, and the political principles that he had been setting forth in his writings were in the 17th-century Whig tradition. On the other hand, he was passionately loyal to the Established Church, and he came to view with apprehension the growing determination of the Whig administration to strengthen Dissent in Ireland at its expense. Increasingly he was aware of a conflict of loyalties.

Another and momentous period began for him when, on Sept. 7, 1710, he arrived in London. Events of great national importance were under way. A Tory ministry, headed by Robert Harley (later earl of Oxford) and Henry St. John (later Viscount Bolingbroke), was replacing the Whigs; the new administration was bent upon bringing hostilities with France to a conclusion. Also, a more protective attitude toward the Church of England was in prospect. Swift's reactions to this rapidly changing world are vividly recorded at the beginning of his famous *Journal to Stella*, the series of letters extending to 1713 which he addressed to Esther Johnson and her companion, Rebecca Dingley, who were now living in Dublin. The astute Harley, who had befriended Defoe and thereby gained the political services of a valuable writer, made overtures to Swift and, by assuring him that Queen Anne's Bounty would be extended to Ireland, won him over to the Tories. Swift had resolved his dilemma. But though he had placed Church above party, he did not renounce his deeply fixed and essentially Whiggish convictions regarding the nature of government. The old Tory theory of the divine right of kings had no claim upon him. The ultimate power, he insisted, derived from the people as a whole; in the English constitution it had come to be exercised jointly by king, lords, and commons, between whom it was of first importance that a balance be maintained, as a guarantee against all forms of tyranny. Swift sincerely believed that the new ministry reflected in its policies the desires of the whole nation, and was in this sense genuinely moderate. Of its communications with the Stuart Pretender he never knew.

Deceived though he was about the realities of Oxford-Bolingbroke politics, Swift made an important contribution to 18th-century Toryism by exposing it to his doctrine of rational freedom arising out of the whole of society. Quickly he became the ministry's chief political writer. By the end of October he had taken over the Tory journal, the *Examiner*, which he continued to write until June 14, 1711, when he turned to the preparation of a pamphlet in support of the Tory drive for peace. This, called *The Conduct of the Allies*, appeared on Nov. 27, 1711, some weeks before the motion in favour of peace was finally carried in Parliament. Both before this and in the months immediately afterward Swift was also turning out a stream of verse and prose, all politically inspired, whether serious, humorous, or vituperative. His services were not underrated by his friends in the ministry, and it was taken for granted that he would be rewarded by church preferment. But his reward was slow to come, and when it did—in April 1713—it proved to be the deanery of St. Patrick's Cathedral, Dublin, not the English bishopric he had hoped for. He left for Ireland in June 1713 but, early in September, was summoned back to London to heal, if possible, the rift between Oxford and Bolingbroke (see further OXFORD, ROBERT HARLEY, 1st Earl; BOLINGBROKE, HENRY ST. JOHN, 1st Viscount). His efforts were unsuccessful, and in the following spring he fled from the warring ministers, taking refuge in a friend's country parsonage in Berkshire, where the news of Queen Anne's death on Aug. 1, 1714, reached him. With the advent of George I the Tories were a ruined party, and Swift's career in England was at an end.

**Dean of St. Patrick's.**—He was to pass almost all the rest of his life in Ireland. On return to Dublin in the summer of 1714 he found himself the object of scorn and abuse on the part of the Anglo-Irish Whigs, and, bitter over the turn of events and emotionally exhausted, he retired to the seclusion of the deanery. He was, he felt, in a better position than anyone else to record the facts concerning the Oxford-Bolingbroke administration and the negotiations which had culminated, in 1713, in the Peace of Utrecht, and he had already finished several historical pieces, such as the *History of the Four Last Years of the Queen*, written in 1712–13, though not published until 1758. To supplement this he wrote an account of the circumstances attending the Tories' advent to power in 1710, and an *Enquiry into the Queen's Last Ministry*. Both remained unpublished until after his death.

Gradually he regained his full energy. He turned again to verse, which he continued to write throughout the 1720s and the early 1730s, to which period belong such impressive poems as *Death and Daphne*, *Verses on the Death of Dr. Swift* (in which he gives a striking self-portrait), *The Day of Judgment*, *An Epistle To a Lady*, and *On Poetry—A Rhapsody*. By 1720 he was also showing a renewed interest in public affairs. In numerous Irish pamphlets he dealt with many aspects of Irish life. His tone and manner varied greatly, from direct presentation of economic and social facts to exhortation, humour, and irony. He was moved by his perception of the realities of the Irish situation, and by his desire to strike at Sir Robert Walpole and his Whig administration. Ireland's backward state he blamed chiefly on the blindness of the English government, but insistently he called attention to the things the Irish could themselves be doing to better their lot. Of the Irish writings the *Drapier's Letters* (1724–25) and the *Modest Proposal for preventing the children of poor people from being a burthen to their Parents or Country, and for making them beneficial to the Publick* (1729) are the best known, the first being a series purportedly written by M. B., a Dublin linen-draper, attacking the English government for its scheme to supply Ireland with copper halfpence and farthings, the latter a grimly ironic letter of advice in which a public-spirited citizen suggests that conditions could be alleviated were children to be used for food.

Certain events in Swift's private life must also be mentioned. Stella, who died on Jan. 26, 1728, had continued to live with Rebecca Dingley since moving to Ireland in 1700 or 1701. It has sometimes been asserted that Stella and Swift were secretly married in 1716, but that they did not live together: there is no evidence to support this story, however. It was friendship that Swift always expressed in speaking of Stella, not romantic love. The question may be asked, was this friendship strained as a result of the appearance in his life of "Vanessa" (Esther Vanhomrigh)? He had met Vanessa during his London visit of 1707–09, and in 1714 she had, despite all his admonitions, insisted on following him to Ireland. Her letters to Swift reveal her passion for him, though at the time of her death (June 2, 1723), she had apparently turned against him because he insisted on maintaining a distant attitude to her. We are still much in the dark concerning the precise relationships between these three people, and melodramatic theories that have been suggested rest upon no solid ground.

**Gulliver's Travels.**—When Stella died Swift had already enjoyed his greatest triumph as a satiric writer. It is uncertain when he began *Gulliver's Travels*, as the book published as *Travels into Several Remote Nations of the World . . . by Lemuel Gulliver* came to be called. In origin it may perhaps date from the meetings of the Scriblerus Club, a group of Tory writers to which Pope, John Gay, Dr. John Arbuthnot, and Swift all belonged (see LITERATURE, SOCIETIES OF). It is known from Swift's correspondence that he was writing in earnest by 1721 and had finished the whole by August 1725. Since 1714 he had not been to England, but in 1726 he returned, carrying with him in manuscript the work designed, as he said in a letter to Pope (Sept. 29, 1725), to "vex the world rather than divert it." He visited Pope at Twickenham, where he was joined by other Scriblerians, and where he completed arrangements for its publication. *Gulliver's Travels* appeared on Oct. 28, after Swift had left for Dublin. Its success was immediate. Then, as ever since, it succeeded in "vexing" (as

well as diverting) all classes of readers. To what extent is it a political allegory, hinting at the story of Oxford and Bolingbroke, their fall, and Walpole's policies? Is it essentially comic, or intended as misanthropic depreciation of mankind? How seriously are we meant to take Gulliver's utopian sketches? Its matter-of-fact style and its air of sober reality confer on it an ironic depth which defeats over-simple explanations.

Swift visited London once more, in the summer of 1727, to arrange for publication of *Miscellanies in Prose and Verse*, compiled with Pope, of which four volumes were eventually published (1727–32). He also seems to have hoped that an attempt might be made to break the Whig administration. But the death of George I in June 1727 brought the Tories no advantage, and Swift returned to Dublin for the last time in October.

**Later Years.**—The closing years of Swift's life have been the subject of some misrepresentation, and stories have been told of his ungovernable tempers and lack of self-control; it has been suggested that he was insane. From youth he had suffered from what is now known to have been Ménière's disease, an affliction of the semicircular canals of the ears causing periods of dizziness and nausea. But this in no way affected his mental powers, and he remained active throughout most of the 1730s, Dublin's foremost citizen and Ireland's great patriot dean. In the autumn of 1739, as he entered upon his 17th year of office as dean, a celebration was held in his honour. He had already begun to fail physically, and later suffered a paralytic stroke, with subsequent aphasia. In 1742 he was declared incapable of caring for himself, and guardians were appointed. He died on Oct. 19, 1745. He was buried in St. Patrick's Cathedral, next to Stella and beneath the Latin epitaph he had himself composed, which may be translated: "The body of Jonathan Swift, Doctor of Divinity, dean of this cathedral church, is buried here, where fierce indignation can no more lacerate his heart. Go, traveler, and imitate, if you can, one who strove with all his strength to champion liberty."

**Conclusion.**—Intellectually, Swift may be said to have his roots in the rationalism characteristic of later 17th-century England. It was this rationalism, with its strong moral bent, its emphasis on common sense, and its hatred of emotionalism, that gave him the standards by which he appraised human conduct and the norms which he defended in satiric terms. His principles—the positive core of all his work—are scarcely original; his originality is rather a matter of his satiric imagination and art. His tone varies from the humorous to the savage, but each of his satiric compositions is marked by concentrated power and directness of impact. His command of prose style—or rather, of a great variety of prose styles—is unfailing, as is his power of inventing episodes and all their accompanying details. His descriptive passages reflect the minds that are describing more than the things described. Rarely does Swift speak in his own person; almost always he works by ironic indirection through some imagined character like Lemuel Gulliver or the public-spirited citizen of the *Modest Proposal*. It is in his irony that craftsmanship and vision fuse. Swift's irony is operating everywhere: pulling in different directions, it creates the tensions characteristic of his writings. It reflects his vision of man's ambiguous position between bestiality and reasonableness.

**SWIFT**, a bird of remarkable flight speed and maneuverability, any of the 76 species composing the family Apodidae (formerly Micropodidae). Although resembling swallows superficially, swifts are a nonpasserine group closely allied to hummingbirds. They are virtually cosmopolitan but are not found at higher latitudes and on some oceanic islands. Many species are migratory. Of small to medium size (3½-9 in.), they have compact bodies, small bills, large gapes, extremely short legs, and very small feet with a reversible first toe. The wings are long and pointed and the tail either short and truncate (sometimes spine-tipped) or very long and forked. The plumage is usually drab, blackish or bluish to gray-brown.

Swifts are the most aerial of birds, even mating and bathing on the wing. They subsist on insects captured in flight and rest only by clinging to vertical surfaces. The nests, of a salivary secretion or of plant fragments, etc., cemented together with the secretion, vary from simple wall-hugging brackets to long elaborate tubes. In parts of the Orient the hardened saliva nests of certain cave-dwelling swifts (*Collocalia*) are considered a delicacy when prepared as a soup. Best known of American species is the chimney swift (*Chaetura pelagica*), a blackish, swallowlike bird that breeds throughout the eastern U.S. and winters in the upper Amazon drainage; during migration, these birds congregate in chimneys and hollow trees at dusk.

The closely related crested or tree swifts (family Hemiprocnidae) have crests, soft plumage, and strong legs adapted for perching. The three species are found in southeastern Asia and nearby islands. (E. R. Be.)

**SWIMMING**, the action of self-support and self-propulsion on or in the water; though used by analogy of inanimate objects, the term is generally connected with animal progression and especially with the art of self-propulsion in the water as practised by man. Swimming and diving are among the most useful of man's physical accomplishments and most popular recreational and sports activities.

Swimming was rated highly in the days of Greece and Rome. It was practised widely and stressed in the training of warriors. But it fell into almost complete disuse throughout Europe in the Middle Ages, when the belief became general that outdoor bathing helped to spread the epidemics that so often swept across the continent.

It was not until the second half of the 19th century that this medieval prejudice was overcome sufficiently for aquatic activities to be resumed. Competition was resumed, first in Great Britain, then elsewhere as a national and international competitive sport. Swimming was one of the sports included in the revived Olympic Games at Athens in 1896, diving events were added in 1904, and women's swimming and diving in 1912.

## TEACHING SWIMMING

There have been many cases in which beginners have demonstrated some ability in swimming upon their first immersion in the water, but generally speaking it is a skill that must be acquired. With the increasing acceptance of swimming as a recreation, there came increasing appreciation of its value in protecting life as well as in physical education, for it had gained recognition as one of the most beneficial of all forms of exercise. Many physical educators hold that there is no comparable physical activity that can contribute as much as swimming to a person's physical well-being.

Teaching of swimming was taken up by the schools; sectional and national learn-to-swim campaigns were fostered in most countries. During World War II nearly all belligerent nations included swimming as a part of the training of servicemen, and after the war the gains in swimming instruction and promotion that had been made were consolidated and furthered by national organizations such as the U.S. Conference for National Cooperation in Aquatics. This organization, operating informally and meeting annually, sought to further the cause of swimming specifically because of its safety value but also because of its value as an all-around exercise.

**Methods.**—Many methods of swimming instruction were tested as changes in stroke took place, but in the long run the great majority of teachers enrolled in one of two predominant schools, the European, whose protagonists believe the breaststroke should be taught first, and the U.S., whose followers assert that the crawl is mastered far more readily than any other stroke. Both schools favour preliminary drills on land or in shallow water, so that beginners may gain some knowledge of the required movements before attempting to swim.

The greatest handicaps in learning are failure to relax and haste in performing the action. Fear of the water, or the mere nervousness experienced by most nonswimmers, generally causes muscle tension and engenders the feeling that it is necessary to thrash wildly with arms and legs in order to keep afloat. Every effort must be made to overcome these natural tendencies, for rapid progress is dependent upon complete relaxation and unhurried movements. Instructors usually help pupils to become accustomed to immersion by having them play in shallow water, ducking the head and trying to pick up objects from the bottom, before starting schooling.

During World Wars I and II, when great numbers of men in their late 20s and early 30s had to be taught and speed in training was essential, a method of starting the pupil on his back was developed. In this position floating was facilitated, developing confidence in the water; normal breathing was utilized in contrast with the breathing difficulty in face-down strokes, and a very simple propulsive action was taught—a frog kick with a synchronous short arm stroke, the arms being underwater to prevent splash.

**Floating.**—One of the most useful accomplishments of a swimmer is floating. It is a matter of buoyancy, which varies with individuals. Buoyancy cannot be taught, but body balance in the water can be acquired through knowledge. In learning to float, the beginner experiences difficulty in keeping the legs in the horizontal plane, and this can be remedied by the counterbalance of extending the arms beyond the head, whether in face down or back floating position.

Floating motionless can be performed with proper breath control and body balance. Bending the knees to shorten the axis often improves balance in the water. Supine or back floating with a minimum of motion of the arms and legs is a valuable safety skill for the swimmer as well as for the novice.

Movement of the legs in an alternating walking motion and downward pressure of the hands and forearms is the only motion required to keep the body comfortably afloat in the back floating position.

## SWIMMING STROKES

Types of swimming strokes commonly used are the breast, side, crawl, back, and butterfly. Each of these has been popular at different periods. The Australian crawl is probably the best known stroke. In the early stages of competition, the standard racing

## SOME SWIMMING STROKES

(Above) Side stroke and scissors kick; (left) orthodox breaststroke and frog kick; (below) butterfly stroke

RUSS KINNE

style was the side stroke, in which both arms remain submerged throughout, while the legs execute a wide scissor kick, opening and closing in movements resembling those of walking. The first advance over this was made when swimmers conceived the idea of minimizing resistance by thrusting the upper arm forward above the surface, instead of underwater. The new stroke was called the single overarm. The double overarm followed, with both arms recovering above the surface. This stroke was made prominent in 1893 by an Englishman, J. Trudgen, who told of picking it up in South America. It took his name, misspelled Trudgeon in some countries, and served later to introduce the basic arm action of the crawl, the most efficient mode of swimming developed so far.

The changes in leg drive were marked by a consistent trend toward narrower and faster movements. Following the advent of the trudgen, the wide scissor kick of the side stroke, originally performed with legs bent excessively, was reduced in scope and executed with the legs a good deal straighter. Then, with the introduction of the crawl, the legs began to whip up and down alternately in a gradually quickening and diminishing thrash, speeding up by degrees from two to ten proportionately smaller scissors to each cycle of the two arms.

**Breaststroke.**—Two styles of breaststroke have been evolved, the ancient and orthodox variety, believed to be the oldest of all strokes, and the butterfly, a racing adaptation brought out in 1935 by Henry Myers of the United States. The orthodox breaststroke, used by the European school for teaching beginners, is a stroke of great practical value. It affords the means to assist a tired swimmer or support a drowning person with comparatively little effort; it enables the swimmer to advance safely, head up, through waters littered with flotsam or wreckage.

The breaststroke and the butterfly are distinguished by differences in the action of the arms. In both the arms start their drive from full extension in front, hands close together on the surface, palms down. But in the orthodox breaststroke the arms propel by pressing down and outward at a slant that places them at an angle of about 80° on reaching the shoulder line, when the

elbows are brought to the sides, the hands to the chest, again palms down, and the arms shoot forward underwater to their original position. In the butterfly the arms pull under the body all the way to the thighs, then emerge and fling forward above surface in circular motion.

The leg action for the breaststroke, known as the frog kick, is performed by drawing up the legs in a manner somewhat like that of squatting, knees apart, feet close and pointed; then the feet are turned outward, and, with a continuous sweep, the legs are kicked vigorously back and out, and snapped sharply together as the arms shoot forward in recovery. After the kick the body is allowed to glide motionless for a brief spell, forming a straight line from hands to pointed toes. The orthodox stroke may be used comfortably head up, but greater speed is attained in both styles by raising the head to inhale during the drive of the arms and dipping the face to exhale underwater during their recovery. The butterfly is the faster by a wide margin.

**Butterfly.**—Regulations governing competition in the butterfly

were revised in 1952 to permit a synchronous up-and-down action of the legs characterized by the term "fishtail kick," or "dolphin." This new kick resulted in the separation of the breast and butterfly strokes competitively. In the breaststroke it was ruled that the arms and legs must remain *under* the surface. In the butterfly stroke the leg kick could either be executed in the traditional breaststroke manner or be a simultaneous up and down movement of the legs and feet in the vertical plane. The arms must be brought forward *over* the water and brought backwards under the water simultaneously and symmetrically.

Since the separation of the breast and butterfly strokes there has been a constant study of the breaststroke technique in an endeavour to secure greater speed in competitive events. The body position is now flatter on the surface. The glide phase between the propulsive limb movements has been practically eliminated and the leg kick is narrower. Both result in the arms and leg actions being almost continuous.

**Side Stroke.**—The side stroke is valued chiefly for lifesaving purposes, as it is used in the most efficient carries devised for the rescue of the drowning. But it is liked for open-water pleasure swimming also, because it is faster than the breaststroke and the face remains constantly above water. The body stays steadily on its side, as the name implies, and the arms propel alternately. The under arm starts from comfortable extension overhead and pulls below the body to the waist, then bends upward and pushes forward; the upper arm drives a little outside the body line, sweeping to the thigh, and recovers close to the surface. The legs open slowly for the scissor kick, the under leg moving backward, the upper leg forward, both knees bent a little, feet pointed, then whip smartly together, the closing movement timed with the finish of the upper arm drive. This stroke is also excellent for survival swimming or for emergency situations where it is imperative that the arms in all actions be kept underwater.

**Crawl Stroke.**—The crawl is the fastest of all known strokes, yet it requires little effort, as attested by the fact that many of the greatest feats of endurance achieved by men and women stand to its credit, including crossing the English Channel and

swimming the length of the Panama Canal. Its remarkable speed has made the crawl not only supreme in the competitive field (it is the universal choice in free-style events) but also extremely valuable in saving drowning persons, in getting away from a sinking ship and in battling strong tides or currents in the effort to reach safety.

**History.**—There is evidence that the crawl was well known in some of the South Sea islands long before Richard Cavill of Australia introduced it into England about 1900 and broadcast its merits by breaking the world record for 100 yd. with it. It was discovered that the stroke had been popular in the Solomons as far back as the oldest islanders could remember, and long before it was introduced in Australia, sportsmen in Honolulu frequently arranged swimming races at Waikiki Beach in which young Hawaiian swimmers used a stroke very similar to the one later demonstrated with such success by U.S. Olympic champion Duke Kahanamoku. The name of crawl was coined as the result of a press account of the initial showing of the stroke, in which the writer stated that Cavill appeared literally to crawl over the water. Cavill performed two kicks per full stroke, and his action was adopted universally in Australia, so the leg drive remained unchanged until the stroke made its way to the United States.

The earliest knowledge of the crawl obtained in the U.S. was derived from hazy newspaper accounts and descriptions of Cavill's strokes. In attempting to imitate the action, U.S. swimmers unwittingly developed a faster leg drive, executing four scissoring kicks per stroke instead of the two performed by Cavill. The new leg drive was combined with the double overarm action of the trudgen, and the resulting stroke was called the four-beat crawl, to distinguish it from the two-beat variety.

Meanwhile, experiments had led to the belief that the four-beat leg thrash was most effective when composed of one comparatively wide and three very narrow scissoring motions. This style, termed the four-beat trudgen crawl or the four-beat single rhythm crawl, became the accepted racing stroke. The combination of movements was responsible for so notable an improvement in average performances that technical experts conceived the possibility of obtaining still greater speed from a six-beat drive set to a double rhythm—two major and four minor kicks—which would minimize resistance and afford more even distribution of propelling power. But coaches were unanimous in declaring that the swift thrash would prove entirely too laborious for distances longer than 100 yd., and the subject was dropped temporarily.

Late in 1917 two young swimmers of the New York Women's Swimming Association, Charlotte Boyle and Claire Galligan, determined to give the six-beat a trial, and by the summer of 1918 they broke records with it over the longer regulation courses, 880 yd. and one mile. So convincing was this demonstration that it caused a sudden change of mind among the coaches and competitors. The six-beat crawl immediately won favour in the U.S., presently in other countries, and within a few years it had become the recognized stroke the world over, not only for racing but also for all-around purposes. Another Women's Swimming Association member, Ethel McGary, successfully developed in turn the eight- and ten-beat varieties of the crawl, but as the eight- and ten-beat

strokes were found to require exceptionally limber legs, in time the six-beat crawl came to be accepted as the standard action. Nevertheless, a great many women and some men used the eight-beat successfully. It enabled Gertrude Ederle of the U.S. to cross the English Channel in 14 hr. 34 min. and break the men's record for the course, 16 hr. 33 min. No men and very few women have made their mark with the ten-beat crawl.

In spite of the widespread acceptance of the six-beat crawl, in the 1960s tiny (5 ft.-1½-in. 108-lb.) Los Angeles teenager Patty Caretto combined an exceptionally fast stroke with a two-beat kick and in 1965 set world records at 1,650 yd. (18 min. 51.1 sec.) and 1,500 m. (18 min. 23.7 sec.).

The development of speed swimming is still in its infancy, as witnessed by the advances made in skill since the introduction of the crawl stroke. With increased skill in swimming as a result of widespread and ever-expanding instruction and facilities, it is difficult even to guess what the future holds.

**Method.**—The position of the body in swimming the crawl is like that assumed in standing erect on tiptoe. The arms move alternately, so timed that one will start pulling just before the other has completed its drive, thereby making the propulsion continuous. Each arm catches in front of the body in line with the shoulder on the same side, almost fully extended with elbow and shoulder slightly flexed. Such slight flexion affords greater strength and arm position than does full extension. The elbow on catch is slightly higher than the hand, forearm turned slightly inward, wrist straight, hand palm down, fingers and thumb close but not cupped.

The power of the arm stroke can be thought of as pressing downward and backward during the first third of the stroke, pulling during the middle third and pushing through and backward but not upward during the final third of the action, completing an arc of roughly 180°. The direction of pull should be on a line from the shoulder moving slightly under the body and out past the thigh on recovery.

On recovery the elbow is bent and the forearm circles quickly out and around until it points toward the place of entry. Then the elbow is extended for the catch of the arm on a line with the shoulder.

The legs are held fairly straight but fully relaxed. The legs whip up and down alternately in an undulating action so that in both the up kick and down kick there will be a backward push against the water with the lower leg and more so with the foot. The scope of the thrash must vary somewhat according to the individual length of leg, the number of beats used per stroke and the distance to be covered.

Breathing is effected by turning the head to either side during the recovery of the upper arm, for the purpose of a gasping inhalation, and then returning the head squarely face downward, exhaling through the nose or nose and mouth. One breath is taken for every full stroke (right and left arm). The skilled swimmer learns to breathe on either side, but the regular breathing pattern is established on one side or the other.

Crawl balance is attained by working the arms independently of the shoulders so that the body lies perfectly flat even during the

COMPETITIVE SWIMMING STROKES

(Left) Free-style competition in which, although any style may be employed, the crawl is preferred; (right) backstroke

action of inhalation, when the head turns without distorting the trunk position. The shoulders are level at all times; the water line of the head is at the eyebrows when the face is down, and any distortion of the trunk in the shoulder or pelvic girdle should be avoided.

**Backstroke.**—The style of the backstroke in vogue prior to 1912 was aptly described as an inverted breaststroke. But that year Harry Hebner, the U.S. champion, amazed spectators in the Olympic race at Stockholm with his supine crawl, never before seen in Europe, winning in record time. That exhibition soon drove the old stroke (double overarm on the back with a frog kick) into discard, for the back crawl is a good deal faster, requires less effort and is easier to learn. In the back crawl the swimmer's position is such that the body is in a horizontal plane, head lifted slightly upward looking at the feet, with hips slightly lower than the shoulders. The arms work alternately and are intertimed as in the prone crawl or free style. Each arm stretches above the head and enters the water six inches to a foot outside the shoulder line, pulling and driving to the thigh with a circular outward motion at a depth sufficient only to keep the arm underwater in a plane parallel to the surface of the water. The arms in recovery are carried straight or with a partially flexed elbow to the catch, either in line with the shoulder or in a semicircular motion side-ward and upward. The shoulders and trunk are kept flat without any rolling. The legs execute an alternate thrash as in the prone crawl; the knees bend more but are kept underwater at all times. This makes for a much deeper kick (leg and foot) than in the prone crawl. In the back crawl, with the face out of water all the time, the breathing presents no difficulties as it does in the breaststroke, prone crawl, and butterfly.

### COMPETITIVE SWIMMING

Swimming joined the ranks of standardized competitive athletics in 1869, when the Amateur Swimming Association was founded in England. Other countries followed the lead at intervals, the U.S. launching the Amateur Athletic Union in 1878, and before many more years nearly all western nations had formed governing bodies and taken measures to promote the sport. Eventually, national championships for men and women, as well as intersarsity and interscholastic title tests, were instituted everywhere. International competition was inaugurated with the holding of the revived Olympic Games at Athens in 1896. Activities grew apace thereafter, and frequent intercountry encounters were added to the quadrennial Olympiads, making increasingly evident the desirability of unifying rules and regulations.

To this end, the International Amateur Swimming Federation (Fédération Internationale de Natation Amateur; FINA), composed of controlling national organizations, was formed in London in 1908. It undertook to draft a code, supervise and register world's records, and outline programs for Olympic Games. As membership was made conditional to the observance of all FINA rules, universal standards were soon established. The federation chose swimming, diving and water polo as the branches of aquatic sports over which it would assume authority. The three classes of swimming events already popular were retained: free style, permitting the use of any kind of stroke; backstroke, regulated by the one provision that the entire course must be covered in supine position; and breaststroke, confined to this mode of swimming and governed by strict rules concerning the execution of the action. A fourth class—the butterfly stroke—was added to the 1956 Games program. Whereas the 1896 Games at Athens included only four events on the program, swimming has grown to a full-fledged international sport with 12 events for men and 10 events for women included in the 1964 Games in Tokyo.

Synchronized swimming has been added to the list of competitive sports held under the rules of the FINA. This is a planned routine of artistic water skills and strokes which are synchronized into a flowing routine accompanied by music. Many intricate routines are performed which call for balance, rhythm, endurance, watermanship, and coordination. Competitions comprise solo, duet, and team events.

Free-style races have always furnished the bulk of the competi-

tion in the Olympic schedule. In national championships, free-style predominance is even greater. Although long-distance races are an integral part of summer activities, most competition takes place in pools. The building of large numbers of enclosed and heated pools, especially after World War II, speeded the growth of aquatic contests during the winter months.

In the 1896 Olympics, Hungary took top honours with two wins to one each for Greece and Austria. The II Olympiad in 1900 saw Australia, Germany, and Great Britain win two events each and France one. The United States took its first Olympic swimming victories at St. Louis in 1904, winning two of the free-style events, and a relay. Germany won four victories and Hungary two. Great Britain, in 1908, showed its superiority by winning four of the swimming events, but the 1912 Olympics, marked by the initial appearance of women contenders, was practically a standoff with Canada, Germany, and the U.S. winning two events each.

World War I caused the 1916 games to be canceled, but by 1920 the U.S. was ready to profit from earnest study of the crawl. In the 1920 Olympics the U.S. took five of seven swimming events, the other two going to Sweden. At Los Angeles in 1932, while the U.S. women successfully defended their laurels, the men were defeated by the vastly improved Japanese, winners of all but one of the contested swims. Competition was close at Berlin in 1936 in the men's swimming events, which resulted in three victories for Japan, two for the U.S., and one for Hungary. The Netherlands' women's team won four of the five women's races—the 100- and 400-m. free style, the backstroke and the relay—losing only the breaststroke event to Japan. This was the first time that Japan had taken a first place in the Olympic games in women's swimming and the first time since World War I that the U.S. women's team had been unable to win a first place.

In the London Olympic games of 1948 the U.S. men's team won first place in all six events, the first time since the Olympic games revival that any nation had achieved such a sweep. In women's swimming, the team from Denmark, which had been sharing honours with the Dutch team in international swimming circles since 1936, won two first places—the 100-m. free style and the backstroke. The team from the Netherlands won the breaststroke event; and the U.S. team with Ann Curtis won the 400-m. free-style race and the relay.

The U.S. maintained its leading position in men's swimming at the Helsinki Olympic Games, 1952, winning four races—the 100- and 1,500-m. free style, the backstroke and the relay. France, after great advances during several Olympiads, won a magnificent victory in the 400-m. free style, and Australia won the breaststroke. Women's swimming supremacy saw another great shift, from northern Europe, the Netherlands, and Denmark to central Europe. The women's team representing Hungary won four of the five races in a most outstanding and convincing manner—the 100- and 400-m. free style, the breaststroke, and the relay—and the backstroke race was won by South Africa, the first time this team had ever won an Olympic swimming competition.

The 1956 Olympic Games at Melbourne, Austr., served notice that the Australians had arrived as the world power in swimming. Australian competitors took all free-style titles in both men's and women's events in a magnificent display of form and power. New records were established for every event on the Olympic program except for the men's and the women's 200-m. breaststroke events.

Two years later, in Australian state and national competition in the spring of 1958, 31 new world records were reported. Fifteen-year-old Latvian-born John Konrads and his 13-year-old sister Ilsa accounted for 16 of the new marks.

At Rome, for the 1960 Olympics, Australia and the U.S. took four events each in the men's swimming events while in the women's competition five of the seven races went to the U.S. swimmers and one each to Australia and Great Britain.

With increased swimming facilities the world over, and means of communication and transportation making possible more and more international meets in addition to the Olympic Games, excellence in performance follows no one pattern or nation, which is checking of the record clearly indicates (see OLYMPIC GAMES

Never, however, has one country so completely dominated the

Olympic Games swimming events as did the United States in Tokyo in 1964 when it gained 16 gold, 10 silver, and 11 bronze medals. Seventeen-year-old Don Scholander, U.S., secured an unprecedented four gold medals in Olympic swimming. Australian Dawn Fraser became the first swimmer to win an Olympic title on three consecutive occasions when she retained the women's 100-m. free style. The Soviet Union gained its first Olympic victory in the swimming events when Galina Prozumenschikova won the women's 200-m. breaststroke in 2 min. 46.4 sec. Every Olympic record was beaten and 14 world marks fell during the Games.

Various factors contributed to the resurgence of the United States in swimming. One, Age Group Swimming, is the nearest thing to a nationally organized sports program the United States and the West have produced in an Olympic sport. Conceived about 1950, it is a program in which both boys and girls can compete against local, sectional, or national standards in age groups starting at 10 and under, and including 11-12, 13-14, and 15-16. This program has attracted more than a half million youngsters and has been responsible for the development of many fine swimmers.

Following the tremendous competitive successes of the United States in the 1964 Olympic Games, due largely to the national age-group program, most countries adopted this type of competition at a national level. This development led to age group international contests.

New ideas in training have also contributed to general improvement in all phases of swimming. Out-of-water exercising, both in and out of season, includes running as well as body building—a system of free exercise using no equipment. Also included are weight lifting, isometric and isotonic exercises, and the use of an almost unlimited variety of training gadgets invented to improve muscle tone, to increase endurance, and to develop strength.

Along with out-of-water conditioning, Repeat Training and Interval Training have influenced the sport for better performances. Formerly, training was largely a matter of the distance a swimmer could travel in a given training session, without regard to quality and speed. Repeat and Interval Training have largely replaced the swim-for-distance technique. In Repeat Training the emphasis is on intensity rather than quantity: a swimmer swims 50 or more 50-yd. sprints at 80 to 90% capacity, with rest periods between sprints equal to the time it takes to swim each sprint. Distances can be increased up to 400 yd. with proportionally longer rest periods.

In Interval Training, sometimes known as "locomotives," the emphasis is on quantity rather than intensity. It consists of distance swims with two variations in speed, fast and very slow: a swimmer swims one lap fast, one slow, two laps fast, one slow, three laps fast, one slow, two laps fast, one slow, one lap fast, one slow. Another variation is to swim two laps fast, one slow, for distances of 200-800 yd. or over. While the emphasis here is

## DIVING

Some key attitudes shown in mid-dive: (left) inward, pike; (top right) backward, layout; (bottom right) forward, half twist

on quantity, the fast swimming required helps the swimmer to increase his capacity for continuous effort.

## DIVING

Diving for pleasure and exercise can most easily be performed by standing on the edge of a pool or dock, holding the arms overhead and bending forward at the hips until the balance is lost. The entry into the water will be smooth and without ill effect.

Diving, plain and fancy, which is a part of all aquatic contests, developed rapidly through the first half of the 20th century. Many gymnastic and tumbling stunts can be performed before entry is made into the water, and the thrill of this combination is a challenge to young persons to achieve perfection in this stimulating sport.

Diving became a part of the swimming program of the Olympic games as early as 1904. The program at that time was plain high diving and variety high diving, with contestants performing from both the 5-m. and 10-m. firm platforms. The contest was composed of compulsory dives and voluntary dives. Springboard diving, plain and variety, was performed from an elastic board at heights of 1 m. and 3 m. above the water. It was necessary to have judges to mark the dives performed, with attention paid to the take-off, the bearing of body in the air and the entrance into the water.

The Olympic committee composed a table listing the type of dives allowed, their description, and a value for each dive based on the difficulty of performance. These early tables comprised 14

dives from the high firm platform and 20 from the springboard, as compared with the 46 and 47 in the second half of the 20th century.

To indicate the advances made in diving, it can best be described by comparing the dives of yesteryear with today's complex stunts. The report following the IV Olympiad suggested elimination of the double somersault because it was believed that a diver could not control the execution of such numerous spins without chance of injury. Today, divers from most sections of the world are confidently somersaulting  $2\frac{1}{2}$  times backward and  $3\frac{1}{2}$  times forward from both firm and springboard elevations. The combinations of spins and twists are often done, and a forward  $1\frac{1}{2}$  somersault is often combined with a triple twist, performed with a high degree of skill.

Beginning with the Olympic Games of 1920, which excluded German athletes, U.S. divers dominated international competition. This supremacy can be credited to three U.S. coaches: Ernst Brandsten, an outstanding Swedish diver in the 1912 games whose chief contribution was his thoroughness in teaching fundamentals and his success in standardizing equipment; Fred Cady, a sports-minded artist whose sensitiveness to grace and poise had great influence; and Mike Peppe, a Midwest coach who developed more national and international diving champions than any other coach. The combination of ideas and teaching represented by such men as these produced U.S. diving champions in all Olympic events after 1920 except for the men's high dive event in 1920, 1924, and 1956; the women's high dive in 1920, both women's events in 1960, and the women's springboard in 1964.

**The Groups of Competitive Dives.**—Competitive dives are divided into five groups encompassing springboard dives and fixed platform dives, with the addition of arm-stand dives done from fixed platforms. The first includes the forward dives, in which the person dives out away from the platform and rotates  $\frac{1}{2}$  turn to  $3\frac{1}{2}$  turns before entering the water. The second group comprises backward dives, in which the diver stands at the edge of a platform and rotates backward  $\frac{1}{2}$  turn to  $2\frac{1}{2}$  somersaults. The third group, the forward motion and reverse spin dives, is commonly called the reverse group. In this form of diving the diver can rotate in reverse from  $\frac{1}{2}$  turn to  $2\frac{1}{2}$  turns.

The fourth group is that of inward dives. In this category the diver stands on the outer edge of the platform and jumps backward with a forward rotation from  $\frac{1}{2}$  turn to  $2\frac{1}{2}$  somersaults. The fifth and last classification is that of twisting. In this movement the diver rotates the body on the long axis, from  $\frac{1}{2}$  twist to  $3\frac{1}{2}$  twists, while revolving on the short axis from  $\frac{1}{2}$  turn to  $2\frac{1}{2}$  somersaults. With the possibilities of combining all groups with twisting, it can easily be seen why the last grouping offers more dives than any other from which the diver can choose his optional dives.

The majority of dives included in the roster may be executed

in three distinct positions; namely, straight, pike, or tuck. In the first position (straight), the body must be held extended, and no flexion at the hips or knees is allowed. In the second position (pike), there may be a bend at the hips, with no knee flexion. In the third position (tuck), both the knees and hips are flexed and the position of the body resembles a ball. In all positions the feet must be pointed.

**Diving Board.**—The surfaces of diving boards, whether firm or flexible, must be covered with cocoa matting or some other non-skid material the full length of the run. Springboards may be made of wood, aluminum, steel or other resilient material. Standard equipment for springboards is the adjustable fulcrum, which enables the diver to adjust the flexibility of the board to his liking.

### CHANNEL AND OPEN-WATER SWIMMING

Much interest has centred in the many attempts to swim across the English Channel. The first recorded attempt was made on Aug. 24, 1872, by J. B. Johnson, who started from Dover but remained in the water only 65 min. On Aug. 12, 1875, Capt. Matthew Webb made his first attempt. He started from Dover and remained in the water 6 hr. 49 min., until the weather became too rough for him to continue. It is estimated that he was about 13½ mi. across when he had to give up. On Aug. 24 and 25, 1875, Webb swam the channel, diving from the Admiralty Pier, Dover, and touching Calais Sands after swimming for 21 hr. 45 min. The accomplishment created a great sensation in England, and many swimmers have since repeated Webb's performance.

The enjoyment and pleasure derived from bathing and open-water swimming in salt or lake waters make it among the most popular of all sports and recreational activities the world over, but proper caution in water activities should be taken.

Swimming in unsupervised areas should be avoided. A person should never swim outward from shore for any great distance without an accompanying boat. If he is caught in sea grass or weeds, he should not struggle against it but rather gently shake the arms and legs until the grass floats free.

Tides, riptides, and undertow must be noted in offshore swimming, and knowledge of safety skills in such circumstances can save lives. Riptides are riverlike masses of water caused by the contour of the bottom. They are bound on both sides by eddies that swing back toward shore. A swimmer should never attempt to fight a riptide but rather swim diagonally with it and to its edge then swing into the eddy and be carried in toward shore. Undertow or backwash is simply the receding portion of the water that has been carried in by the breakers. Because of its movement outward from the shore, it is very disconcerting. Fortunately the water travels in two directions at two levels. The upper level travels inward and the swimmer should push off the bottom and emerge at the surface and go with the breakers toward shore.

Tides may cause currents running diagonally toward the beach and the best procedure is to swim across or with them until shallow water is reached.

Due to the increased popularity of such activities as sailing, boating, skin and SCUBA (self-contained underwater breathing apparatus) diving, underwater spear fishing, water skiing, and surfboarding, more people are taking to the open water as a form of recreation. A large percentage of drownings could be prevented if each person exercised caution and gained a thorough understanding of his own abilities before engaging in these sports.

For Olympic records in all aquatic events see OLYMPIC GAMES. See also DROWNING AND LIFESAVING; SKIN DIVING; SURF RIDING; WATER POLO; WATER SKIING.

**BIBLIOGRAPHY.**—The literature on the subject of swimming is considerable; a useful work of general reference is Ralph Thomas' (1904), which contains a bibliography from the earliest time. Other works that may be mentioned are: R. J. H. Kiphuth, *Swimming* (1942); Frances A. Greenwood, *Bibliography of Swimming* (1940); T. K. Curreton, *How to Teach Swimming and Diving* (1934); U.S. Naval Institute, *Swimming* (1944); R. J. H. Kiphuth and H. M. Burke, *Basic Swimming* (1950); John A. Torney, Jr., *Swimming* (1950); D. A. Armbruster and others, *Swimming and Diving*, 4th ed. (1963); Max Madders, ed., *Swimming: the Official Coaching Book of the E.S.S.A.* (1951); R. Dawson, *Age Group Swimming* (1961); F. Carlile, *Forbes Carlile on Swimming* (1963); W. J. Juba, ed., *Swimming* (1961); B. Rajki, *Technique*

**SWINBURNE, ALGERNON CHARLES** (1837-1909), English poet and critic, outstanding for the boldness of his prosodic innovations and the brilliance and strangeness of his personality, was born in London on April 5, 1837. His childhood was spent partly on the Isle of Wight, where his father rented a house and part of the shore at Bonchurch, and partly at his grandfather's estate in Northumberland. The cliffs and crags of both places made a deep impression on him, and he early developed an intense love for the sea. Despite his later republican sympathies, Swinburne was proud of his aristocratic origins. His father was an admiral, his mother a daughter of the earl of Ashburnham, and his grandfather—who had been the friend of radicals and revolutionaries in France and had great influence over his grandson—was Sir John Swinburne, 6th Bart. Swinburne also liked to think that he was descended from the French house of de Polignac—a claim quite without foundation.

After being taught by his mother and then by a tutor, he went to Eton (1849-53), and, after private tuition, to Balliol College, Oxford. He left Oxford, without taking a degree, in 1860. While there he met Edward Burne-Jones, William Morris, and D. G. Rossetti and so became connected with the Pre-Raphaelites. After leaving Oxford he often visited Benjamin Jowett, his tutor. He shared a house in Chelsea with Rossetti and George Meredith (q.v.) from 1862 to 1864, when he took lodgings which he occupied intermittently until 1879. An allowance from his father enabled him to follow a literary career. In 1861 he met Richard Monckton Milnes (later Lord Houghton, q.v.), who encouraged his poetry, fostered his reputation, and introduced him to the works of the marquis de Sade. In 1864 he traveled to Italy and met the aged Walter Savage Landor.

Literary success came with the publication in 1865 of *Atalanta in Calydon* (dedicated to Landor). The first series of *Poems and Ballads* followed in 1866. It was vehemently attacked for its "feverish carnality"—even *Punch* referred to the poet as "Mr. Swineborn." It was, however, enthusiastically welcomed by the younger generation, and the influential Ruskin acknowledged the arrival of a genius.

In 1867 Swinburne met Mazzini, and under his influence *Songs Before Sunrise* (1871) was principally concerned with the theme of political liberty. The second series of *Poems and Ballads*, less hectic and sensual than the first, appeared in 1878.

During this period Swinburne's health was being continually undermined by alcoholism and by the excesses resulting from his abnormal temperament and masochistic tendencies; he experienced periodic fits, from which, however, his remarkable powers of recuperation long enabled him to recover quickly. In 1879 he collapsed completely and was rescued and restored to health by his friend Walter Theodore Watts (later Watts-Dunton, q.v.). The last 30 years of his life were spent at The Pines, Putney, under the guardianship of Watts, who maintained a strict regimen and encouraged him to devote himself to writing. During these years he published 23 volumes of poetry, prose, and drama; five written then, were published posthumously, and a mass of manuscripts remains unpublished. In 1909 he succumbed to pneumonia and died at Putney on April 10.

**Assessment.**—Swinburne is chiefly important as a lyric poet. His technical equipment and prosodic invention were extraordinary. The characteristic qualities of his verse are insistent alliteration, unflagging rhythmic energy, great variation of pace and stress, effortless expansion of a given theme, and evocative if rather imprecise use of imagery. His poetic manner is highly individual, and his command of word-colour and word-music remarkable. But too often the remorseless rhythms have, after a

BROWN BROTHERS

SWINBURNE

time, a narcotic effect, and a poem which begins by exciting the reader ends by fatiguing him. Swinburne has been accused of letting the sound take charge of the sense and of paying more attention to the melody of words than to their meaning.

Certainly, considering his voluminous output, he has surprisingly little to say. Although some subjects, in particular the sea, continued to call out the best in his genius, his most important works belong to the first half of his life. If Swinburne's poetry has a centre (which has been denied, notably by George Meredith), it is to be found in the idea of liberty. Emotionally this involved a departure from the usual modes of feeling; for Swinburne, pleasure was closely associated with pain, and in poems such as "Laus Veneris" (1866), "Anactoria," and "The Leper," he is clearly dealing with perverse forms of love. (It was this aspect of his work that appealed to the "decadent" writers of the 1890s.)

Swinburne was pagan in his sympathies and passionately anti-theist: his denunciation of the Deity in *Atalanta*, where he refers to "the supreme evil, God," was erased from her copy by Christina Rossetti, and among his best-known lines is that from the "Hymn to Proserpine": "Thou hast conquered, O pale Galilean; the world has grown grey from thy breath." His nearest approach to a positive philosophy is to be found in his poem "Hertha." Politically, Swinburne, under the influence of Mazzini and Victor Hugo, was attached to the cause of national liberation and republicanism, though in later years he became markedly more conservative. His hero worship of these two men was typical of his tendency to extreme allegiances; in literature he was similarly devoted to Blake—on whom he wrote an important volume of criticism (1868)—to Shelley, to Landor, and to Baudelaire. His elegies on the two last are among his finest works.

In *Atalanta in Calydon* and, less strikingly, if (with Jowett's assistance), more correctly, in *Erechtheus* (1876), Swinburne attempted to recreate in English the form and spirit of Greek tragedy; his understanding of the Greek tragic outlook, coupled with his lyrical powers at their finest, make *Atalanta* one of the most successful examples of its kind. His devotion to Shakespeare—his eloquent *Study of Shakespeare* appeared in 1880—and to the Elizabethan and Jacobean drama, of which he had an unrivaled knowledge, is reflected in the early play *Chastelard* (1865). This was the first of a trilogy on Mary, queen of Scots—a figure who had a peculiar fascination for Swinburne—and was followed by *Bothwell* (1874) and *Mary Stuart* (1881); these dramas are unactable, despite fine passages, and *Bothwell* in particular is inordinately long. Apart from *Atalanta*, which many consider Swinburne's masterpiece, his most successful long poem is *Tristram of Lyonesse* (published with other poems in 1882), which deals with Arthurian legend in a very un-Tennysonian way and in which the couplet is used with astonishing skill and variety. His novel, *Love's Cross-Currents*, first printed serially in 1877 as *A Year's Letters*, was published as a book in 1905; another novel, the unfinished *Lesbia Brandon*, appeared in 1952 (ed. by R. Hughes). Both are chiefly of interest for their autobiographical element and the light they throw on Swinburne's psychological abnormalities.

To those Victorians who did not regard Swinburne as blasphemous and depraved, he seemed, at the time of his early volumes, a poet to whom almost anything might be possible. His verse was intoxicating, both in its voluptuous vigour of movement and in its defiance of restraint and convention. Though his technical mastery remained, however, the promise was not fulfilled; Swinburne never, in any profound sense, matured. Whether it is correct to say, as Harold Nicolson has suggested (see *Bibliography*),

that he early became impervious to outside impressions and so suffered from arrested development, or whether the abnormalities of his early manhood and the seclusion of his later years isolated him too much from normal human experience, it remains true that his genius did not develop and his understanding did not deepen with the years. Hence his achievement does not do justice to his gifts; but he remains important both as the symbol of mid-Victorian poetic revolt and, in his own right, as a lyric poet of unsurpassed virtuosity.

**BIBLIOGRAPHY.**—*Editions, Correspondence: Poems*, 6 vol. (1904; often reprinted); *Collected Poetical Works*, 2 vol. (1924); *Complete Works*, ed. by T. J. Wise and Sir E. Gosse, 20 vol. (1925–27; the Bonchurch edition), including bibliography by T. J. Wise (vol. xx). The most complete collection of the letters is the Yale edition, by C. Y. Lang, 6 vol. (1959–62); vol. 6 includes a previously unpublished account of Swinburne's abnormalities by Gosse. Selections include *The Best of Swinburne*, ed. by C. K. Hyder and L. Chase (1937); *Selected Poems*, ed. by E. Shanks (1950).

*Biography and Criticism:* Sir E. Gosse, *The Life of A. C. Swinburne* (1917; revised as vol. xix of the Bonchurch edition); T. S. Eliot, in *The Sacred Wood* (1920); Sir Max Beerbohm, "No. 2 The Pines," in *And Even Now* (1920); T. E. Welby, *A Study of Swinburne* (1926); H. Nicolson, *Swinburne*, in the "English Men of Letters Series" (1926); G. Lafourcade, *La Jeunesse de Swinburne*, 2 vol. (1928) and *Swinburne: a Literary Biography* (1932); S. C. Chew, *Swinburne* (1929); C. K. Hyder, *Swinburne's Literary Career and Fame* (1933); H. Hare, *Swinburne: a Biographical Approach* (1940). (S. DE R. W.)

**SWINDON**, a municipal borough and parliamentary division of north Wiltshire, England, 78 mi. (125 km.) W of London by road. Pop. (1961) 91,739. Area 9.5 sq.mi. (24.6 sq.km.). Until 1841 it was a small market town (now Old Swindon) with a population of less than 2,000, but after the Great Western Railway had built its main engineering works to the north, the population rapidly increased to 45,000, and in 1900 it received its charter. More than 21,000 persons are employed in the railway works; other industries include engineering, clothing, and tobacco. Under the Town Development Act, 1952, provisional approval was obtained from the Ministry of Housing and Local Government to accept overspill population and industry from the Greater London area. Planning approval was given to expand the population to 92,000 within the existing borough boundaries and a 75-ac. trading estate was developed close to the Swindon-Gloucester railway. In 1947 the first municipally owned arts centre in the country was opened, combining a small concert hall, a stage, and an art gallery.

**SWINE**, a name applied to the domestic pig, but also used to include its wild relatives. The animals constitute the family Suidae. Swine originated in the Old World. The typical genus *Sus* is exemplified by the domesticated pig and the wild boar. See PIG; BOAR; ARTIODACTYL.

**SWINE FEVER (HOG CHOLERA)** is a devastating acute general infection of swine, caused by a virus, in which high fever and prostration are outstanding symptoms.

Natural infection results from immediate or mediate contagion. The disease may be acquired by healthy herds by the introduction of infected pigs. Exposure of swine in markets in infected areas is a common source of infection; so are vehicles and trucks in which pigs are conveyed from place to place; dealers, castrators who journey from farm to farm, and attendants may serve as agencies whereby contagion is conveyed. Outbreaks are likely to recur in premises where the disease has existed previously, as the virus appears to retain its vitality for fairly long periods outside the animal body.

Since the virus may persist in uncooked garbage, Canada, most of the states of the U.S., and Great Britain require that garbage fed to swine be sterilized by cooking.

After an incubation period of four days to three weeks after exposure, the disease is ushered in by fever. Subsequent symptoms vary somewhat with the form the disease assumes. The animal has no appetite, is depressed, ill, and separates itself from its companions; the conjunctivas are reddened and congested and may secrete a mucopurulent discharge; vomiting is common, and constipation and diarrhea are both met with; sometimes the feces become dysenteric and the odour is peculiar and disagreeable.

In many cases a skin rash develops, the parts principally involved being the region of the ears, the axilla, groin, and the skin

covering the abdominal area. The mucous membrane lining the mouth, fauces, and pharynx may become inflamed; later ulcers form and become covered with a diphtheritic exudation. As a result the animal is unable to feed and respiration is difficult. The lungs may be the seat of pneumonic changes.

When this is the case the animal then has a short, dry, and paroxysmal cough, a nasal discharge, difficulty in respiration, and the other symptoms characteristic of acute lung infection. Gastritis and enteritis are common. The animal lies about and is compelled to move does so reluctantly and sometimes with a staggering gait and an arched back; later it is unable to rise and becomes comatose.

As in other acute septicemic diseases, a hyperacute form may develop and death supervene within a few days; or a less acute form may set in, with one or more groups of organs becoming involved. Outbreaks are often complicated by secondary infection, particularly of the *Salmonella* type. A chronic type is also encountered, in which life drags on over a considerable period; the animal becomes more debilitated and emaciated and it remains a possible source of infection to other pigs. Recovery from the various forms of swine fever occurs in some cases, the virulence and the mortality varying widely in different outbreaks.

Swine fever is widely distributed in Europe, North America, and Africa. In countries where the disease must be reported, where infected animals are compulsorily slaughtered, and the premises quarantined, considerable control has been secured. In the U.S. the average loss from swine fever, including vaccination cost, was estimated in the 1960s to be about \$25,000,000 a year. In England compensation paid by the Ministry of Agriculture during the first two-and-a-half years of the eradication scheme was estimated at £5,460,000 (\$15,288,000). This covered full compensation for healthy animals and half value for pigs showing swine fever symptoms at the time of slaughter. Complete eradication by 1966 appeared probable.

In the U.S. control is mainly by modified and killed vaccines which are safer than the older method of simultaneous vaccination with a virulent swine fever virus and hyperimmune serum. In England and France vaccine is prepared from diluted defibrinated blood containing the swine fever virus inactivated with a solution of crystal violet in ethylene glycol. Pigs' blood is normally used but lapinized vaccine is popular in France. Crystal violet vaccine cannot be used on pigs incubating swine fever but will give immunity for about a year to healthy animals. Its use in England was discontinued in 1964 as part of the eradication scheme because it can mask swine fever symptoms in pigs carrying the disease. (A. R. S.; NA. BR.; X.)

**SWINTON AND PENDLEBURY**, a municipal borough of Lancashire, England, 5 mi. (8 km.) NW of Manchester, contiguous with Salford. Pop. (1961) 40,470. Area 5.3 sq.mi. (13.7 sq.km.). A great part of the Clifton rural area was added in 1933. Cotton spinning and weaving, coal mining, the manufacture of electric batteries, and engineering are the chief industries. The town hall was opened in 1938. Anciently parts of Swinton were held by the Knights of the Order of the Hospital of St. John of Jerusalem. Swinton and Pendlebury, incorporated in 1934, forms with Eccles the Eccles parliamentary division of Lancashire, returning one member.

**SWISS LITERATURE.** In language and literature Switzerland has always been closely linked with its neighbours—Germany (and Austria), France, and Italy—because, of the four national languages, only the Raeto-Romance dialect, Romansh, is peculiar to Switzerland. There is also a substantial quantity of Swiss dialect literature. Chronologically, literature in Latin precedes all the others.

In the following survey all these literatures are considered, both on their own account and as parts of Swiss literature in an overall sense. Many of the writers mentioned have separate articles which provide biographical information and further critical comment; these may be found most conveniently by consulting the Index. The articles GERMAN LITERATURE; FRENCH LITERATURE; ITALIAN LITERATURE; and RAETO-ROMANCE DIALECTS should also be consulted.

**Latin Swiss Literature.**—The oldest document relating to what is now Switzerland was not produced within its territory, for the first notable description of Helvetia and the Helvetii (*q.v.*) is to be found in the first book of Caesar's *Commentarii* (51 B.C.), commonly referred to as *Bellum Helveticum*. Among the Latin chronicles of the Middle Ages the *Casus Sancti Galli*, written by Ekkehard IV (d. 1060), a monk of St. Gallen (St. Gall), gives an impressive description of the highly developed culture of the Benedictine abbey of St. Gallen. Another chronicle, the *Johannis Vilodurani chronicon*, contains the world picture as seen by a Franciscan of Winterthur in the early 14th century. The Swiss humanists who expressed themselves in Latin devoted most of their prose and verse to description of their own country: e.g., Albrecht von Bonstetten (c. 1442–c. 1504), dean of the abbey of Einsiedeln, in his *Superioris Germanie Confederationis descriptio* (1479), and Heinrich Loriti Glareanus (1488–1563), in his *Helvetiae descriptio* (1514). An important position in the history of general linguistics is taken by the Zürich polyhistor Konrad von Gesner (1516–65), who in his *Mithridates* (1555) undertook a survey of all languages known to him. For three centuries the two volumes *De Republica Helvetiorum* (1576) by the Zürich theologian Josias Simler (1530–76) remained the standard work on the constitutional law and politics of the Swiss Confederation.

The final phase of Swiss literature in Latin belongs to the 18th century and is largely connected with natural science. An outstanding example is *Uresiphioites helveticus, sive itinera alpina tria* (1708), the description of Switzerland given by the city physician of Zürich, J. J. Scheuchzer (1672–1733), a prolific writer of geographical and historical works.

**German Swiss Literature.**—In quantity, the most important literature of Switzerland is written in German. It first flourished in the age of the *Minnesinger* (*q.v.*), of whom more than 30, i.e., practically one-fifth of those known, lived on what is now Swiss territory. The so-called Codex Manesse, the manuscript of *Minnesang*, or love lyrics, originated in Zürich, and was attributed to Rudiger Manesse (1224–1304) and his son (d. 1297) by J. J. Bodmer, who was the first to have the Codex printed in 1758. Gottfried Keller made the Codex the subject of one of his *Zürcher Novellen*, *Hadlaub* (1878). In this way the poetry of the *Minnesinger* has become part of the history of Swiss literature.

The first literary productions with national characteristics were popular ballads and chronicles. The ballads commemorate especially the great battles for freedom fought by the Swiss from the 13th to the 16th century. The most effective and influential of these is the ballad of William Tell (*q.v.*), which through its moral and political aspects maintained an important position as a narrative and as a play from the late 15th century onward. The chronicles, occasionally written for some local authority and often illustrated, flourished especially in Bern, Lucerne, and Zürich. The most famous chronicles, however, were those written by Johannes Stumpf (1500–1578), and by Gilg (Aegidius) Tschudi (1505–72), a leading magistrate of Glarus. The content of Tschudi's *Chronicon helveticum*, which deals with the period 1000–1470, was widely known after its completion in the 16th century, although it was printed only in 1734–36.

The Reformation activities of Huldreich Zwingli (*q.v.*) had only an indirect influence on literature. Zwingli himself wrote mainly in Latin. The so-called Zürich Bible of 1529 was soon replaced by the Luther Bible, which, by way of Luther's powerful and authoritative use of the German language, made for a closer connection between the writings produced in Switzerland and Germany. One of the most important results of the work done by Zwingli was that the Protestant majority of German-speaking Switzerland established a permanent connection with the Protestant parts of western Switzerland, and with Protestant countries abroad. Thus one of the earliest Swiss accounts of England was produced (c. 1550) by the Zürich pastor and lexicographer Josua Maler (1529–99), and in the 18th century the first German translations of Shakespeare (by C. M. Wieland and J. J. Eschenburg) were published in Zürich.

The beginning of 18th-century literature in German-speaking Switzerland is marked by the works of a Bernese poet, and the end

by those of a historian from Schaffhausen. The poetry of Albrecht von Haller (1708–77), especially "Die Alpen" (1732), helped to bring about a new poetic awareness in Germany, and belongs to the earliest specimens of German poetry appreciated in France. The most important work of Johannes von Müller (1752–1809), *Geschichten schweizerischer Eidgenossenschaft* (1786–1808), though a fragment, became the most representative piece of historical writing in German classicism and had a far-reaching influence on the style of historical writing. Between these two landmarks appears what is occasionally referred to as the Zürich school of criticism. Two members of this school, J. J. Bodmer (1698–1783) and J. J. Breitinger (1701–76), opposing the critical views of French rationalism and classicism, strongly promoted the appreciation of English literature (especially Milton's *Paradise Lost* and Thomas Percy's *Reliques*) in Germany. Their work started a revival of religious and national conceptions which had its special effect in the succeeding generations. Salomon Gessner (1730–88) had a European success with his revival of the idyll; for predominantly moral reasons J. C. Lavater (*q.v.*; 1741–1801) turned to physiognomy and became one of its innovators; J. K. Hirzel (1725–1803) surprised the reading public in 1761 with his description of the village Socrates, Kleinjogg. In importance, however, they were surpassed by J. H. Pestalozzi (1746–1827), who not only wrote the first village story in German, *Lienhard und Gertrud* (1781), but included in it the nucleus of his later meditations, covering the entire field of the nature and destiny of man.

In the 19th century international fame and critical estimate at home did not always concur. Thus *Der schweizerische Robinson* (*The Swiss Family Robinson*) (1812–27) by Johann David Wyss (1743–1818), and *Heidi* (1880–81) by Johanna Spyri (1827–1901) are examples of a worldwide success, though their purely literary merits were never considered very high in their native country. During the 19th century the significance of German Swiss literature gradually increased. Bern produced its greatest novelist in Jeremias Gotthelf (pseudonym of Albert Bitzius; 1797–1854), whose epic power was combined with a profound knowledge of human nature. The series of his great novels, most of which describe village life, opened with the *Bauernspiegel oder Lebensgeschichte des Jeremias Gotthelf* (1837) and ended in the year of his death with *Erlebnisse eines Schuldenbauers*. It was in fiction and poetry that the Zürich writers Gottfried Keller (1819–90) and Conrad Ferdinand Meyer (1825–98) achieved fame. Both realized their own possibilities and destinies comparatively late, a phenomenon frequently observed in the history of Swiss thought. Keller reached the first peak of his creative powers with *Der grüne Heinrich* in 1854, and Meyer with his verse epic *Hutten's letzte Tage* in 1871. Meyer drew upon the mountains and the princely courts of the past, and as a writer of fiction he immersed himself in the life and culture of the Renaissance. Keller's prose and poetry are full of genial humour and exuberance matching the quality of his fundamentally human attitude, and his love for his country takes many different forms, from hymns of praise to pungent social criticism. The importance of this period is further emphasized by the writings of the Basel historian Jacob Burckhardt (1818–97), whose statements about the past, present, and future have become increasingly impressive and valid. His greatest disciple was Heinrich Wölfflin (1864–1945), who continued and completed that part of his master's work which was interrelated with the history of fine arts.

Many 20th-century authors, guided by the Swiss distrust of one-sided attitudes, believe that the values of tradition and emancipation are not necessarily irreconcilable. Thus, novelists such as Hans Albrecht Moser (1882– ), Robert Faesi (1883– ), Arnold Kübler (1890– ), and Kurt Guggenheim (1896– ), and poets such as Urs Martin Strub (1910– ) aim at a sort of holism, an interpenetration of the forces of both the native country and the world at large. A similar universal humanism is an essential feature of the historical and literary essays of C. J. Burckhardt (1891– ), J. R. von Salis (1901– ), Fritz Ernst (1889–1958), Max Rychner (1897–1965), and Emil Staiger (1908– ), and the cultural studies of Hans Zbinden (1893– ). All are representative of a truly European Switzerland.

An appreciable minority holds to the values of rural contentment still current in the village and the small town. Heinrich Federer (1866–1928) and Alfred Huggenberger (1867–1960) are typical of this tradition. The playwright Cäsar von Arx (1895–1949), the novelist Meinrad Inglin (1893– ), and the Catholic poet Silja Walter (1919– ) likewise stress the conservative element in the new age of materialism and prosperity. Others furnish antidotes to the conventional order of things, and are alert to the stimulus of international thought. The anthroposophist Albert Steffen (1884–1963), for example, opened deeper vistas of the individual and of Far Eastern traditions. Marxist views have been expressed in the novels and short stories of Jakob Bührer (1882– ).

The last German Swiss poet of international repute was Carl Spitteler (1845–1924), who won the Nobel Prize in 1919 for his epics in verse and prose. Albin Zollinger (1895–1941) was the leading Swiss poet between World Wars I and II, and his bold use of intuitive imagery is a parallel to the new valuation of the unconscious by the Swiss psychologist C. G. Jung (*q.v.*). The two pre-eminent writers of the mid-20th century are Max Frisch (1911– ) and Friedrich Dürrenmatt (1921– ). Dürrenmatt's burlesque plays (*e.g.*, *Romulus der Grosse*, 1949; *Die Physiker*, 1962 [*The Physicists*, 1964]), already widely known, are expressions of a revolt proclaiming uncompromising sincerity and greatness against the mass mediocrity of the age. Frisch has established himself both as a distinguished novelist (*Stiller*, 1954, *I'm Not Stiller*, 1958; *Homo Faber*, 1957, Eng. trans., 1959), and as a successful dramatist (*Andorra*, 1961); his main subject is the complicated, skeptical modern individual.

**French Swiss Literature.**—Though the French-speaking part of the Swiss population is only one-fifth of the total, the literature it has produced carries considerably more than its proportionate weight. This is partly because of the immigration of a number of talented Huguenot families, partly, though to a lesser degree, because writers born in the German-speaking part of the country occasionally decide to express themselves in French. This applies especially to the Bernese.

The beginnings of French Swiss literature proper coincide with the Reformation. Calvin, who settled in Geneva in 1541, exercised his influence on French literature through his diction, as well as through his theology, and although Geneva did not join the Swiss Confederation until 1815, the "*cit  de Calvin*" was a constant influence on French Swiss literature. One of the first important studies of England in French was by the Bernese B.-L. de Muralt (1665–1749), whose stay in England in 1694 resulted in his *Lettres sur les Anglais et les Fran ais* (1725). His work was admired by Rousseau, another European figure connected with Geneva, where he was born. For Rousseau the influences were mutual: he was not only a *citoyen d'un  tat libre* ("citizen of a free state"), as he described himself in the opening chapter of *The Social Contract*, but obviously shared the political and psychological conceptions of all Switzerland to such a degree that one is tempted to consider him its most brilliant publicity agent (*see*, for example, his *Consid rations sur le gouvernement de Pologne*). Swiss subject matter was also dealt with by H. B. de Saussure (1740–99), one of the founders of modern geology, in his *Voyages dans les Alpes* (1779–96).

At the beginning of the 19th century French Swiss literature on the whole preferred international themes and was largely connected with the influential circle of Mme de Sta l (*q.v.*), who in her manor house at Coppet, on the Lake of Geneva, entertained many of the leading intellectuals of Western Europe. Mme de Sta l, like her friend Benjamin Constant (*q.v.*), is generally associated with the literature of France; however, both were of Swiss extraction, and much of their work was inspired by their background. Another member of Mme de Sta l's circle, the Genevan J. C. L. de Sismondi (1773–1842), made an important contribution to Italian history with his *Histoire des r publiques italiennes du moyen  ge* (1807–18). There was also K. V. von Bonstetten (1745–1832), whose outlook was fundamentally European, especially in *L'Homme du midi et l'homme du nord* (1824).

To a later development belong the humorous tales and sketches

of Rodolphe Toepffer (1799–1846), depicting a more homely world (*La Biblioth que de mon oncle*, 1832), while the poems of Juste Olivier (1807–76) testify to a pronounced patriotism (*Po mes suisses*, 1830). The criticism of Alexandre Vinet (1797–1847), based on an essentially personal interpretation of Christianity, found an echo in both Switzerland and France. Toward the end of the 19th century a powerful international influence was exercised by the posthumous publication of the fragments of H. F. Amiel's *Journal intime* (1883–84), which caused Tolstoi to write a moving preface for its Russian translation. In his historical writings Philippe Monnier (1864–1911), in a manner reminiscent of Jacob Burckhardt, deals with Italy in the 15th and 18th centuries (*Le Quattrocento*, 1901; *Venise au XVIII  si cle*, 1907). C. F. Ramuz (1878–1947) wrote strongly imaginative novels about life among vinegrowers and Alpine herdsmen. Gonzague de Reynold (1880– ) demonstrated the inward connection between German- and French-speaking Switzerland in the 18th century (*see Bibliography*), and depicted the whole of his country in his *Cit s et pays suisses* (1914–48).

As much of 20th-century literary activity is centred on the city and canton of Geneva, contemporary French Swiss literature has a cosmopolitan air, and it is often difficult to distinguish what is peculiarly Swiss—as, for instance, in the prose of Henry Vallotton (1891– ) and the poetry of Gilbert Trollet (1907– ). A typically European outlook is to be found in the essays of Denis de Rougemont (1906– ). More particularly Swiss themes are noticeable in the prose of Ramuz and L on Savary (1895– ).

**Italian Swiss Literature.**—Only about 9% of Switzerland's total population use Italian as their native language. Their home is in the canton of Ticino and in some of the southern Grisons valleys. It is thus unlikely that the literature of such a small group could exist without a strong and permanent relation to Italian literature proper. Since the 18th century there have been a few nationally distinct features in what is often called the Swiss Italianit . As an exponent of the Age of Reason, Father Francesco Soave (1743–1806) of Lugano translated John Locke and Salomon Gessner into Italian, and, following the example of the latter, wrote his own *Nouvelle morali* (1782–84), which have appeared in hundreds of editions and have made the story of William Tell popular in Italy. A representative figure in the first half of the 19th century is Stefano Franscini (1796–1857), who helped to bring about the new unity of the Ticino and to connect it with the spirit of the Swiss Confederation. His main work, *La Svizzera italiana* (1837–38), bears as a motto a quotation from Albrecht von Haller: "*Alpibus quidem ad Italiam spectantibus ego plurimum boni spero*" ("*The Alps looking toward Italy are my greatest hope*"). His *Nuova statistica della Svizzera* (1847) proved to be a particularly effective description of Switzerland in that period.

The most outstanding poet and novelist of the Ticino is Francesco Chiesa (1871– ). A convinced regionalist, he combines a profound love of his country with an admiration for the great Lombard poets. His vast influence on his contemporaries has contributed toward keeping the Italianit  of his region intact (*Caliope*, 1907; *I viali d'oro*, 1911; *Tempo di marzo*, 1925). One of his disciples, equally bent on exploring and interpreting his home country, was Giuseppe Zoppi (1896–1952) (*Leggende del Ticino*, 1928; *Presento il mio Ticino*, 1933). Italian-speaking Switzerland has also produced an eminent existentialist essayist and novelist in Felice Filippini (1917– ). Further contributions to Swiss literature include the scholarly essays of Piero Bianconi (1899– ) and Guido Calgari (1905– ), the fictional prose of Carlo Castelli (1909– ), and the poetry of Pericle Patocchi (1911– ), much of whose work is written in French.

**Raeto-Romance Literature.**—The Raeto-Romance dialect, Romansh, is used only in a few Grisons valleys. In 1776 a treatise by the Grisons historian and philologist Joseph Planta (1744–1827) was published in English by the Royal Society, making the existence of the language known to a wider public. Only in the 20th century, however, was it officially recognized: on Feb. 20, 1938, in a plebiscite of the whole country, Romansh, though represented by only 1% of the total population, was declared the fourth national language of the Swiss Confederation.

Raeto-Romance literature was in its origins predominantly ecclesiastical, and began in the Middle Ages. The Reformation gave it new life. In 1560 a fine translation of the New Testament was published; in 1679 the whole Bible was translated by J. A. Vulpus and J. Dorta. There is also a rich variety of popular songs, especially of the religious and political kind. Owing to its geographical distribution Raeto-Romance literature is essentially regional in character. Nevertheless, the anthologist Caspar Decurtins (1855–1916); the poets Peider Lansel (1863–1943), Jon Guidon (1892–), and Artur Caisch (1893–); and the prose fiction writer Giachen Michel Nay (1860–1920) achieved decidedly more than a merely local fame in the 20th century.

**Swiss Dialect Literature.**—The fortunes of Swiss dialect literature vary according to the language situation in each section of the country. In the Ticino, dialect literature is produced with much devotion, but has been of little consequence. In the French-speaking part of the country the local dialects are on the wane. The important instances of dialect literature there belong to the past, such as the Genevan ballads commemorating the victory of the *escalade* in 1602. International fame was achieved by the various *ranz des vaches* (melodies sung, or played on the alphorn, by herdsmen).

Dialect literature flourishes mainly in the German-speaking part of the country, chiefly because there the people, regardless of social rank and education, consistently use dialect for everyday purposes. The existence of numerous local idioms might even produce an ever-increasing variety of dialect writings. This, however, would be at cross-purposes with the determination of writers and readers to remain on common ground with German literature as a whole. Some of the best poets express themselves both in High German and in their dialect. Thus Adolf Frey (1855–1920) published a volume of poems in the dialect of the Aargau (*Duss und underm Rafe*, 1891), and Meinrad Lienert (1865–1933) wrote several poems in the dialect of Schwyz. Almost every canton has its *Mundaridichter*, or local poet. There are vigorous novels in the Bernese dialect, by Rudolf von Tavel (1866–1934), and Simon Gfeller (1868–1943). Schaffhausen is represented in the novels of Albert Bächtold (1891–); and Joseph Reinhart (1875–1957) wrote in the dialect of Solothurn.

**Patrimonium Helveticum.**—Without detriment to their connections with European civilization, many Swiss regard the existence of a manifold national literature with considerable satisfaction. Between the extremes of absolute diversity and absolute unity there is room for all aspects and expressions of thought and imagination. Since Switzerland has never had a representative cultural centre such as Florence once was for Italy and Paris still is for France—each group (and sometimes each individual writer) expresses itself according to its character and region. This may have its advantages, but it also has its dangers, which can only be overcome on the level of a vigorous national consciousness. So far this consciousness has proved adequate. A deteriorating structural change could occur only if the minorities were estranged from the confederate whole, or if the majority forces were tempted to exploit their position regardless of tradition.

Although the numerical relationship of the different languages is slightly shifting, there is no serious peril to the balance of the different cultures. On the contrary, because the underlying ideals are very much alive, they may produce further highlights of national integration. A development of more than 1,000 years is at the basis of Swiss literary life and will continue to shape what might be called an evergrowing *patrimonium Helveticum*.

(F. E.; H. SN.; A. Bx.)

**BIBLIOGRAPHY.**—*Anthologies*: R. Faesi, *Anthologia Helvetica* (1921), a collection of the six literatures mentioned. Anthologies based on each of the four national languages are: E. Korrodi, *Geisteserbe der Schweiz*, 2nd ed. (1943); C. Clerc, *Le Génie du lieu* (1929); A. Janner, *Scrittori della Svizzera italiana*, 2 vol. (1936); C. Decurtins, *Rätoromanische Chrestomathie*, 13 vol. (1888–1919). See also K. Bartsch, *Die Schweizer Mundesänger* (1886); L. Tobler, *Schweizerische Volkslieder*, 2 vol. (1882–84). **SWITHUN** (SWITHIN), SAINT (d. c. 862), Anglo-Saxon bishop of Winchester from about 852 to 861 or 862. Except for his profession to Ceolnoth, archbishop of Canterbury, and two attestations of genuine charters, nothing reliable is known of Swithun's life. In 971, on July 15, Aethelwold, bishop of Winchester, translated his body into the cathedral, after reports of miracles. Writers soon after this event, Wulfstan the preceptor of Winchester, Lantfrith "the foreigner," and the homilist Aelfric, could find nothing about his life, hence it is unlikely that the accounts in later writers, such as William of Malmesbury, which make him tutor to King Aethelwulf and a miracle worker in his lifetime, have any basis of fact. They claim that he wished for burial outside the church, where, according to William, "he would be exposed to the feet of passers-by and the drops falling from above," a remark which some have tried to connect with the weather superstition linked to his day. After 971 his cult spread widely and his name displaced those of St. Peter and St. Paul in the dedication of the cathedral.

The origin of the superstition that rain on his day, July 15, means rain for 40 days, is obscure. The tale that he sent rain to prevent the removal of his body is a modern invention; the earliest writers make him appear in a vision to urge this translation. The first evidence for a weather prophecy seems to be a 13th- or 14th-century entry in a manuscript at Emmanuel College, Cambridge: "In the daye of Seynte Svythone: rane ginneth rininge/Forti dawes mid ywone: lestez such tithinge" (On St. Swithun's day it begins to rain; 40 days usually lasts such a happening). Here, however, it is connected with the day of his death, July 2, not of his translation, July 15.

Earle, *Legends of Saint Swithun* (1861); *Willelmi Malmesbiriensis monachi gesta pontificum*, ed. by N. E. S. A. Hamilton (1870); letter in *The Times* (London), July 31, 1963, from P. Clemoes, F. Stubbings, and G. Evans. (D. Wk.)

**SWITZERLAND** (German SCHWEIZ; French SUISSE; Italian SVIZZERA; the Latin HELVETIA appears on the country's postage stamps) is a confederation or *Eidgenossenschaft* of 22 cantons (3 of which have half-cantons) with a republican and federal constitution. It is in Central Europe, bounded north by the Federal Republic of Germany, east by Austria and Liechtenstein (included since 1924 in the Swiss customs and monetary union), southeast and south by Italy, and southwest, west, and northwest by France. It forms an irregular-shaped mass with an area of 15,941 sq. mi. (41,288 sq. km.) of which the greatest length (west-southwest to east-northeast) is 226 mi. (364 km.), and the greatest breadth (north to south) is 137 mi. (220 km.). It has three major divisions: the Alps, the Mittelland (central plateau), and the Jura, which divide into numerous small regions, bound together as a political confederation, made originally for common defense. Of its area, 22.6% is unproductive (i.e., steep slopes, bare rocks, areas of permanent snow and ice, lakes, etc.), 24.8% is forested, 24.3% is alpine pasture, and only 28.3% is improved farmland.

The neutrality of Switzerland, established by the Congress of Vienna (1815), has served Switzerland well geopolitically and economically. It has made possible the establishment in Geneva

of headquarters for international good works (as the Red Cross), agencies, and organizations. The capital is Bern.

## I. PHYSICAL GEOGRAPHY

**1. Physiography.**—The country is drained by three great rivers, the Rhône, Rhine, and Aare, the first flowing west and the other two north from the central High Alps across the Mittelland. In addition, the southern canton of Ticino is drained by the Ticino from the St. Gotthard Massif southward to the Po, while in the extreme east a tongue of the canton of Graubünden (Grisons) drains northeast via the upper Inn Valley (Engadine) into the Danube. The Rhône and Rhine valleys are divided from that of the Aare by the great limestone ranges of the Bernese Alps (Oberland) and Tödi. The lower Aare Valley winds across the Mittelland to join the Rhine opposite Waldshut, but the upper Reuss, Rhine, and Rhône flow in wide glacially overdeepened trenches in the structural depression that separates the High Calcareous Alps from the Pennine Alps and the St. Gotthard Massif. The Pennine Alps provide the loftiest wholly Swiss summit (15,203 ft. [4,634 m.]) in the crowning Dufourspitze of Monte Rosa, though the Dom (14,911 ft. [4,545 m.]) in the Mischabelhörner, immediately north of Monte Rosa, is the highest entirely Swiss mountain mass. The Matterhorn (Italian Monte

Cervino, French Mont Cervin, 14,688 ft. [4,477 m.]), one of the best-known Pennine peaks, is on the Swiss-Italian border near Zermatt. The highest summit in the northern parallel ridge is the Finsteraarhorn (14,022 ft. [4,274 m.]) in the Bernese Oberland, while the lowest level within the Confederation is on Lake Maggiore (646 ft. [197 m.]).

The geological build of the Alps is exceedingly complex; the contorted, folded and overfolded sedimentary rocks have been fractured and eroded, exposing old crystalline cores at the surface; the Jura have a simple fold structure involving mainly Jurassic limestone. Much of the broken central plateau (Mittelland) is underlain by Oligocene and Miocene rocks, molasse outcrops in the Napf region. These Tertiary deposits are covered in many parts of the Mittelland by glacial and Recent deposits including moraines, sheets of boulder clay, fluvioglacial gravels, and peat.

The country drains to the North Sea (via the Rhine), the Mediterranean Sea (via the Rhône), the Adriatic (via the Ticino), and the Black Sea (via the Inn). Many rivers, because of their alpine regime, were once subject to seasonal floods which necessitated artificial embankment. The most important control scheme was that of Conrad Escher of Zürich (later Conrad Escher von der Linth) who in 1807-27 regulated the turbulent Linth above the Walensee, from which it emerges as the Limmat. An earlier (1714) successful work was the diversion of the torrential Kander into the Lake of Thun at Spiez, where it is now forming an extensive lake delta.

The Swiss lakes are numerous: the largest, Geneva (Lac Léman) and Constance (Bodensee), are on the French and German frontiers respectively and so are not wholly Swiss. Neuchâtel (83 sq.mi. [216 sq.km.]) is the largest all-Swiss lake. About one-fifth of Lake Maggiore (total area 82 sq.mi. [212 sq.km.]) at the northern end is Swiss; next in order of size are the lakes of Lucerne, Zürich, about half of the Swiss-Italian Lake of Lugano (19 sq.mi. [49 sq.km.]), the lakes of Thun, Brienz, Zug, Walensee, and Sempach; no others exceed 4 sq.mi. (10 sq.km.). Eleven of these lakes are in the Aare Basin; two (Maggiore and Lugano) are in the Po Basin, and the Lake of Geneva serves as a filter to the silt-laden Rhône as does the Lake of Constance to the Rhine. The beautiful chain of lakes in the upper Engadine includes the Sils (1.6 sq.mi. [4.1 sq.km.]), and the smaller, slightly lower lakes of Silvaplana and St. Moritz. Many small mountain lakes are of interest, such as the Riffelsee in which the Matterhorn is reflected; the picturesque Oeschinensee (5,190 ft. [1,582 m.] altitude) mirroring the snow-capped Blümlisalp; and the remarkable Märjensee (7,749 ft. [2,362 m.] altitude), fed by glacial melt-water so that its level is variable, while on it float miniature icebergs from the Great Aletsch glacier.

Of the countless waterfalls in Switzerland, those of the Rhine (near Schaffhausen), under 100 ft. (30 m.) high, inclusive of rapids, and several hundred feet wide, are the grandest; but the most beautiful are of less volume and greater height, such as those of the Lauterbrunnen valley and particularly the Staubbach, a mere veil of water falling over the ledge of a rock bench with a drop of 984 ft. (300 m.).

**Glaciation.**—Switzerland contains many glaciers that are relics of the Pleistocene alpine glaciation; the number is estimated at more than 1,000 but no exact computations are possible because of numerous detached ice masses which may or may not rank as glaciers. Practically all of them are in retreat, a process that has become speeded up in recent years, notably exemplified by the Rhône glacier. They probably occupy 700 sq.mi. (1,800 sq.km.), unequally distributed; half the cantons possess no glaciers. The greatest area of permanent ice is found in the Valais (over half the total area), followed by Graubünden and Bern (about one-sixth each); then by Uri, Glarus, and the Ticino. Longest glacier in the Pennine Alps is the Gorner (under 10 mi. [16 km.]), but it is exceeded by the Great Aletsch (around 15 mi.) and by the Fiescher and the Unteraar (around 10 mi. each) which occupy the upper eastern valleys of the Bernese Oberland.

**2. Climate.**—In an area such as Switzerland which extends through less than two degrees of latitude, climate is influenced

FIG. 1.—MAJOR PHYSICAL FEATURES OF SWITZERLAND

more particularly by differences of altitude, aspect, and slope; these show wide and sudden variations; *e.g.*, snow-capped Monte Rosa (15,203 ft. [4,634 m.] high) is only 30 mi. (48 km.) distant in a straight line from Lake Maggiore, where subtropical vegetation flourishes along its shores which are only 646 ft. (197 m.) above sea level. Great heights are characterized by decreased pressure of the atmosphere. Monte Rosa summit records about half sea-level pressure; hence the possibility of mountain sickness. High insolation, brilliant sunshine, and dry air, particularly in winter, produce sunburn and ice dazzle which may cause temporary blindness. Among the Alps the average fall in temperature is about 0.7° C (1.3° F) on the south side and about 0.5° C (0.9° F) on the north side for each 330 ft. (100 m.) of ascent. The height of the alpine crests and their main direction also influence the winds. In addition to local winds at certain higher levels where they show a daily change of direction (downslope in the morning, and upslope in the evening), there are other characteristic winds that are less localized in their effects, such as the southerly Föhn (warm, dry, and oppressive) which affects especially Swiss valleys trending south to north (*e.g.*, the Reuss), particularly during spring and autumn; and the northerly Bise, a cold wind experienced in the Lake of Geneva region and in the north-south trending valleys. Switzerland's many local climates are important, not only in "Europe's playground" but also in the high level sanatoria such as Davos, Leysin, and Sierre-Montana. Hence, weather statistics have been carefully compiled for many stations. January is the coldest month, the following means being recorded: Basel (Bâle) (909 ft. [277 m.] alt.) 0° C (32° F); Altdorf (1,480 ft. [451 m.]) 0.5° (32.9°); Davos (5,121 ft. [1,561 m.]) -7.2° (19°); St. Gotthard (6,877 ft. [2,096 m.]) -7.7° (18.1°); the Säntis (8,202 ft. [2,500 m.]) -9° (15.8°), while an unusually low average is at Bever (5,610 ft. [1,710 m.]

with -10° (14°). Annual precipitation (rain or snow) shows wide variations; *e.g.*, Basel has 32.5 in. (826 mm.); Altdorf, 49.0 in. (1,245 mm.); Davos, 35.7 in. (906 mm.); and the Säntis, 95.7 in. (2,430 mm.). On the Säntis the precipitation falls as snow from November to April inclusive, and only in July and August does rain predominate. Snow accumulates to a depth of 20 to 26 ft. (6-8 m.) at Bever and upward of 46 ft. (14 m.) on the Säntis. July is the hottest month, the average July records at Basel being 19° C (66.2° F), Altdorf 18° (64.4°), Davos 17° (62.6°), St. Gotthard 8° (46.4°), the Säntis 5° (41°), and Bever 12° (53.6°). The range of 22° C (40° F) at Bever tends to be extreme; the Säntis, though cold, is a more equable 14° (25°). The snow line, showing considerable local variations, lies at about 9,685 ft. (2,952 m.) on the western Alps which have heavy total precipitation and at about 10,500 ft. (3,200 m.) on the drier eastern Alps.

(See also ALPS.)

(W. A. B. C.; A. F. A. M.)

**3. Vegetation.**—The remarkable variations in climate and altitude, together with differences of geological substructure and soil formation, made possible a rich and manifold flora, most of which established itself after the postglacial period. A few hours' climb takes one from the warm temperate zone vegetation of the mid-European lowlands to arctic types. On the south side of the Alps the vegetation subsides to the boundary of the Mediterranean region, or in the Central Alps to the forested areas of southeastern Europe. Natural woodland once covered the whole country up to the timberline but because of clearing and cultivation it now occupies only about a quarter of the total land area. In wooded districts the basic flora stock is of Euro-Siberian origin but Atlantic types immigrated from the west, Mediterranean from the south, and Pontic from the east. Flora in the alpine regions has a preglacial, indigenous basic stock, mingled with additions

from the Arctic and sub-Arctic north, the mountains of Asia, and the Mediterranean area, all of which stem from the flora migrations in the Ice Age. There are about 2,600 phanerogamic and pteridophytic types, unevenly distributed. Particularly rich in interesting flora are the dry central alpine area, the southern foothills of the Alps and Jura, and the High Jura.

The widespread distribution of vegetation roughly follows the general climatic variations and the zones considerably overlap. The general distribution is as follows: (1) The low-lying districts by the Rhine and Lake of Geneva, the foothills of the Jura and the Alps, all of which have a mild climate. This belt supports mixed thermophilic deciduous trees (oak, hornbeam, elm, linden), vines, and walnut trees, good agricultural land, and parklands with ornamental trees from warmer areas. It extends from about 1,000 ft. to 1,600 ft. (300–500 m.) above sea level. (2) Immediately above this is a climax zone of beech and fir covering the main part of the Mittelland, the Jura, and the northern alpine valleys up to about 3,900 ft. (1,200 m.) with good arable and dairy farming land, and widespread plantations of spruce and pine. (3) A climatic zone comprising spruce forests with a moist, cool climate then reaches to the natural treeline which extends from the surrounding mountain chains toward the Central Alps at between roughly 5,250 and 6,250 ft. (1,600–1,900 m.). There, the matured soils are acid (podzolic brown soils or podzols) with acidophile flora, which becomes more and more stunted at higher levels of growth. Cultivation is negligible but there is well-developed cattle farming and lumbering. (4) Extending upward to about 7,000 ft. (2,100 m.) is the transition zone from the wooded levels to the alpine meadows. This lowest part of a treeless region is characterized by dwarf shrubs and extensive turf. On the acidic earths grow species of alpine rose (*Rhododendron ferugineum*), blueberry (*Vaccinium*), and dwarf juniper; on the better soils and limestone grow many kinds of dwarf plants and shrubs, another alpine rose (*Rhododendron hirsutum*), the green alder (*Alnus viridis*), and the mountain pine (*Pinus mugo*), the last being particularly common in the east. (5) The alpine meadows and turfs rise to the grass limit, which lies near the climatic snow line and in the Northern Alps at about 8,200–9,500 ft. (2,500–2,900 m.). The area serves only for pasture or hay making. The alpine meadows are transformed into brilliant gardens between May and July and stay so for all the summer. Among the first to blossom are crocuses, soldanellas, anemones, gentians, primroses, narcissuses, and violets. These are followed by rhododendrons, big monkshood and gentians, the celebrated edelweiss, bellflowers, rampions, louseworts, crowfeet, groundsels, oxeye daisies and other composites, dryas, lilies, saxifrages, pinks, the beautiful alpine Papilionaceae, and other flowering plants. The rarer ones are now protected.

The southern foothills of the Alps have a warm, humid climate and the natural vegetation on the limestone soils is rich in thermophilic deciduous trees of sub-Mediterranean types such as flowering ash, hop hornbeam, and various oaks and elms. On the acid silicate soils there are oaks, sweet chestnuts, and birches. Vines, maize (corn), southern fruits (fig, apricot, peach, Japanese medlar, persimmon), and vegetables are cultivated. Rich gardens and parklands with southern trees and shrubs are found. There are many types of foreign conifers, also acacias, azaleas, camellias, magnolias, and camphor, eucalyptus, bamboo, and ginkgo trees.

This oak-chestnut belt, which ascends to about 3,300 ft. (1,000 m.) is followed by a beech- and then a spruce-belt. The latter is characterized by the occurrence of larches, which mostly form the timberline at about 6,250 ft. (1,900 m.).

Essentially different types of vegetation are found in the inner alpine valleys of Valais and Graubünden. The predominant woodland tree in the lowlands is the Scotch pine, the rest is mainly oak and spruce, with fir woods in shaded corners of some valleys and beech in scattered areas. There are steep slopes on the sun side with steppe turf, consisting mostly of *Festuca valesiaca*, *Stipa pennata*, and other steppe-grasses and many beautiful flowering herbs. Cultivation at 1,600–5,600 ft. (500–1,700 m.) is dependent on irrigation. Products include wine, cereals, and fruits. In the higher subalpine stage, the woods consist of larches, mountain pine

and Arolla pine (*Pinus cembra*) with dwarf shrubs such as the *Rhododendron*, *Vaccinium*, willow, and spring heath. The timberline is high, in most places above 6,600 ft. (2,000 m.), and in the Engadine and in the southern side valleys of central Valais up to 7,500 ft. (2,300 m.). Upland cultivation at 4,300–5,000 ft. (1,300–1,500 m.) includes rye, barley, potatoes, and vegetables. The high alpine vegetation belts are similar to those in the Northern Alps but the flora is richer in rare species.

In addition to this climax vegetation there are plant associations which represent earlier stages in the development of localized vegetation. The woodlands, for example, are broken by a vegetation typical of marshes, moorlands, and meadows; in the high mountains there is vegetation typical of rocks and scree and many turf types different from the climax vegetation. This pioneer and transition vegetation is determined by local factors of climate and soil. It is widespread in the mountainous country, very diversified and rich in flowering species. If the soil matures and the climate is equalized, the vegetation changes to the climax and becomes much more monotonous in high regions. (WE. L.)

**4. Animal Life.**—Swiss fauna are mainly alpine but a mixture of species familiar to southern and north-central Europe is also found. Mammals include stoat, weasel, badger, otter, and fox. High in the mountains are the variable hare, marmot, and chamois. The alpine ibex, formerly a native but later hunted out of existence has been reintroduced. Bears and wolves, once common, are no longer found. The once familiar lammergeier or bearded vulture (native but now exterminated) only occasionally enters the country. On the higher slopes are several game birds, including the rock partridge. The alpine chough is still common, but as elsewhere in the world it is being ousted by the jackdaw. The honeybee is domesticated in large numbers. (MA. BU.)

## II. THE PEOPLE

**1. Characteristics.**—Etruscans, Celts, Germans, and Raetians have left their mark on Switzerland in the course of its historical evolution. The contemporary population shows mainly traces of the Alpine (brachycephalic, high curved occiput, brown eyes, dark hair), the "Nordic" (mesocephalic, blue eyes, fair hair), and the Dinaric peoples (brachycephalic, planoccipitalic, brown eyes, brown hair). (See also EUROPE: *Anthropology*.)

**2. Languages.**—By the constitution of 1874, German, French, and Italian were recognized as national languages for the purposes of debates in the federal parliament and for the public notification of federal laws and decrees. On Feb. 20, 1938, Romansh (spoken mostly in Graubünden) was recognized as a fourth national language (see RAETO-ROMANCE DIALECTS). The two main language groups follow a general homogeneous pattern and border on France and Germany. The Ticino and parts of Graubünden are Italian-speaking. In 1960, 69.3% of the resident population spoke German, 18.9% French, 9.5% Italian, 0.9% Romansh, and 1.4% other languages. The percentages, counting only Swiss citizens, were 74.4, 20.2, 4.1, 1.0, and 0.3, respectively. Apart from regional accents, there are also numerous Swiss-German dialects, classed under the general term "Schwyzerdütsch" and used on official and formal occasions, as well as socially.

**3. Religion.**—The constitution of 1874, while recognizing no established Swiss church, guarantees full religious liberty and freedom of worship, as well as exemption from any compulsory church rates. It repeats the 1848 constitution in forbidding the settlement of Jesuits and their affiliated societies in Switzerland. According to the 1960 census, Protestants comprised 52.8% of the population, Roman Catholics 45.4%, Old Catholics 0.5%, Jews 0.4%, and others 0.9%. Protestants outnumber Catholics in 11 cantons, of which 9 are German-speaking and 2 (Vaud and Neuchâtel) French-speaking. The Catholics outnumber the Protestants in 14 cantons, including 10 German-speaking, 3 French-speaking (Genève, Fribourg and Valais), and the Italian-speaking Ticino.

The Roman Catholic priests, who outnumber the Protestant clergy, total more than 6,000 under five diocesan bishops: viz., those of Basel-Lugano (resident at Solothurn), of Lausanne-Geneva-Fribourg (resident at Fribourg), of Sankt Gallen, of Sion

(Sitten), and of Coire (Chur). The Protestant churches are federated as the Schweizerischer Evangelischer Kirchenbund (Fédération des Églises Protestantes de la Suisse) which was founded (1920) in Olten.

#### 4. Customs and Culture.—

The Swiss character has been influenced by the country's relatively healthful climate, poor mineral wealth, widespread soil infertility, and the barrier of the Alps, broken only by a few easily usable passes. Having to limit themselves geographically, the Swiss were forced to restraint, sober reasoning, the calculation of advantages and disadvantages, and to a realism reflected also in the works of their writers, musicians, and artists. Customs and traditions flourish particularly in the alpine region, showing mainly in dress, alpine festivals, and popular games and sports. The last two include flag-throwing, *Schwingen* (wrestling), shooting, *Kegele* (bowling), *Hornussen* (throwing a stone with a string), and *Jassen* (card playing). Other facets are found in the music played on drums, the *Hackbrett* [dulcimer], the zither, the accordion, and wind instruments including the clarinet and the alpine horn), popular songs (*Jauchzen*, *Jodeln* [yodeling]), and shepherds' ballads. Swiss handicrafts such as wood carving (in the Bernese Oberland), hand weaving (Graubünden, Ticino), embroidery (northeastern Switzerland), and straw plaiting (Aare region, Ticino) are world famous. There are many forms of social activity, including youth clubs, guilds, and societies associated with the survival of certain traditions such as the carnival (Basel), and the *Sechseläuten*, a spring festival celebrated annually in Zürich.

FIG. 2.—THE CANTONS AND MAJOR LANGUAGE AREAS OF SWITZERLAND

### III. HISTORY

The prehistoric culture of the Celts (see CELT) in what is now Switzerland is described in the article LA TÈNE. By the end of the 1st century A.D. both the territory of the Celtic Helvetii (q.v.) in the west and the Celticized Raetia (q.v.) in the east, together with the Vallis Poenina (see ALPS, ROMAN PROVINCES OF THE) and Vindelicia (north of Raetia), had been attached to the Roman Empire. The Great Migrations (see EUROPE: History) brought the Germanic Alamanni (q.v.) to the northern regions in the 5th century A.D., while the Burgundians (see BURGUNDY) were settled on the western borders. Conquest by the Franks and the subsequent partitions of the Frankish Empire eventually led to the division of the country north of the Alps between the Duchy of Swabia (q.v.), which was a constituent part of the German Kingdom, and the last Kingdom of Burgundy. The union of the Burgundian crown to the German crown of Conrad II, in 1032, theoretically consolidated all the present Switzerland in the Holy Roman Empire (q.v.).

Geographical realities, however, made the subjection of the Alpine highlands difficult for any of their overlords to enforce; and the same realities made Swiss history very intricate and local. The present article must be chiefly concerned to outline (1) the drawing together of the various localities into a Confederation; and (2) the process whereby the Confederation, originally a league of three districts—or, as they are now called, cantons—with later members allied to those three but not necessarily to each other, was transformed into a federal state. The history of the various cantons prior to their connection with the Swiss League must be left to the separate articles on them.

The Holy Roman Empire comprised German-speaking, French-speaking, and Italian-speaking peoples, and the linguistic frontiers of all three converge in Switzerland. It was among the German Swiss that the movement of confederation started—not as one for independence from the Empire, but for mutual protection against the local House of Habsburg (q.v.). Only later, when the Habsburgs had secured the Imperial dignity as a practically permanent possession, was the severance of the Swiss Confederation from the Empire gradually realized.

**1. The Forest Districts and the Habsburgs, to 1273.**—The founder members of the Swiss Confederation were Uri, Schwyz, and Unterwalden (qq.v.), the so-called Forest districts, or cantons.

In A.D. 853 Louis the German, ruler of the East Frankish Kingdom, or Germany, granted all his lands in the *pagellus Uroniae*, or subdistrict of Uri, to the Abbey of SS. Felix and Regula (the later Frauenmünster) in Zürich. Immediately dependent on the *Reich*, this abbey was not to be subject to the authority of the counts of the surrounding Zürichgau, but was to be protected by a *Vogt* (advocate), or special representative of the king. The lands in Uri which Louis granted to it comprised most of the valley of the Reuss between the present Devil's Bridge and the Lake of Lucerne (the upper valley, or Urseren, belonged to the Abbey of Disentis, on the headwaters of the Rhine); and the privileged position of the Zürich abbey's tenants gradually led the other men of the valley to "commend" themselves to it, that is to say, to acknowledge its lordship. The office of *Vogt*, having been given to one family after another, gradually became hereditary; and in 1218 it was acquired by the Habsburgs.

The Habsburgs, established in the Swiss Aargau from the early 11th century, had held the countship of the Zürichgau from 1173. In this capacity they ruled, as the German king's representatives, over two districts adjacent to Uri, namely Schwyz (to the north) and Unterwalden (to the west), in both of which they also owned lands in their own right. Schwyz, however, which is first mentioned in 972, had a community of free men settled at the foot of the Mythen in the area east of Steinen; over this community the counts had immediate authority, whereas west of Steinen the people were under local lords. For Unterwalden, on the other hand, there was no free community either in Obwalden (the upper valley, around Sarnen) or in Nidwalden (the lower valley, around Stans): all the land was held by lay lords, such as the Habsburgs,

or by ecclesiastical lords, such as the abbots of Murbach in Alsace. Murbach, moreover, had founded the monastery around which the town of Lucerne (*q.v.*) grew up.

The German king Henry VII, of the Hohenstaufen dynasty, wishing to have control of the St. Gotthard Pass, bought back the *Vogtei* (official advocacy) of Uri from the Habsburgs in 1231, so that the valley thenceforward reverted to royal control. The Habsburgs, however, retained the Aargau and the Zürichgau; and their junior or Laufenburg line, to which the family possessions around the Lake of Lucerne passed on the partition of the dynastic inheritance in 1232, seems to have exercised its rights harshly. The free community of Schwyz in 1240 obtained a charter from the Hohenstaufen emperor Frederick II, placing it in immediate dependence of the crown, outside the jurisdiction of the counts; but the Habsburgs soon contrived to override this charter in practice.

When Pope Innocent IV excommunicated the emperor Frederick II and proclaimed his deposition (1245), Count Rudolf III of Habsburg-Laufenburg took the papal side. Not unnaturally, Schwyz, with Sarnen and Lucerne, rallied to Frederick's cause; and in 1247 these three places were threatened with excommunication if they persisted in upholding Frederick and in defying their Habsburg lord. The collapse of Frederick's cause soon brought these areas back under Habsburg authority. This interlude provides the only factual basis for later legends of Habsburg oppression. Uri had been on the papal side throughout.

In 1273 the rights of the Laufenburg branch of the Habsburgs in the Forest districts were ceded to the head of the senior, or Alsatian, branch of the family; and a few months later, in November, he was elected German king as Rudolf I (*q.v.*).

**2. The Everlasting League of 1291.**—Rudolf I, uniting in his person the characters of German king, count of the Zürichgau, landowner in the Forest districts, and head of the House of Habsburg, could be expected to exploit some of his functions in his personal interest. Though he recognized the privileges of Uri, he refused to acknowledge those of Schwyz. His royal grant of Austria and Steiermark (Styria) to his own sons (1282) did not immediately affect Switzerland, since the intervening countship of Tirol remained in the hands of its own counts; but on April 16, 1291, he precipitated a crisis by purchasing from the Abbey of Murbach (of which he was himself *Vogt*) all its rights in Lucerne and in Unterwalden for himself and his Habsburg heirs. This purchase threatened the communications of the Forest districts with the outer world by way of the Lake of Lucerne. On Aug. 1, 1291, a fortnight after Rudolf's death, when a struggle for the elective German crown was opening, the men of Uri, Schwyz, and Nidwalden formed the Everlasting League for self-defense against all who should attack or trouble them. This league, which was expressly stated to be a confirmation of an earlier one, was the foundation of the Swiss Confederation. Though Obwalden is not mentioned in the text of it, its name was later added to the appended seal of Nidwalden.

The League supported the anti-Habsburg candidates in the contest for the German royal succession. Uri and Schwyz allied themselves with Zürich on Oct. 16, 1291, and joined a general rising in Swabia against Rudolf's eldest son, Albert of Habsburg. Though the rising failed, Albert did not then obtain the German crown, which in 1292 went to Adolf of Nassau. In 1294 the first recorded meeting of the *Landsgemeinde* (legislative assembly) of Schwyz took place; and in 1297 King Adolf confirmed Frederick II's charter of 1240 not only for the free men of Schwyz but also for Uri.

In 1298 Adolf was overthrown by his Habsburg rival, who became German king himself as Albert I. Albert's rule was strict, but not oppressive: stories of his tyranny in the Forest districts date from two centuries later. Though he did not confirm the charters, he neither attacked Uri's ancient privileges nor abused his rights as king and count in Schwyz; and his appointment of a common administrator for Obwalden and Nidwalden (1304) was a step toward the unification of Unterwalden.

Albert's successor, the future emperor Henry VII, of the Luxembourg dynasty, on June 3, 1309, confirmed the charters of 1297

for Schwyz and Uri and also confirmed the liberties allegedly granted by Albert to Unterwalden, though in fact none had been granted. This act and the nomination of one bailiff to administer the three districts put them all in an identical political position, and that the most privileged yet given to any of them—the freedom of the free community of Schwyz.

**3. Morgarten and Brunnen.**—On Henry's death in 1313 the men of Schwyz seized the opportunity to attack the great Abbey of Einsiedeln, with which they had a long-standing quarrel as to rights of pasture. The abbot caused them to be excommunicated and Leopold's elder brother Frederick of Habsburg (chosen German king, as Frederick III, by a minority of the electors), who was the hereditary advocate of the abbey, placed them under the ban of the Empire. His rival, Louis IV the Bavarian, to whom they appealed, removed the ban; whereupon Frederick issued a decree restoring to his family all its rights and possessions in "the three valleys" and in Urseren and entrusted Leopold I of Habsburg with the execution of this order. The Confederates hastily made arrangements with Glarus, Urseren, Arth, and Interlaken to protect themselves from attack on every side.

Leopold collected a splendid army at the Habsburg town of Zug in order to attack Schwyz, while a body of troops was to take Unterwalden in the rear by way of the Brünig Pass. On Nov. 15, 1315, Leopold moved forward along the shore of the Lake of Aegeri, intending to assail the town of Schwyz by climbing the slopes of Morgarten above the southeastern end of the lake. There his army were awaited by a force of the Confederates, which utterly defeated it. Leopold fled to Winterthur, and the attack by way of the Brünig was driven back by the men of Unterwalden.

On Dec. 9, 1315, representatives of the victorious highlanders met at Brunnen, on the Lake of Lucerne, and renewed the Ever-

THE BATTLE OF MORGARTEN, 1315. ILLUMINATION FROM THE "PRIVATE BERNER CHRONIK" BY DIEBOLD SCHILLING, 1484

lasting League. In their main lines the documents of 1291 and 1315 are very similar, the later one being chiefly an expansion of the earlier. That of 1315 is in German (whereas that of 1291 is in Latin) and has one or two striking clauses largely indebted to a decree issued by Zürich on July 24, 1291. None of the three districts or their dependents was to recognize a new lord without the consent and counsel of the rest. Strict obedience in all lawful matters was to be rendered to the rightful lord in each case, unless he attacked or wronged any of the Confederates, in which case they were to be free from all obligations. No negotiations, so long as the *Länder* (territories) had no lord, were to be entered on with outside powers, save by common agreement of all.

Louis the Bavarian solemnly recognized and confirmed the new league in 1316; and in 1318 a truce was concluded between the Confederates and the Habsburgs. The lands and subjoined rights belonging to the Habsburgs in the Forest districts were fully recognized as they had existed under Henry VII, and freedom of commerce was granted. But there was no word about the political rights of the Habsburgs as counts of the Zürichgau and of the Aargau.

The renown won at Morgarten by Schwyz, which had always been foremost in the struggle, led to the informal application of the name Sweicz (modern German Schweiz; i.e., Switzerland) to the three Forest districts collectively as early as 1320. This name was extended to the Confederation as a whole, still informally, in 1352.

**4. Accessions to the League, 1332-64.**—In the aftermath of Morgarten, new members were admitted to the privileges of the original alliance of the Forest districts. The first to join was Lucerne, on Nov. 7, 1332, bringing a new, urban element into the association of pastoral communities and assuring its control of all the shores of the Lake of Lucerne. Next, on May 1, 1351, came the ancient town of Zürich (*q.v.*), when it was in fear of an attack by the Habsburgs. The League was thus advanced from the uplands to the plains; but the treaty of 1351 did not bind Zürich so closely as the other Confederates, so that later Zürich could occasionally incline to the Habsburgs in a fashion detrimental to its allies' interests.

The Habsburg Albert II of Austria began war against Zürich. This prompted the admission of Glarus and of Zug (*qq.v.*) to the League in 1352. Glarus, belonging to the Abbey of Säckingen (on the Rhine between Basel and Constance), refused to submit to the Habsburgs as *Vögte* of Säckingen and welcomed the aid sent by the Confederates; but its treaty of admission gave it an inferior status in the League, whose other members it was obliged to obey. Zug was abandoned by its Habsburg masters when the Confederates attacked it. Peace settlements, however, later in 1352 and, after a further crisis, in 1355, restored Glarus and Zug to the overlordship of the Habsburgs, who also regained their proprietary rights of 1291 in Lucerne.

These reverses were offset by the accession of Bern (*q.v.*) to the League on March 6, 1353, as the ally of the three Forest districts. Since the death of its founder, Berchtold V of Zähringen, in 1218, Bern had been an Imperial city, or free town of the *Reich*. Already in 1323 it had made a treaty with the Forest districts, but in 1352 had been forced to take part in the war against Zürich. Bern's membership was especially significant because it spread the League westward to the frontiers of Vaud, a Romance-speaking country then dominated by the House of Savoy (*q.v.*).

The Habsburgs in 1363 augmented their main seat of power, in Austria, by the acquisition of Tirol, which meant a very considerable advance into the Alpine region from the east. Despite this, the men of Schwyz, in 1364, by a bold stroke, won Zug for the League, of which it was thenceforward a permanent member. The Habsburgs acknowledged this conquest under a truce of 1368.

**5. Sempach and Näfels.**—Relations between the League and the Habsburgs soon deteriorated. The decisive conflict broke out in the time of Leopold III (1351-86), who under the partition of the Habsburg lands in 1379 received Steiermark, Kärnten (Carinthia), and Tirol and proceeded to reassert his family's authority over its western lands. Lucerne was particularly ag-

LUCERNE BECOMES THE FIRST TOWN TO JOIN THE EVERLASTING LEAGUE

16th-century illumination from the *Amtliche Luzerner Chronik* shows citizens taking the oath on the Weinmarkt, 1332

grieved at the demand for payment of customs to their bailiff at Rothenburg (a stronghold to the north of the town). The town refused to pay these dues and further irritated Leopold by granting citizenship to many of his own subjects, who could thus escape from his control. Finally the men of Lucerne attacked Rothenburg (1385); and this action, together with the grant of citizenship to the people of Sempach, provoked Leopold to war. With 6,000 men he advanced to crush Lucerne, which, with the Forest districts, raised about 1,600 men to oppose him. In the Battle of Sempach, on July 9, 1386, the Confederates were victorious, and Leopold himself was killed.

In October 1386 a truce was made, but Glarus, which had risen in revolt against the Habsburgs after Sempach, continued fighting. Then Leopold III's elder brother, Albert III of Austria, led an army against Glarus. On April 9, 1388, the men of Glarus, with help from Schwyz, defeated him in the Battle of Näfels.

The seven-year Truce of Zürich, made in April 1389, secured the Confederates in all their conquests. After a period of tension in 1393, when the Zürich council adopted a policy of neutrality in case of war between other Confederates and the Habsburgs, the general truce was prolonged for 20 years on July 16, 1394, with various stipulations which consummated the success of the League. Glarus was released from Habsburg rule on payment of £200 annually (1394); Zug too was released; Schwyz got the *Vogtei* of Einsiedeln; Lucerne got the Entlebuch, Sempach, and Rothenburg; Bern and Solothurn (*q.v.*), which had been allied with Bern since 1295, were confirmed in all their conquests. Above all, the Confederation as a whole was relieved of Habsburg overlordship. The rights of the Habsburgs as landed proprietors, however, were expressly reserved: Bern and Zürich in fact were empowered to call on the other Confederates for armed support to maintain those rights.

By the end of the 14th century the League comprised Schwyz, Uri, Unterwalden, Lucerne, Zürich, Bern, Glarus, and Zug. However, the five latter members were allied, not with one another, but only with the three original members, the Forest districts.

**6. The First Italian Conquests and the Aargau.**—The treaty of 1394, though it was technically just a truce, freed the League from fear of the Habsburgs. Both it and its individual

members could thus take the offensive to expand their territory. Uri perforce looked to the south, toward Italy. In 1403, therefore, Uri and Obwalden, in violation of the rights of the Duchy of Milan, together occupied the Val Leventina or Livinental, that is, the narrow valley of the upper Ticino River south of the commercially and strategically important St. Gotthard Pass; and in 1410 Uri finally annexed the Urseren Valley, thus obtaining complete command of the pass. Likewise in 1410, Uri and Obwalden, in dispute over pasturage with the local lords of the Val d'Ossola (Euchenthal) south of the Simplon Pass, appealed to the other members of the League for a joint occupation of that valley, which was achieved with the cooperation of all except Bern.

North of the Alps, Appenzell and the town of Sankt Gallen (*qq.v.*), after a decade of troubles, entered in treaties of *combourgeoisie* or reciprocal citizenship, with all the members of the League except Bern, in 1411 and 1412 respectively.

In 1412 the treaty of 1394 between the League and the Habsburgs was renewed for 50 years. Consequently, when the German king and future emperor Sigismund put Duke Frederick IV (1383-1439) of Tirol and Farther Austria under the ban of the Empire in 1415, the League hesitated to take action against Frederick till Sigismund declared that the treaty of 1412 did not release the Swiss from their obligations to the Empire. Then, in Sigismund's name, the several members of the League overran the extensive Habsburg possessions in the Aargau. The chief share fell to Bern, but certain districts (known as the *Freie Ämter* and the County of Baden) were joined together and governed as bailiwicks held in common by all members of the League (save Uri, basied in the south, and Bern, which had already secured the lion's share of the spoil for itself). This is the first case in which the League as a whole took up the position of rulers over districts which, though guaranteed in the enjoyment of their old rights, were politically unfree.

Meanwhile the Confederates had lost the Val d'Ossola to Savoy in 1414. They recovered it in 1416, thanks partly to alliance with the men of the Upper Valais (to the west of the Val d'Ossola; see VALAIS), who were then fighting for their own freedom. Next, in 1419, Uri and Obwalden bought from its lord the town and district of Bellinzona, at the end of the Val Leventina. This rapid advance, however, alarmed the duke of Milan, Filippo Maria Visconti; and the Confederates were not at one with regard to these southern conquests. Filippo Maria exploited the differences of the Confederates and reconquered Bellinzona and the valleys in 1422. Finally in 1426, by a large payment of money and the grant of certain commercial privileges, he obtained the formal retrocession of the Val Leventina, the Val d'Ossola, and Bellinzona.

**7. The Old Zürich War.**—Divergences of policy or of interest between the members of the League, largely the result of contrasting social conditions, had been accentuated not only with regard to the Italian conquests but also in the partition of the Aargau. They came to a head, in the so-called Old Zürich War, over the question of the Toggenburg succession.

Frederick VII, count of Toggenburg, the last great feudal lord in the area south of Lake Constance, possessed not only the Toggenburg or Upper Thur Valley but also Uznach (near the eastern end of the Lake of Zürich). Sargans and the upper valley of the Rhine from Sargans to the latitude of Feldkirch, the Prattigau (extending southward from the Rhine above Sargans), and the Davos Valley (at the farther end of the Prattigau). To protect this vast inheritance he had made treaties with members of the League, but on April 10, 1436, he died leaving no male heir.

Frederick's death was the signal for strife. While the Prattigau and the Davos Valley constituted themselves as the League of the Ten Jurisdictions at Chaux-de-Schwyz (supported by Glarus) and Zürich (backed by Frederick's widow), disputed the other territories. The other Confederates generally favoured Schwyz, to which some of them even sent military help, and Zürich, after two defeats, was forced in 1440 to make concessions. Zürich, however, was not resigned to this settlement and, in 1442, had recourse to alliance with Habsburg Austria, whose head, the future emperor Frederick III, had become German king in 1440.

Zürich's alliance with Austria, though it was permissible ac-

cording to the terms of Zürich's accession to the League, infuriated the other Confederates. They all joined in war against Zürich, whose troops were completely defeated at St. Jakob der Sihl, just outside the city (July 1443). Next year Zürich itself was besieged. Unable to get help elsewhere, King Louis XI procured from France the dispatch of 30,000 mercenary troops—the so-called Armagnacs—under the dauphin Louis (see LOUIS XI). This ravaging army advanced across Alsace and then tried to capture Basel (*q.v.*), a free Imperial city which was allied to Bern and Solothurn. At St. Jakob an der Birs, outside Basel, a detachment of Confederate forces, not more than 1,500 strong, put up a desperate resistance to the Armagnacs (Aug. 26, 1444), before being completely defeated. Louis abandoned his enterprise soon afterward.

Hostilities between the Confederates on the one hand and Zürich and Austria on the other continued till 1450; then peace was made by arbitration. Zürich abandoned the Austrian alliance and recovered nearly all the lands which the Confederates had occupied.

(W. A. B. C.; H. N.; X.)

**8. Sigismund of Tirol and the Burgundian War.**—After the Zürich War members of the League made new agreements with the abbot of Sankt Gallen (1451), with Appenzell (1457), and with the citizens of Sankt Gallen (1454); and an alliance with the Imperial city of Schaffhausen was also concluded (1454). In 1458 a quarrel broke out with Sigismund of Tirol, the emperor Frederick's cousin, who had succeeded to the Habsburg lands on the upper Rhine and in Alsace on the death of his father, Duke Frederick IV, in 1439 (in the 1440s the German king had been acting as his guardian). Temporarily allayed in 1459, the quarrel was revived in 1460. The members of the League, except Bern, thereupon seized the Thurgau, which was ceded to them as a common lordship in 1461. Rottweil, an Imperial city in central Swabia, allied itself to the League in 1463; and Mulhouse, in the midst of the Sundgau (Habsburg Alsace), made an alliance with Bern in 1466. War between the League and Sigismund over Mulhouse and the Sundgau ensued in June 1468 but was ended in August by the Treaty of Waldshut. By this, Sigismund undertook to pay an indemnity of 10,000 gulden within a year, failing which he was to forfeit Waldshut (at the Rhine-Aare confluence) and his Black Forest possessions to the League.

Sigismund had no ready cash, and his efforts to obtain a loan led to a more serious war. By the Treaty of Saint-Omer, in 1482, Charles (*q.v.*) the Bold, duke of Burgundy, offered 50,000 *écus* in cash against the pledge of Habsburg Upper Alsace, the county of Ferrette, the Black Forest lands, and some Rhenish towns. Interpreting some permissive clauses of the treaty favourably to his own expansionist ambitions, Charles proceeded to occupy Upper Alsace. He appointed Peter von Hagenbach as his agent with instructions designed permanently to unite Alsace with the Burgundian territories. This threatened the Empire, and Frederick III declared the treaty void; it also greatly perturbed Bern, whose prospects of expansion were much reduced. Further, Charles the Bold was negotiating alliances with Savoy and with Milan and was also threatening to occupy Mulhouse.

One result was the formation of the Lower Union in 1473 by Basel, Colmar, Mulhouse, Sélestat, and Strasbourg, a defensive association against the Burgundians. Another result was the Perpetual Understanding of March 30, 1474, between Sigismund of Tirol and the Swiss, by which the former renounced any territorial claims in Switzerland in return for promises of money to pay off his debts. This Perpetual Understanding was a definite peace superseding the system of truces begun in 1389 and renewed in 1394 and in 1412.

Hagenbach was illegally arrested and executed in the spring of 1474—a deliberate act of defiance of Charles the Bold, who seemed to be fully occupied elsewhere. The Lower Union, supported by Bern, attacked Héricourt, beyond the southern frontier of Alsace, in November 1474; and Charles's great-grandson, Louis XI of France, promised cash subsidies when the war continued. Inspired by Niklaus von Diesbach, the Bernese advanced still farther in 1475, taking not only Blamont (east of Héricourt) but also a large number of places in Vosges.

and areas round Lake Neuchâtel, including Grandson, Orbe, Jougne, Morat, Avenches, Estavayer, and Yverdon, which belonged to Savoy. The inhabitants of the Valais collaborated with Bern to prevent any interference from Milan.

and even a little alarmed, Charles the Bold came south in 1476, occupying Grandson at the end of February and its Bernese garrison. Bern had gathered a considerable force from many states of the Confederation and from the Lower for the relief of the castle: too late to effect this, they battle on March 2 at Grandson. Charles's faulty general in the face of a disciplined force of pikemen, whom he degraded as ignorant peasants, led to the rout, but not to the destruction of the Burgundians. The duke regrouped his forces at and again advanced against Bern in June. His way was blocked by the castle of Morat, held by Adrian von Bubenbergs Bernese. The threat to this position was sufficient to 20,000 Swiss to its defense; and the Battle of Morat (June 1476) ended in a complete Swiss victory.

Charles was defeated and killed at Nancy, in Lorraine, on Jan. 5, 1477. His inheritance was disputed between his daughter Mary II of France. Savoy regained, with French help, much of the

**The Convention of Stans: Fribourg and Solothurn.**—Community as the Swiss had so far enjoyed had been based almost entirely on successful defense against external enemies, but their prowess, nurtured by necessity, had made them potentially a threat. The latter part of the 15th century was the golden age of the mercenary soldier, and the Swiss had proved themselves the best available recruits. There was much money to be made by military service, and for the first time, prospects of lucrative employment opened to young men of valour. But the cessation of danger from abroad and the lure of foreign gold were almost sufficient to turn the states into competitors. There was no constitution to bind them together, no common officers, seal, lawcourts, coinage, and there was a growing divergence of interest between the urban and the mountain dwellers, as well as between east and west; there were numerous family feuds and endless local jealousies, leading in disputes about the distribution of the booty taken in the Burgundian War and about the administration of the territory held in common, particularly the Thurgau.

Fribourg and Solothurn (*qq.v.*) were anxious to come within the fold of the Confederation, but neither Zürich nor Lucerne were anxious for their support, while the rural members were determined to maintain their numerical predominance over the cities. Differences had become so exacerbated that all common action seemed at an end and civil war threatened. It was averted by intervention at Stans of the mysterious hermit (Nikolaus von Flüe, or Bruder Klaus [1417-87]; beatified 1669 and canonized 1947), who arranged a compromise which held the Confederation together. By the Convention of Stans the full sovereignty of the component states was maintained and reasserted, and they agreed to abstain from any separatist activity among themselves of any other state; to renew the oath of union every five years; and not to be captured in war without the participation of the participants in the war, but lands occupied by the victors to be shared equally by the vanquished. Ancient guarantees of mutual aid and assistance were renewed, and Fribourg and Solothurn were admitted as full sovereign members of the Confederation.

**10. Waldmann's Zürich.** Zürich had grown steadily in power and influence since the 1440s. Its textile manufactures had increased and with them the influence of the guilds, which shared effective authority in the city with the ancient aristocracy, the *Consfasel*. Hans Waldmann (1436-89) was recruited to the guilds by apprenticeship and to the aristocracy by marriage; he took part in a number of campaigns, including the Battle of Morat, and was equally successful in war, business, diplomacy, and politics. Burgomaster in 1482, he became virtual dictator of the city, upholding the interests of the citizens against the peasants and turning the city itself into a community whose welfare, amusements, food, and clothing were subjected to regulation and supervision. In 1489, however, Waldmann had to face an armed peasants' revolt, which led to a constitutional revolution and to his execution. The aristocracy of birth and of labour joined hands, and the possibility of Zürich's dictatorship extending to the Confederation was averted. The struggle between the government and the peasants, however, was repeated with local variations in Schwyz, Unterwalden, Zug, Lucerne, and Sankt Gallen, although in no instance did the country people secure all their hopes.

**11. The Emperor Maximilian.**—The temporary eclipse of Zürich was followed by the last attack from the north. The emperor Maximilian I (*q.v.*), Frederick III's son, husband of Mary of Burgundy and also, from 1490, the successor of the retiring Sigismund of Tirol, sought to extend alike the Imperial prerogatives and the possessions of his House. In 1495 the Imperial Diet of Worms had put forth a revised constitution for the Empire ensuring internal peace and common taxation and setting up an Imperial Chamber (*Reichskammergericht*) as a final court of appeal. The Swiss communities were technically Imperial subjects and had reason to fear renewed Habsburg aggression. They were therefore anxious to renew the understanding with France—Charles VIII was opposing Maximilian in Italy and was ready to hire Swiss mercenaries—and unwilling to join the Habsburg-sponsored Swabian League for the maintenance of peace.

In the ancient Raetia to the southeast of the Confederation's territory there were many small communities, which had formed three leagues: the League of God's House (*Gotteshausbund*) of 1367; the Upper or Gray League of 1395, which eventually gave its name, in the form *Graubünden* (*q.v.*) or Grisons, to the whole area; and the League of the Ten Jurisdictions, or of the Ten Courts (*Zehngerichtenbund*), of 1436, mentioned above as arising from the Toggenburg succession. The last named was allied to the first from 1450 and to the second from 1471; and the Upper League and the League of God's House allied themselves to the Swiss Confederation in 1497 and 1498 respectively. In 1499 a boundary dispute between Tirol and the League of God's House had led to a Tirolese incursion into the Engadine and the Munstertal and thus to war with Maximilian: the Swiss came to the help of their ally, the emperor took up the implied challenge, and in the so-called Swabian War or Swiss War of 1499 there was fighting from Basel to Bormio. Battles raged at Hard, Bruderholz, Schwaderloh, Frastanz, and, most notably, against Maximilian himself at Dornach. Everywhere Maximilian, as usual, was unsuccessful; and the Peace of Basel, on Sept. 22, 1499, mediated by Ludovico Sforza (il Moro) of Milan, ended the war. In fact, although not in name, it was the recognition of Swiss independence.

**12. Basel, Schaffhausen, and Appenzell Admitted.**—Basel as a member of the Lower Union had taken part in the Burgundian War and had learned the value of Swiss cooperation: as an Imperial city it evaded with difficulty an obligation to support Maximilian in the Swabian War, while the Confederates obviously needed security in the northwest. The bishop of Basel was politically much less influential than he had formerly been; and on July 13, 1501, the state was admitted to the Confederation. It was a notable addition, for the city was well fortified, strong, relatively wealthy, a home of scholarship with an active university and with an industrious and busy population.

Schaffhausen, although smaller, was in much the same position: it had had much difficulty with local knightly landlords; it had sent men to help its Swiss neighbours since 1453 and been accepted by most as an ally; and it had firmly refused to join the Swabian

League. It received the reward of full admission to the Confederation on Aug. 10, 1501.

Finally, on Dec. 17, 1513, Appenzell, which had been an ally rather especially closely associated with the Confederation, was admitted to full membership and partnership. It was the last addition to the whole body, now 13 independent states, until the French Revolution, and it was accepted only because it helped to redress the balance of the "country" as against the "city" members.

**13. The Milanese Campaigns.**—The northern frontiers of the Italian states, especially Milan, were exceedingly ill defined. The southern route through Uri over the St. Gotthard was of growing importance for trade and much used by the mercenaries hired for service in Italy. The inhabitants of the Val Leventina, into which Uri had made a new incursion as early as 1440, had renounced their allegiance to Milan in 1475, during the Burgundian War; and they had been upheld in 1478 by armed men from Uri and other Swiss states, who then failed to take Bellinzona but defeated a much larger Milanese force at Giornico. Bern and the western Confederates on the other hand were not interested in this southward expansion and refused to support any further advances; and it was with some difficulty that in April 1503 Bellinzona and the Blenio valley were secured by Uri, Schwyz, and Nidwalden from Louis XII (*q.v.*) of France, as duke of Milan, in return for help against Ludovico il Moro. There was, however, growing resentment felt at the expenditure of Swiss lives in fighting on behalf of strangers, and opinion was markedly divided about the continued value of the French alliance, especially when France controlled Milan.

The greatest man in the Valais was Matthäus Schiner, bishop of Sion and a cardinal, who had turned against the French. In 1510 Schiner arranged for Swiss support of the Holy League formed by Pope Julius II for the expulsion of the foreigner from Italy. After the Battle of Ravenna in 1512 Swiss, papal, and Venetian forces in cooperation were able to secure the removal of the French from the plains of Lombardy. Massimiliano Sforza, son of Ludovico il Moro, returned as duke of Milan and acquiesced in the occupation of Locarno, Lugano, Mendrisio, and the Val d'Ossola by the Confederates, while the Graubünden secured the Valtellina, Bormio, and Chiavenna. At Novara (1513) a fresh French army was almost annihilated in a hard-fought battle. Another Swiss force penetrated into French Burgundy as far as Dijon

but returned home when promised a substantial sum of money.

Francis I of France launched a new invasion of northern Italy in 1515. The division of interests between the eastern cantons (reluctant to leave the St. Gotthard route uncovered) and Bern (traditionally well disposed to France), together with a growing dislike of mercenary service and an equally strong distrust of Cardinal Schiner, led to a division of forces. Bern, Fribourg, Solothurn, and the Valais were bought off by the French in the Treaty of Gallarate; and a truncated Swiss army, with Milanese and papal support, was defeated on Sept. 14, 1515, at Marignano (*q.v.*) with heavy losses. Francis I agreed to easy terms in 1516, acknowledging all that the Confederates and the Graubünden had gained in the Bellinzona area except Domodossola and paying a considerable sum as well, while the Swiss promised not to serve in wars against the French king. This settlement is known as the Perpetual Peace.

**14. The Reformation: Zürich and Geneva.**—Five dioceses—Basel, Lausanne, Sion, Chur, and Constance—provided the framework for the ministrations of the Catholic Church to the Swiss people. Neither the institutions nor the men were suited to the changing needs of the 16th century. The bishops were sometimes nonresident, sometimes incompetent, often, as absentee landlords, disliked. The parish priests were frequently ignorant and sometimes lazy or immoral. While there were no territorial princes, as in Germany, to benefit by a redistribution of church property, the considerable monastic lands were coveted by certain cities. The humanism of the Renaissance (*q.v.*) could hardly impinge upon the lives and thoughts of peasant mountain dwellers but contacts with Italy were easy and Basel became the home of Erasmus and Johann Froben's printing press.

All these things affected the career of Huldreich Zwingli (*q.v.*; 1484–1531), who became the most influential figure in the Swiss Reformation. A musical, intelligent boy of good peasant stock from the Toggenburg district, he had taught classics at the University of Basel and had been parish priest at Glarus (1506) and at Einsiedeln (1516) before becoming people's priest (*Leutpriest*) in the Zürich minster in 1518. He had, moreover, been to Rome and with Swiss armies in the field, had studied widely in the Fathers, and read the Bible in the original Hebrew and Greek. Experience had convinced him that mercenary service was harmful to his countrymen, and his Bible study and reading of the works of Erasmus

had made him critical of the pope and opposed to indulgences.

In the all-important city of Zürich the pulpit, properly used, could be most influential, and on Jan. 2, 1519, Zwingli started a course of sermons on St. Matthew's Gospel such as had not been heard in the minster before: his teaching was inevitably called Lutheran although it was, in fact, the independent outcome of his own thought and studies. In the same year there was plague in Zürich, which caused a revivalist movement. Next, in 1520, Zwingli was denouncing the compulsory payment of tithe to the canons. The city council then permitted the public preaching of the "true divine Scriptures," and in 1522 Zwingli formally challenged ecclesiastical authority by eating meat (sausage) during Lent and by denouncing clerical celibacy. He set out his convictions and theological standpoint in 67 conclusions, which were publicly debated in Zürich in 1523. Appealing to the Bible, he convinced his hearers: the Great Minster was reformed, monks and nuns began to leave the cloister, the clergy to marry (Zwingli himself was publicly married in 1524), and the communion to be administered in both kinds, the income from church property being diverted to education or poor relief. Images were discounted, preaching encouraged, relics hidden or destroyed, monasteries dissolved, and finally, in April 1525, the Mass was superseded by a simple commemorative service. Zürich had thus by steady stages accepted the Reformation, and Zwingli was left almost as head of the state as well as religious leader. He published his doctrines in print, issued a vernacular translation of the Bible, rejected the teaching of the Anabaptists (who were proscribed), and secured a permanent majority of supporters in the city council.

The Catholic cantons made every effort to isolate the new teaching in Zürich and to prevent its extension even to the common lordships over which Zürich shared jurisdiction. It soon became apparent that religious and economic interests were likely to coincide: the strongly Catholic cantons were, generally, the rural mountainous areas, Uri, Schwyz, Zug, Unterwalden, Lucerne, Solothurn, and Fribourg, while the city-dominated communities, Basel, Bern, and Schaffhausen in particular, were lost to the old faith.

The coherence of the Confederation had been difficult to maintain in 1480: it proved almost impossible in 1529. Early in that year Lucerne, Uri, Schwyz, Unterwalden, and Zug, encouraged by Pope Clement VII and by the emperor Charles V, formed a separatist group known as the Christian Union; Zürich then tried to force the pace by an armed campaign in June, but the western states, particularly Bern, were not interested, and the antagonists were singularly loath to kill one another. The first armistice at Kappel (June 24) was followed by an agreement to dissolve the Christian Union, to allow freedom of worship in the common lordships, and to decline further foreign pensions. But neither side kept the spirit of the agreement. Then, in October, the efforts of Philip (q.v.) of Hesse to unite the Protestants by bringing Luther and Zwingli together at Marburg conspicuously failed.

By 1531, when an Italian adventurer attacked the Protestant Graubünden, the Forest cantons could refuse to come to the help of a non-Catholic state. They could also complain that the Evangelical faith was being forced on the Thurgau. Choosing time and place with great skill, the five Catholic cantons which had belonged to the Christian Union declared war on Zürich at Lucerne on Oct. 4, 1531, and sent a force north to Kappel, where they met a hurriedly raised detachment of volunteers from Zürich led by Jörg Göltdli and with Zwingli in person among them. The Battle of Kappel (Oct. 11, 1531) resulted in a Catholic victory and in Zwingli's death.

Zürich thus lost the effective leadership of the Confederation, which devolved, not very satisfactorily, upon Bern; the Catholics regained an appreciable amount of ground, so that when the Jesuits came they were in a strong position. For almost three centuries after 1531 religion so divided the Swiss people that cooperation was hardly possible. The rare diets of the whole Confederation, necessary only for the administration of commonly owned territories, were brief and formal; the Protestant cities entered into cordial relations with England, Scotland, northern Germany, and Scandinavia; the Catholic states were the willing agents of France, Spain, and Austria on the rare occasions when these powers were

found acting together. The wonder is that the Confederation survived at all.

Geneva (q.v.), which, it should be remembered, was not a member of the Confederation till 1815, occupied a strategically important position southwest of Vaud on the frontiers of lands more securely held by the House of Savoy. It had entered into a pact of co-citizenship with Bern and Fribourg in 1526 in order to throw off the rule of its bishop and to prevent its absorption by Savoy. The Protestant faith was brought into Vaud from France and preached by Guillaume Farel and Pierre Viret under the protection of Bern, which had already taken various parts of Vaud into a kind of protective custody. The Reformers were successful in 1535, after the usual public disputation, in inducing the independent city council of Geneva to forbid the public celebration of the Mass. Threatened by their former bishop and by Savoy, the Genevans appealed to Bern, and a Bernese force under Hans Franz Nægeli overran Vaud, occupied Lausanne, and brought temporary security to Geneva. At this juncture John Calvin (q.v.), who in 1536 had published at Basel his definitive *Christianae Religionis Institutio*, came to Geneva and, not without some setbacks, soon made that city the centre of an active and independent religious teaching. Calvinist doctrine was explicit and logical, the duties of the Christian household were clearly prescribed, attendance at church, particularly at sermons, was enforced, sumptuary laws were enacted by the city, an excellent system of schools was established, and ministers of religion were chosen with the greatest care for their character and capacity. By the Agreement of Zürich (*Consensus Tigurinus*), made with Heinrich Bullinger in 1549, Calvinism was free to infiltrate the whole of Protestant Switzerland.

The Catholic cantons would not agree to the inclusion of Geneva in the Confederation. Geneva therefore had to rely upon the alliance with Bern, upon the desire of the communities of the Valais that Savoyard aggression should be restrained, and upon the obvious interest of France in a friendly neutral at such a strategically important point. Savoy's attempt to capture Geneva by surprise in 1602 was a failure.

**15. The Counter-Reformation, the Valtellina, and the Thirty Years' War.**—The decrees of the Council of Trent (q.v.) inaugurated the Catholic Counter-Reformation. Their acceptance in Glarus, with the ultimate elimination of Zwinglianism there, was enforced to a large extent by well-managed campaigns collectively called the Tschudi War (1558–64) after their chief promoter the historian Gilg Tschudi (q.v.). From 1565 the work of reconverting the Swiss Protestants to Catholicism was actively sponsored by St. Charles Borromeo (q.v.), whose archdiocese of Milan included much of southern Switzerland. While he was ready to strain law and treaties in his zeal to stamp out the new beliefs, he set a personal example of piety, visited Einsiedeln, and founded the Collegio Elvetico, or Swiss College, in Milan, whence missionaries came north. The Jesuits also came and founded colleges of their own at Lucerne and at Fribourg; but the Inquisition found little support even in the Catholic cantons, and the Protestants who were expelled from Locarno took refuge in Zürich.

Lucerne, which was made the seat of a permanent papal nunciature in 1579, became the virtual capital of Catholic Switzerland. Its chief magistrate, Ludwig Pfyffer (d. 1594), who had served with Swiss mercenaries in France in the 1560s, conformed his policy to that of the French Holy League in the later Wars of Religion and made Lucerne the chief component of the Golden League (1586), which supported Philip II of Spain. Melchior Lussy (d. 1606) not only advanced the Golden League's cause by diplomacy, enriching himself in the process, but also won the pope's confidence and averted the threatened dissolution of the Confederation. Meanwhile Appenzell between 1579 and 1594 was subjected to a process of reconversion so intensive that the canton split into two zones, Äusser-Rhoden (Protestant) and Inner-Rhoden (Catholic).

The loosely united Graubünden and neighbouring leagues, two-thirds Reformed, one-third Catholic, controlled the important eastern passes, which were of interest alike to Milan and to Venice. Milan was under Spanish Habsburg control and jealous of its ancient commercial and territorial rival Venice, which in 1603 secured the friendship of the Graubünden. The Valtellina (q.v.)

was governed by the Graubünden and inhabited by Catholics; its roads formed the most convenient link between Milan and Austria, whose cooperation with one another was dangerous to France. A revolt in the Valtellina in 1620 led to Spanish support for the inhabitants against their northern masters and to successful Austrian intervention. France then took an interest in the affair; the Treaty of Monzón (1626) called in the pope as a third party; and further disputes, which led to further French intervention, were fomented by the local patriot Georg Jenatsch (*q.v.*), a pastor who eventually turned Catholic. By the settlement of 1639, the sovereignty of the Graubünden over the Valtellina was affirmed, with the rights of the Catholics there specially protected.

Meanwhile the revolt of Bohemia against the Austrian Habsburgs (1618) had inaugurated a conflict which grew to involve every great power of Europe: the Thirty Years' War (*q.v.*). All Switzerland was interested in the conflict, of which, indeed the affair of the Valtellina may be regarded as an aspect; but the religious division in the Confederation effectually prevented any corporate action. This was advantageous, for a Habsburg victory might have meant a renewal of Habsburg claims or an enforcement of the Edict of Restitution (whereby the Catholics recovered lost ecclesiastical lands), while a decisive Swedish triumph must have altered the balance of power in the Confederation decisively. Many Swiss soldiers were hired by either side, and much material was sold to the combatants at a profit, while the necessities of frontier defense caused all the 13 states to come to a rare agreement in the *Defensionale* of Wil (1647). The frontiers would be defended against any aggressor and a mixed council of war of Protestant and Catholics would direct a force recruited from all parts of the Confederation and its subjects and allies. The *Defensionale* was to be revised in 1668 and certain details were challenged later, but the acceptance of the principle of defense of neutrality was significant.

The negotiation of the Peace of Westphalia (1648) owed much to the indefatigable labours of Johann Rudolf Wettstein, burgo-master of Basel. It was appropriate that this European instrument should take notice of the explicit renunciation by the emperor Ferdinand III of all Imperial claims over Basel and the former Habsburg territories in Switzerland, an act followed by the abrogation of any claim by the Imperial Chamber to exercise appellate jurisdiction there.

**16. Economic Development from 1648.**—The soil of Switzerland, however carefully cultivated, could not support its growing population, and the temporary prosperity caused by the wars gave way to a depression in the latter part of the 17th century. Exports were necessary, and for this an industry was required which should use as little heat as possible and make the maximum use of human ingenuity and activity. Home industries were popular, partly because conditions in the valleys restricted outdoor work, particularly in the winter. Hence wood carving, spinning, frame-work knitting, and embroidery were popular; water power made textile manufacture (silk, cotton, and linen) profitable, particularly around the Lake of Zürich and in Sankt Gallen; and in western Switzerland the construction of clocks and watches and of musical instruments, at first luxury trades allied to the art of the goldsmith and the jeweler, centred in Geneva, spread to Neuchâtel, Olten, La Chaux de Fonds, and Le Locle. Basel was a commercial city, where stockings and silk ribbon and the preparation of tobacco and snuff occupied many; Bern remained primarily the capital of a great agricultural state, where the real or imaginary virtues of the peasant received an exaggerated recognition. Mercenary service, particularly with the French Army, was a popular form of employment, and returning soldiers brought news of foreign markets and fashions that was often valuable.

The government of a number of states, Bern, Lucerne, Fribourg, and Solothurn in particular, was in the hands of a patrician aristocracy, exclusive and splendid. Difficult economic conditions after the Thirty Years' War led to a rising in 1653 of the peasants of the Entlebuch against Lucerne. With the help of neighbouring governments it was suppressed, but it was followed by similar trouble in the Bernese Oberland and in the rural territories of Basel. The peasants seemed united, and the cities in alarm co-

operated for the defense of their privileges, irrespective of religious differences. A battle at Herzogenbuchsee established the cities' superiority, and harsh punishments were meted out (followed by some belated reforms).

**17. The First Villmergen War.**—Zürich tried to make the Confederation more of a reality, but the attempt broke on the rock of religious prejudice. The Catholic states reinstituted the Golden League in 1655, and the expulsion of some Protestant families from Arth led to a split between Schwyz and Zürich which developed into civil war: Schwyz, Uri, Unterwalden, Zug, and Lucerne fought against Zürich and Bern. At Villmergen (Jan. 24, 1656) the Catholics under Christopher Pfyffer defeated their opponents and reasserted the favourable position secured at Kappel in 1531 and the complete individual sovereignty of the cantons.

**18. Relations with Louis XIV.**—In the age of Louis XIV the Swiss could hardly escape the all-pervading influence of France. If the Protestant states were not very eager to help the persecutor of the Huguenots, and the Catholic states looked to Spain for help, both could be influenced by the appeal of Jean de la Barde, the French ambassador, to renew the Perpetual Peace with France. In 1663 an embassy confirmed this renewal by a spectacular public oath in Notre Dame at Paris and for the next half century French influence was paramount in such external relations as the Confederation had.

Louis XIV's aggressive policy was in many respects at the expense of ancient Swiss interests. At the end of the 15th century Swiss influence had been almost paramount in the Franche-Comté and in Alsace, and these were exactly the areas against which Louis proceeded most successfully (*see DUTCH WARS: The Franco-Spanish War of Devolution and The War of 1672-78; FRANCE: History*). In 1668 the Habsburgs succeeded in recovering possession of the Franche-Comté, but the French threat to it alarmed the Confederates. Its final annexation to France in 1678 brought France to the Bernese frontier and caused fears for the future of French-speaking Vaud, and the French occupation of Strasbourg (1681) meant that Mulhouse and Rottweil could not hope to remain permanently linked with the Confederation. Basel, too, recognized how serious French pressure could be when a French battery at Hüningen confronted its defenses.

The Confederation remained discreetly neutral during the War of the Spanish Succession (*q.v.*), but politically its independence was the safer because of the outcome of that war, which checked French ambitions. During the war a particular setback to France occurred in Neuchâtel: on the extinction of the ruling family of Orléans-Longueville in 1707, a struggle ensued between the French candidate François Louis de Bourbon, prince of Conti, and the Prussian king Frederick I, in which the latter won the principality for the Hohenzollerns.

**19. The Second Villmergen War.**—The religious question in the common lordships, particularly the Thurgau and the Rheintal was a delicate one, as the populations of both creeds were ruled by nominally cooperating states of similarly divergent faiths. Questions of mixed marriages and the education of children were urgent ones and roused strong feelings, which were accentuated by the attempt of the prince-abbot of Sankt Gallen to dictate to his mainly Protestant subjects in the Toggenburg district. A road entirely under Catholic control was being constructed from Schwyz into Imperial territory, and Abbot Leodegar Burgisser was determined that the Toggenburgers should contribute labour and materials to its construction. They demurred and appealed successfully for support to Bern and to Zürich, and in 1712 an armed conflict broke out. The abbot had the support of the emperor Charles VI which made France willing to mediate. Bern and Zürich cooperated well, while Lucerne was unable to coordinate effectively the forces of the Forest cantons. The abbot fled, the Protestants won a victory at Bremgarten, besieged Baden, and blockaded their enemies elsewhere. A final battle (July 25, 1712) at Villmergen settled the issue in their favour; and the Peace of Aarau (Aug. 1, 1712) established real equality of treatment for both sides in the common lordships, increased decisively the influence of Bern and Zürich in the Confederation, and entirely superseded the second Peace of Kappel.

**20. Domestic Affairs and Intellectual Life in the 18th Century.**—Every form of government existed side by side: a patrician aristocracy, proud, exclusive, and competent, ruled in Bern, Fribourg, Lucerne, and Solothurn; Zürich, Basel, and Schaffhausen were governed by their craft guilds and trading corporations; in the oldest states, Zug, Uri, Unterwalden, Schwyz, Glarus, and Appenzell, the primitive democracy of the *Landsgemeinde* assured the participation in the government of every adult male citizen; in Neuchâtel and Sankt Gallen autocratic princes were in power. Every state, individually or collectively, ruled subject territories; there was little sense of nationality and no common language, coinage, system of weights and measures, army, or law-courts. There was a general air of contentment, prosperity, and industry.

A vigorous and varied intellectual life was evidenced by the work of Johann Jakob Bodmer, Johann Caspar Lavater, the Bernoulli family at Basel, Albrecht von Haller, and Johann Heinrich Pestalozzi (*qq.v.*), as well as the philosopher Isaac Iselin (1728–82). The country was increasingly visited by foreigners: Edward Gibbon wrote much of his *History of the Decline and Fall of the Roman Empire* in Lausanne; Voltaire was to be found on the frontier at Ferney. Jean Jacques Rousseau was proud to describe himself as a citizen of Geneva, and his thought was profoundly influenced by Swiss conditions.

The ideas of the Enlightenment (*q.v.*), rationalism, and general improvement which became widespread in 18th-century Europe were eagerly absorbed in Switzerland. The writings of Montesquieu, Voltaire, Diderot, D'Alembert, and the Encyclopaedists, as well as the almost homebred solvent thought of Rousseau, powerfully influenced the intellectual circles; many talked of liberty and equality in societies in which there was little practical application of either.

The general complacency was disturbed by several manifestations of discontent. Jean Daniel Davel attempted to free Lausanne and part of Vaud from the domination of Bern in 1723; he was unsuccessful and was executed. There was trouble in Appenzell raised by Lorenz Zellweger in 1733. Geneva unwillingly acquiesced in a greater degree of democratic government in 1738. A serious conspiracy against Bern headed by Samuel Henzi was suppressed in 1749. There were demonstrations against the authority of Uri in the Val Leventina in 1755 and armed opposition to the patricians of Fribourg in 1781; but neither these, nor somewhat similar explosions in Schwyz, Lucerne, and Geneva, presented any real challenge to constituted authority. A consciousness that something more than mere defense and self-interest held the Swiss states together was growing, and this found public expression in the formation of the Helvetic Society (*Helvetische Gesellschaft*) in 1761.

**21. The French Revolution and Napoleon.**—Some of the more advanced Swiss thinkers had found life more congenial in France than at home when the French Revolution started in 1789. In 1790 a "Club of Swiss Patriots" was founded in Paris by Jean Castellaz and supported by a number of Vaudois refugees, by Henri Monod, by Jean Jacques Cart, and, most notably, by Frédéric César de La Harpe (1754–1838), who from his post in St. Petersburg as tutor to the future Russian emperor Alexander I urged the French people to support the malcontents in Vaud and the Valais (his cousin Amédée Emmanuel de La Harpe was serving with the Revolutionary Army).

The conservatives in Switzerland were in strong opposition to French Jacobinism; yet when the War of the First Coalition against France broke out in 1792 (*see FRENCH REVOLUTIONARY WARS*) neither the French invasion of the lands of the bishop of Basel in April nor the massacre of Louis XVI's Swiss Guard in the Tuileries Palace on Aug. 10 provoked the Confederation into hostilities. The war party in Switzerland, led by Nikolaus von Steiger, was able to secure only an agreement that the Coalition might recruit Swiss mercenaries. There was, however, a good deal of anti-French activity in Switzerland.

The successful invasion of Italy by Napoleon Bonaparte (1796) and the Peace of Campo Formio (1797) were soon followed by the annexation to the French-sponsored Cisalpine Republic in northern Italy of the three provinces ruled by the Graubünden, namely

the Valtellina, Chiavenna, and Bormio; and the Swiss could do nothing but accept the accomplished fact. In Paris, La Harpe and Peter Ochs (1752–1821) of Basel were urging a French invasion of Switzerland in the name of liberty, using the separatist movement in Vaud as an excuse of intervention. There were inspired riots in the Liestal near Basel and elsewhere, culminating in the proclamation of a "Lemanic Republic" in January 1798. The French Directory at once sent soldiers to the help of the insurgents: Bern resisted, but received no help from the Diet of the Confederation, which debated fruitlessly at Aarau. A French contingent was driven back at Neuenegg (March 5); but at the same time the main Bernese force capitulated at Grauholz, and the city of Bern was occupied. Great quantities of supplies and bullion were carried off to France by Bonaparte's agent Guillaume Brune.

Peter Ochs drafted a new constitution for a unitary Helvetic Republic. The cantons, whose number was increased to 23 by the emancipation of the subject and associated districts, were practically reduced to the status of prefectures; a bicameral legislature (Great Council and Senate), chosen indirectly by manhood suffrage, was to be responsible for lawmaking; and a Directory of five members was constituted the executive. The rights of the individual citizen were written into the constitution, including freedom of worship, of meeting, of petition, and of the press. A national militia was embodied, and local government was controlled by centrally appointed prefects. Geneva was annexed to France.

The new constitution was not imposed without resistance. In Nidwalden a revolt was savagely put down by Gen. Balthasar de Schauenbourg, but discontent continued to manifest itself in the east, especially when the country was marched over by opposing armies in the War of the Second Coalition. A compulsory alliance with France gave that country the right to use Swiss roads for military purposes, and the French guarantee of the Helvetic Republic offered easy opportunities for intervention. The Coalition regarded the Republic as a satellite of France, and in May 1799 Austrian and Russian forces under A. V. Suvorov met a French army under André Masséna near Zürich before making a classic retirement into the Vorarlberg. The campaign had devastated the countryside; the price of provisions rose alarmingly; and a bad harvest made the winter of 1800 one that was long to be remembered for misery and unemployment.

The cost of the new centralized government was relatively high, although the burden was more equally distributed, direct taxation being introduced for the first time and feudal dues, *corvées*, tithes, and ground rents abolished without compensation. Some money was spent on education, and an elaborate scheme of free or cheap public instruction (culminating in a national university as in France) was adumbrated, but little could be done in a short time. Pestalozzi, however, was given a free hand to proceed with his innovations, which attracted much notice, although his adventures in journalism, as editor of the *Helvetisches Volksblatt*, were less satisfactory.

The first constitution barely outlived the Directory in France. Then, after violent struggles between the protagonists of greater centralization and those who stood for more cantonal authority, the short-lived constitution of Malmaison was established in May 1801. Aloys Reding was chosen as *Landammann* or head of the state. He had to meet political and financial difficulties, culminating in a rebellion in Vaud and a kind of counterrevolutionary movement in the Aargau and in Bern. Napoleon promptly intervened to dictate the Act of Mediation from Saint-Cloud (Sept. 30, 1802; amplified on Feb. 19, 1803). This substituted a new Swiss Confederation for the Helvetic Republic. The cantons were again defined, with boundaries substantially as they have remained ever since. There resulted 19 cantons, namely the 13 of the pre-Revolutionary Confederation together with an enlarged Aargau, an enlarged Vaud (these two were created at Bern's expense), the Thurgau, an enlarged Sankt Gallen, Graubünden, and Ticino (*q.v.*). In the new cantons the representative democratic institutions were accepted; in the old *Landsgemeinde* cantons popular open-air voting continued but was limited to men of 20 years or more; and in the city cantons (Zürich, Bern, Fribourg, Solothurn, Basel, and Schaffhausen) the old aristocracy regained some of its

ancient influence under new forms. With Lucerne substituted for Schaffhausen, these latter became the directing cantons, having seniority in turn, the chief magistrate for the year having custody of the seal of the Republic and presiding over the assembly. The sovereign rights of the cantons, the issue of money, and control over customs, education, monasteries, and the posts were restored, but freedom before the law, of settlement, and of occupation was guaranteed to all citizens.

Napoleon was a relatively popular protector until war with Great Britain (see NAPOLEONIC WARS) obliged him to demand the 16,000 men promised him by the military convention which he had imposed on the new Confederation. British recruiting of mercenaries was stopped, and Switzerland was forced to participate in the Continental System, with great harm to its own commerce and industry, particularly in cotton. The Valais, which had been con-

stituted as a separate republic outside the Swiss Confederation in 1802, was united with France as the *département* of the Simplon in 1810, nominally to put an end to anarchy; Ticino was occupied by French-commanded Italian troops to stop smuggling; and Neuchâtel was handed over to Marshal P. A. Berthier as a kind of feudal fief. Thousands of Swiss soldiers took part in Napoleon's invasion of Russia (1812); they fought well in the Battle of the Berezina during the retreat, but lost most of their effectives.

After the Battle of Leipzig (1813), when Napoleon's power was crumbling, the *Landammann* for the year, Hans Reinhard, called a special assembly at Zürich, which voted for armed neutrality. Metternich, the Austrian foreign minister, soon saw this policy to be on the whole to the advantage of France and therefore encouraged certain elements, who desired a restoration of pre-Revolutionary conditions, to apply for military help. An allied force marched through northern Switzerland on its way into France at the beginning of 1814, while the Napoleonic Act of Mediation was formally denounced.

**22. The Restoration.**—The Congress of Vienna (*q.v.*) devoted comparatively little time to the Swiss question, but certain of its decisions were nonetheless of far-reaching importance. It made as few boundary alterations as possible. Châvenna, Bormio, and the Valtellina were annexed to Austria's new Kingdom of Lombardy-Venetia; but on the other hand, partly as a result of the efforts of Charles Pictet de Rochement, Geneva was at last united to the Confederation with reasonable boundaries, as too was the Valais. Neuchâtel, over which the suzerainty of the king of Prussia was restored, was also admitted to the

Confederation, and the independent existence of Vaud as a separate canton was accepted. Bern received the city of Biel and the former prince-bishopric of Basel. The whole Swiss state was declared neutral. The northern part of Savoy, belonging to Sardinia-Piedmont, was also neutralized.

The return of Napoleon to France for the Hundred Days in 1815 made no substantial difference: Swiss soldiers in the French service did not join him, and a Swiss contingent marched with the allies, who were allowed to cross Swiss territory, into France. A small modification of the frontier of Vaud and the creation of a customs-free zone in Gex and its neighbourhood were secured under the second Treaty of Paris (Nov. 20, 1815); and adjustments with Savoy followed under the Treaty of Turin (March 16, 1816).

The Swiss Confederation now consisted of 22 contiguous cantons. Its constitution, after a conservative patrician restoration

in Bern and some rioting elsewhere, had been decided at the "Long Diet" of Zürich (April–September 1814), which produced the Federal Pact ratified in August 1815. Its keynote was the full restoration of the sovereignty of the cantons, almost the only federal institution being the Army, for the upkeep of which a special fund was voted. Each canton was equally represented in the Diet, Lucerne, Zürich, and Bern acting as chief city for two years in turn. The possessions of the monasteries were placed under federal protection, but the earlier general freedom of worship, as likewise that of settlement, was not retained. Each canton continued to collect its own customs, coin its own money, and manage its own affairs by the customary machinery. The franchise was everywhere limited so as to favour the old ruling families and the property owners, and any alteration of the federal *status quo* was made constitutionally impossible.

Military service with foreign powers again became possible: Louis XVIII of France gladly enlisted a number of Swiss. Reserving its neutrality, the Confederation declared its adhesion to the Holy Alliance in 1817, thereby pleasing the Russian emperor Alexander I; but political refugees in some numbers obtained asylum within its borders, so that Metternich complained that the country was a focus of revolutionary plots and in a state of anarchy. The Diet even agreed to place limitations on the freedom of the press and on the reception of aliens. Economically the country suffered from the rigid tariff restrictions of its neighbours (France and Austria in particular), from the decline in European purchasing power after the Napoleonic Wars, from successful British competition in world textile markets, and from its own constitutional inability to have any common policy on imports. Apart from some slight manifestations of embryonic nationalism and some rather more substantial signs of a religious revival, the Swiss states showed little activity in the 1820s.

News of the July Revolution in Paris in 1830 caused a good deal of excitement among the politically minded young men of certain Swiss cities. Clubs, societies, even athletic associations began to demand larger measures of cantonal democracy, more popular education, and some protection of women and children against industrial exploitation. A number of mass demonstrations led to the introduction of more liberal legislation in 11 of the larger cantons in 1831, implying acceptance of the principle of popular sovereignty and the expansion of the franchise. More schools and training colleges for teachers were opened and universities were founded at Zürich and Bern. There were, however, exceptions, and the surge forward was followed by a reaction. In Schwyz the opposition of reformers and conservatives was so violent that only the intervention of federal troops saved the state from civil war or self-partition. In Basel long-standing differences between the relatively wealthy city, with great external interests, and the predominantly agricultural countryside came to a head in 1831. The adoption of a democratic constitution for the state would give political preponderance to the country people, and this the citizens were determined to resist. After violent demonstrations in 1831 the canton was divided in 1833 into two halves, Basel-Stadt and Basel-Land, which have remained permanent.

Frederick William III of Prussia in 1831 most reluctantly abandoned a small part of his absolute rights in his principality of Neuchâtel (e.g., that of nominating the whole of the cantonal council); but neither the republicans nor the monarchists there were long satisfied with the compromise, and clashes between them continued. One result of these differences was the formation in 1832 of the Siebnerkonkordat or Agreement of Seven (Zürich, Bern, Lucerne, Solothurn, Sankt Gallen, Aargau, and Thurgau), opposed by the conservatives united in the Sarnenbund or League of Sarnen (Basel-Stadt, Uri, Unterwalden, Schwyz, and Neuchâtel). None of these internal changes affected the traditional willingness of the country to shelter political refugees: Poles were welcomed in considerable numbers in the north, while the harbouring of Prince Louis Napoleon (particularly after his attempted coup at Strasbourg; see NAPOLEON III) and the notorious use of Swiss bases by the Italian revolutionary Giuseppe Mazzini almost brought about war.

23. The Sonderbund War.—The 1830s were years of consid-

erable literary activity and of much thought about the future of the Confederation. Strictly constitutional revision was difficult, if not impossible, but the changing needs of the times and the general modification of opinion toward more liberal forms of government clearly suggested change. With a growth of national feeling went a growing conviction that there were certain minimum individual rights of the citizens that ought to be secured to all, and some were prepared to enforce this point of view; others were impressed by the expense and dislocation caused by each canton's having its own tariff and customs barriers. There were several local manifestations of discontent, but they remained localized and ineffective.

The bond which made concerted action feasible was found in religion. How was the principle of religious freedom to be enforced? The Articles of Baden (1834), condemned by Pope Gregory XVI but upheld by the liberal cantons, called for a general diminution of ecclesiastical privileges and exclusive claims. A mass demonstration against the appointment of the radically unorthodox D. F. Strauss to a chair of theology at Zürich in 1839 indicated the depth of passion aroused. Matters came to a head in Aargau. There in 1835 the monks of Muri had objected to taking an oath of loyalty, and in 1840 the Catholic minority demonstrated in arms against a liberal revision of the constitution. The cantonal government in 1841 dissolved the Aargau monasteries, which were held to have fomented the revolt. The Federal Pact of 1815, however, had expressly guaranteed the property of the monasteries against secularization, and the Aargau Catholics appealed to their friends in the south.

Lucerne, Uri, Schwyz, Unterwalden, Zug, and Fribourg, at a conference on Sept. 13, 1843, proposed to split themselves off from the cantons "disloyal" to the Federal Pact; and this alignment, to which Valais adhered in 1844, was to be the origin of the Sonderbund of 1845. The chief Catholic canton was Lucerne, and there Joseph Leu in 1844 secured the recall of the Jesuits, invited by Eutych Kopp, to undertake the teaching of theology and the control of the clerical seminary. This action was lawfully done and lay within the proper province of the canton, but was highly provocative. A demonstration against it in Lucerne itself was severely punished, and a general popular demand for the expulsion of the Jesuits from the Confederation was ignored. The radicals passed from argument to violence, and from most of the Protestant cantons bands of volunteers (*Freischärler*) marched on Lucerne under the command of Ulrich Ochsenbein, a Bernese staff officer. The expedition was mismanaged, and in a fight at Malters more than 100 men were killed and more than 1,800 made prisoner (April 1, 1845). On July 20, Joseph Leu was assassinated.

On Dec. 11, 1845, the Catholic cantons, Lucerne, Uri, Schwyz, Zug, Unterwalden, Fribourg, and Valais, formed themselves into a separatist confederation, the Sonderbund. The primary purpose was to prevent any alteration of the Federal Pact of 1815, even if this were the declared will of the majority of the people, and foreign alliances were welcomed to this end. Through 1846 opposition grew. Bern, Solothurn, Zürich, Vaud, and finally Geneva (under James Fazy) elected radical governments, determined to declare the Sonderbund an unlawful pact. In May 1847 Sankt Gallen joined the liberal cantons, and 12 votes out of 22 were certain. The Diet met in Bern in July 1847 under the presidency of Ochsenbein and by a majority declared the Sonderbund to be dissolved. A commission was appointed to draft a new Federal Pact, and the expulsion of the Jesuits from Lucerne, Fribourg, Schwyz, and Valais was ordered, together with their exclusion from the whole Confederation.

In the name of religion and of state rights the Sonderbund determined to resist by force. Its leader, Constantin Siegwart-Müller, purchased arms, collected an army under the command of Johann Ulrich von Salis-Soglio, and looked for support from France and Austria; but this support was slow in coming, partly because the British foreign secretary, Lord Palmerston, openly sympathized with the opposite side. The Sonderbund War was soon over. While at Lucerne there were divided counsels and uncertainty of purpose, the radical cantons entrusted their men and fortunes unreservedly to Guillaume Henri Dufour of Geneva, a somewhat conservative professional soldier, simple, upright, and unselfish. Du-

four had more men than his opponents, and these better trained and equipped, with better guns and superior economic advantages. All these he used to decisive effect. Fribourg capitulated on Nov. 14, 1847, almost without fighting, and the ring closed relentlessly in on Lucerne. Zug surrendered on Nov. 21, and two days later the decisive battles were fought at Meierskappel and Gislikon. Lucerne was entered, officers, Jesuits, and nuns fleeing by steamer to Flüelen and then over the St. Gotthard to exile. Valais was the last canton to submit, on Nov. 28. Somewhat more than 100 men on both sides had been killed.

The costs of the war were charged to the losers, and Appenzell Inner-Rhoden and Neuchâtel had to pay fines for their neutrality. A collective note from the European powers, unsupported by Palmerston (who sent Stratford Canning with sympathetic instructions to Bern), could be and was ignored until the greater troubles of those powers in the revolutionary year 1848 left Switzerland free to work out its own destiny.

**24. The Federal Constitution of 1848.**—The revision commission had a new constitution ready for submission to the cantons in June 1848, and it was adopted with little change by 15½ cantons (1,897,887 votes) against 6½ (293,371 votes). The central authority was strengthened, particularly in regard to defense, law and order, and the promotion of the common welfare. There was to be a cabinet or Federal Council (*Bundesrat*) of seven, a supreme Federal Court (*Bundesgericht*), a Senate or Council of States (*Ständerat*) consisting of two representatives from each canton, and a National Council (*Nationalrat*) representing the country as a whole. Foreign affairs became the concern of the Federation only, although separate cantons might, with federal approval, make agreements not of a political nature with one another and with neighbouring countries. The posts, currency, weights and measures, and customs duties became the province of the Federation, which thus acquired an independent revenue, cantonal expenses being met by local levies, taxes on salt, an excise on wine, and stamp duties. Universal military service in a federal force was accepted; very small cantonal armies were approved, and the cantons controlled infantry training but not the cavalry or artillery. Service with foreign armies, military capitulations, and the acceptance of foreign pensions or decorations were prohibited. Freedom of the press, of worship, of association, and of settlement and equality before the law were secured to all, but these were somewhat narrowly interpreted in some cantons—the Jews remained under special disabilities and the Jesuits were excluded.

Bern became the seat of the government, Lausanne of the high court, and Zürich of the Federal Institute of Technology. It had been the hope of many that a great federal university at Zürich would unite the higher education of the country, the ordinary teaching of children being left to the cantons; but the existing academies at Geneva, Lausanne, and Neuchâtel and the universities of Bern and Basel were not prepared to accept this measure of academic unification, and in the end only technology was thus centralized. Similarly it was only after considerable differences of opinion that the French franc and the metric system of weights and measures were fully adopted.

**25. The Neuchâtel Crisis (1856–57).**—Neuchâtel, notwithstanding the rights of Frederick William IV of Prussia, had in 1848 adopted a republican form of constitution, which had been accepted as that of a federal canton. This was partly the work of the industrial region of Le Locle and La Chaux-de-Fonds and was resisted by the older ruling families, who proclaimed their loyalty to Frederick William. The last of several attempts at counterrevolution took place in September 1856, when the loyalists under Comte Frédéric de Pourtales-Steiger gained possession of the castle of Neuchâtel and had to be ejected by force. Frederick William threatened to intervene on behalf of his "subjects" and mobilized his men; the Federal Army was placed on a war footing and sent to the northern frontier. British good offices and diplomatic pressure on Prussia by Lord Palmerston were followed by the mediation of Napoleon III, and in May 1857 the king gave way, renounced all sovereign rights, and secured an amnesty for his supporters.

**26. The Italian Question and Savoy (1859–60).**—Switzerland, like Great Britain, was a home for political exiles from many countries, in particular for Italian nationalists (see *ITALY: History*). In 1850 some measures were taken to prevent Switzerland from becoming too obvious a base for revolutionary propaganda, but the law on this subject was never very strictly enforced. In Ticino the sympathy of the population for Italian nationalism, combined with provocative anticlerical actions, led to Austrian reprisals in the form of the expulsion of Ticinese from Lombardy and of an economic boycott which caused much suffering. Perhaps only Austrian preoccupation elsewhere prevented matters from being pushed to extremities. When Sardinia-Piedmont, backed by France, began war against the Austrians in Lombardy in 1859 (see *ITALIAN INDEPENDENCE, WARS OF*), federal troops prevented Swiss sympathizers from crossing the frontier to join the Piedmontese and secured the internment of belligerents who fled north.

The war of 1859 was followed in 1860 by the cession of Savoy by Sardinia-Piedmont to France and the reopening of the question of the neutral zone of Chablais, Faucigny, and the Genevois. A federal councillor, Jacob Stämpfli, threatened to readjust matters by a Swiss occupation of this area—a threat impossible to carry into effect, as the easy repulse of a Genevan force that attacked Thonon in March 1860 clearly showed. In the end the neutral zone was enlarged a little, arrangements were made about the collection of customs, and the issue was shelved (until 1919 when full French sovereignty over the area was to be asserted and accepted). The war had further been responsible, indirectly, for the establishment of the International Red Cross Organization, a widely read pamphlet by the Swiss observer Jean Henri Dunant (*q.v.*) having drawn attention to the unnecessary sufferings of the wounded at the Battle of Solferino. In 1864, after much local activity, the Convention of Geneva regulated the care of wounded in war and arranged for the neutralization of the medical and ambulance services, distinguished by the federal cross in reverse colour.

**27. Railway Construction and Industrial Development.**—The Swiss people did not at first welcome the advent of the railway: it was believed to be aesthetically and technically unsuited to mountainous country and it threatened the prosperity of the roadside hotels. The interests of Basel and Zürich conflicted, and cantonal state rights were a serious obstacle. It was therefore not until 1847 that an experimental line was opened between Baden in Aargau and Zürich. After a report from the British engineer Robert Stephenson the Federal Council accepted the necessity for planned railway construction, and a conflict between Alfred Escher on the side of private enterprise and Jacob Stämpfli on that of state ownership and control resulted in the victory of the former. There was soon a mania for railway speculation, and lines were built with little or no coordination, sometimes in conscious rivalry. In 1853 the North Eastern Railway linked Zürich with the Rhine and the Lake of Constance, and in the same year the route Morges–Lausanne–Yverdon was opened; by 1859 the Central Railway joined Basel with Olten and thus to Lucerne on the east and to Solothurn, Bern, and Thun on the south.

Finance, politics, personalities, cantonal rivalries, and strategic considerations soon caused difficulties. The construction of a railway through the St. Gotthard Tunnel was not completed until 1882, after much negotiating with Germany and with Italy. Escher was chairman of the company responsible, the Confederation refusing to accept any financial obligations. The estimates proved inaccurate, and Escher was forced to resign, some part of the excess cost being borne by public funds. There were difficulties about gauge, locomotives, and differential rates, and in 1883 a suggestion of unification by public ownership was rejected by a small majority. A similar suggestion was rejected by a referendum in 1891; but in 1898 nationalization of certain main lines by purchase was accepted by a popular vote, and the principle was extended in 1903 and 1909. Better communications with the outside heightened the flow of the valued tourist traffic.

The existence of ample water power and an industrious population gave Swiss industry a good start, but the absence of coal made further developments difficult until the progress of hydro-

electric schemes supplied an alternative source of heat and energy. Swiss textile manufactures, including cotton goods, largely held their own in a predominantly free-trade world but declined in face of growing protection and large-scale competition. Embroidery of good quality, however, was to maintain a wide market until about 1920, as did the Basel silk-ribbon industry. Dyeing led to a considerable development of the chemical industry; and the traditional localized watchmaking and clockmaking were supplemented by large-scale factory production, which met with considerable success and led to the making of a wide range of machines and locomotives.

The home production of grain decreased in the 1880s, when it became much cheaper to import foreign wheat; the farmers turned to stock breeding and dairy farming. Cheese making, the export of milk products of all kinds, and the chocolate industry became widespread.

## 28. Constitutional Revision and Internal Politics to 1914.

—The German Kulturkampf of the 1870s against the Catholic Church (see GERMANY: History) had its repercussions in Switzerland. The issue of the *Syllabus errorum* by Pope Pius IX in 1864 had attracted a good deal of attention and helped to make the radicals also to some degree anticlerical, and the definition of papal infallibility by the Vatican Council in 1870 and the emergence of the Old Catholics in Germany, with many sympathizers in Switzerland, created difficulties. The Catholics of the diocese of Basel; in particular, refused to follow their bishop, Eugène Lachat, in accepting papal infallibility and declared him deposed. In this they were upheld by the cantonal governments, particularly Bern, but a majority of the clergy stood by their bishop, refused to accept his removal, and protested against the secularization of his property. Bern now required that parish priests should be chosen by their parishioners from among those who were approved by the government and had undergone a state examination. In Geneva the action of the pope in appointing Gaspard Merillod to an apostolic vicariate there without any prior consultations led to Merillod's being expelled from Switzerland (1873), to the recall of the nuncio, and to the prohibition of the activities of religious associations in schools.

The feeling thus aroused helped forward the growing demand for a general revision of the constitution of 1848. The introduction of the "initiative" (i.e., the right of the people to propose legislation) into the canton of Zürich in 1865 was a victory of the left-wing democrats over Escher and his followers. The freedom of the press was extended, the principle of payments to councillors was accepted, and the example of Zürich was largely copied by Bern, Lucerne, and Solothurn. In 1866 the Jews, who had been denied freedom of settlement on commercial grounds, were admitted to full civic rights.

In 1874, partly as a result of the Franco-German War of 1870-71, a revision of the conditions of military service was generally demanded. The division between those demanding greater centralization and increased federal authority and those upholding the rights of the cantons was focused in the rivalry of Emil Welti of Aargau on the former side and Louis Ruchonnet of Vaud on the latter. The centralizing radicals were only partially successful; but a revised federal constitution was accepted by popular vote in April 1874. Direct popular control over the government was at the same time extended by the principle of the referendum, by which a national verdict on an issue could be sought if properly demanded by 30,000 votes or eight cantons. In 1891, moreover, it was agreed that a demand by 50,000 votes (the initiative) could bring similar machinery directly into operation.

Thanks to the reform of 1874, the Army was more directly centralized: discipline and military education, the provision of arms, and the collection of exemption-payments were to be federal matters, the force being based on the cantons (which also promoted some of the officers). Freedom of trade and choice of occupation within any canton was secured to all, and each canton was obliged to make provision for full primary education. Teaching was to be secular, civil marriages were made compulsory, and the foundation of new monasteries was forbidden. Certain other anticlerical regulations were made. The authority and appellate jurisdiction

of the Federal Court at Lausanne was upheld and extended, and federal laws dealing with factories, bank notes, and the railways were made more comprehensive.

The opening of the St. Gotthard route attracted some attention to the Ticino: an increasing number of immigrants heightened party rivalries there, radicals and conservatives being almost precisely equally balanced. Religious feeling made matters worse; the conservatives were accused of manipulating the Ticinese elections so that they would remain permanently in power; and rioting in 1890 ended in the formation of a provisional government of Ticino. Armed federal intervention became necessary, a revised electoral law introduced proportional representation, and an increased electorate was followed by a radical and peaceable administration.

Growing industrialization and an increase in the size of the urban populations were accompanied by the spread of socialism in Switzerland. The Social Democratic Party, formed in 1870, avowedly existed to forward the claims of the manual workers and, under Otto Lang, began to demand social reforms and positive opposition to large-scale capitalist enterprise. A notable piece of practical socialism was the gradual nationalization of the railways.

Political refugees, their numbers increased by German anti-socialist legislation, continued to be a source of difficulty. Anarchists were more difficult to control or eliminate. In 1898 the Austrian empress Elizabeth was assassinated in Geneva; and in 1902, after the murder (1900) of King Humbert of Italy, the Italian government demanded that action should be taken against Giulio Silvestrelli for provocative newspaper articles. A temporary breaking-off of diplomatic relations between Switzerland and Italy followed.

29. World War I.—When World War I broke out in 1914, public attention was soon transferred from the Swiss national exhibition to the needs of defense. The wisdom and the value of the policy of neutrality, imposed alike by public instruments, by national interest, and by tradition, was never in doubt. The citizen-army was rapidly mobilized and sent to guard the frontiers. There was a momentary controversy over the choice of a supreme commander, the parliamentary representatives voting for Theophil Sprecher von Bernegg, the Federal Council (supported by a decisive popular vote) choosing Ulrich Wille. Fortunately a neutral Switzerland had certain advantages both for France and for Germany, and no attack upon its frontiers was ever seriously considered.

Universal military service, the rigours of campaign conditions without an enemy to fight, and the use of soldiers for public works were less resented than the economic conditions imposed on a country which could neither entirely feed itself nor supply all its own raw materials. The tourist traffic, which enthusiasm for mountaineering and allied pursuits had rendered especially active, came to an end; a run on the banks was with difficulty averted; and the large number of resident foreigners added certain difficulties. But it was soon apparent that Swiss services could be of value alike to both belligerent groups and a certain amount of trade became possible. For certain purposes Sète, on the French Mediterranean coast, became an open port for Switzerland. Heavy taxation and a good deal of borrowing were necessary.

The factory workers in the cities were discontented at the rapidly rising prices and at political and industrial conditions unfavourable to them; and the Social Democratic Party became a vehicle for the teaching of Lenin, resident in Zürich until his transference to Russia by the Germans. The constitution, however, made political action slow and ineffective, and in November 1918 a general strike was called. The workers demanded a 48-hr. week, old-age pensions, national health insurance, female suffrage, the election of a new National Council by proportional representation, conscription of labour, and a capital levy. Prompt action by the administration, the hurried expulsion of the Soviet legation, the arrest of strike leaders, and the use of some show of military force ended the general strike quickly, after which a number of the demanded reforms were enacted. Concurrently with the general strike the serious influenza epidemic that affected so much of Europe wrought considerable havoc.

Swiss agencies, governmental and private, including the Red

Cross, were much used by the belligerents, but the expression of Swiss opinion had little effect on the course of the war or on the peace negotiations in Paris. The collapse and partition of the Habsburg Empire decisively altered conditions on the Swiss eastern frontier, where the inhabitants of Vorarlberg (*q.v.*) wished to form themselves into a new canton of the Confederation. The decision about this rested with the Allies, who declined to detach the territory in question from the new Austrian state and ignored the principle of self-determination, so that the Treaty of Saint-Germain left the frontier there unchanged. Switzerland was affected in several ways by the Treaty of Versailles: the international control of shipping on the Rhine thereby became very much a concern of France; the agreement with Germany about the regulation of the St. Gotthard line was revised; and the neutralized "free" zone of Gex and northern Savoy became an undifferentiated part of the French republic.

**30. The League of Nations.**—The Covenant of the League of Nations, in spite of the flattering choice of Geneva as the headquarters of the organization, was not regarded with satisfaction in Switzerland. The guarantees for the maintenance of peace in Europe were less adequate than the Swiss project had suggested, and it was obviously difficult for a permanently neutral state to be associated with the enforcement of collective security and with active resistance to aggression. But Swiss idealism welcomed the general implications of the League, and outstanding difficulties were solved when, by the Declaration of London (Feb. 13, 1920), the Council of the League recognized the special position of Switzerland as permanently neutral and agreed that no military assistance, direct or indirect, could be required from it in the event of a breach of the Covenant, although "economic sanctions" would become applicable. The issue was long debated; the Federal Council advised entry into the League, which was accepted by the National Council by 115 votes to 50, by the Council of States by 30 to 6. The necessary referendum on May 16, 1920, revealed even greater caution: 11½ cantons were for, 10½ against, and the final figures revealed a favourable majority of 90,000 in a total vote of 700,000.

On the social, economic, intellectual, industrial, and medical committees of the League of Nations Swiss help was prominent. The country readily accepted the Kellogg Pact abolishing war as an instrument of policy; and it advocated the early admission of Germany into the League. The passage of foreign armed forces across Switzerland, even on the most direct and manifest League missions, was strenuously and successfully resisted. Relations with the U.S.S.R., embittered by the murder of the Soviet representative V. V. Vorovski at Lausanne in 1923, remained unsatisfactory, and Switzerland opposed the admission of that country into the League in 1934. In 1935 trade relations with Italy were not broken off when Italian forces invaded Ethiopia, although an embargo was placed on the export of arms to both sides. The Chinese-Japanese War, the failure of the Disarmament Conference, the Spanish Civil War, and the successful *Anschluss* between Germany and Austria caused a national reaction, and in May 1938 Switzerland publicly refused to participate in future sanctions.

**31. World War II.**—Switzerland had foreseen the outbreak of a general conflict and was militarily prepared for World War II. On Aug. 30, 1939, Henri Guisan was elected general (commander in chief) by a large majority. The Army was mobilized, the frontiers guarded, and conscription of labour enacted. The tourist traffic and with it the hotel industry, already affected by European conditions, suffered greatly, and both imports and exports were exposed to severe and immediate limitations. With the fall of France in 1940 a large number of French and Polish troops crossed the frontier and were interned. Belligerent aircraft flew high over Swiss territory and were seldom shot down; certain towns, notably Schaffhausen, were accidentally bombed. Defense measures were deliberately concentrated upon the mountainous interior, and these were not put to the test. War materials were supplied to both sides and conveyed by rail between Germany and Italy. A careful censorship was exercised over the press; incitement was avoided, as dislike for German National Socialist activities increased; and the Communist Party was proscribed. Home agriculture, grain-

growing in particular, received all possible encouragement, and the country emerged from the war less impoverished than might have been expected.

**32. Switzerland from 1945.**—Diplomatic relations with the U.S.S.R. were reopened in 1946, but Switzerland remained solidly opposed to Communism. Every effort was made to cooperate with international organizations that was consistent with the maintenance of the increasingly difficult principle of permanent neutrality. Switzerland, therefore, did not join the United Nations, though it became a member of the five UN specialized nonpolitical agencies. It was not a member of the potentially federal European Economic Community, but in 1959 joined the much looser European Free Trade Association. In 1963 Switzerland joined the Council of Europe. Postwar prosperity was high (see *The Economy*, below).

On July 11, 1958, the government issued a statement in favour of arming the country with nuclear weapons. On April 1, 1962 a Socialist-sponsored proposal for a constitutional article prohibiting the manufacture, importation, transit, storage, or use of nuclear weapons in Switzerland was rejected in a national referendum. In 1963, Switzerland adhered to the Nuclear Test-Ban Treaty. By the mid-1960s there was, however, a fairly widespread dislike of the magnitude of the defense budget, representing about 33% of the total annual expenditure (but only 3.5% of the national income). (G. R. P.; X.)

#### IV. POPULATION

Well-organized census returns have been made at ten-year intervals from 1850 onward. The total population according to the 1960 census was 5,429,061, representing a 15% increase since 1950 (an average annual increase of 1.5%). The cantons registering the greatest gains were the industrial ones of Zürich, Zug, Basel, and Genève. The least densely populated cantons were the alpine ones; e.g., Graubünden and Uri. The Jura cantons of Vaud and Neuchâtel were more thickly populated; the densest concentrations were in the cantons of Genève, Basel-Land and Basel-Stadt and Zürich (see Table). Foreigners living in Switzerland (1960)

Area and Population of Switzerland by Cantons

Cantons*	Area in sq. mi.†	Population (1960 census)	Density per sq. mi.	Capital city

\*The local name (German or French) is given first with the year of entrance into the Confederation. Ticino is Italian.

†1 sq. mi. = 2.59 sq. km.

‡Half-canton (Nidwalden and Obwalden were formed from Unterwalden).

numbered 584,739, while 160,774 Swiss citizens were resident abroad. By the mid-1960s the number of foreign workers, largely Italians, exceeded 850,000. This was considered too big a proportion for cultural and political reasons and restrictions on entry and residence were imposed in February 1965. It was evident that Swiss cities were becoming increasingly cosmopolitan. The fol-

owing had populations exceeding 60,000: Zürich, Basel, Geneva, Bern, Lausanne, Winterthur, Sankt Gallen, Lucerne, and Biel. In 1960 the birthrate was 17.6 per 1,000 as compared with a deathrate of 9.7.  
(A. F. A. M.)

## V. ADMINISTRATION AND SOCIAL CONDITIONS

**1. Government.**—The Confederation is composed of 22 cantons (often referred to as 25 federated states because three of them [Unterwalden, Basel, and Appenzell] are subdivided [see Table]). The cantons are built up of communes (more than 3,000) which are usually grouped together to form districts (*Amtsbezirke*).

**Cantons.**—Each of the cantons and half-cantons has its own legislature, executive, and judiciary. Obwalden, Nidwalden, Glarus, Appenzell Inner-Rhoden, and Appenzell Äusser-Rhoden have preserved their ancient democratic assemblies (*Landsgemeinden*), in which all male citizens of full age meet annually (on the last Sunday of April or—in Glarus—on the first Sunday of May) in the open air for the purpose of legislation, taxation, and the election of an annual administrative council and of the members of the cantonal supreme court. In the remaining cantons the legislature (*Kantonsrat*, *Grosser Rat*, or *Grand Conseil*) is composed of representatives chosen by universal male suffrage (Vaud and Neuchâtel added female suffrage in 1959, Genève in 1960) and usually by proportional representation. These councils deal with legislation and all questions not reserved to the federal government. They decide on cantonal taxes and appoint judges as well as cantonal representatives to the federal *Ständerat* (Council of States) unless the cantonal constitution demands public elections. The executive also in most of the newer cantons is elected by a popular vote and not as hitherto by the cantonal legislature. All cantons have the referendum and the popular initiative, the application of which varies.

**Communes.**—These are the real units, the actual seats of self-government. Their structure and functions vary according to past history (communes of burghers, communes of residents, political communes, parishes, etc.). The two principal types are the burgher communes (*communes bourgeoises* or *Bürgergemeinden*) and the political communes (municipalities or *Politische Gemeinden*).

The burgher communes are now mainly of historical interest, having been gradually absorbed by the other type. The communal duties were largely increased after the liberal movement of 1830; the responsibility for roads, police, schools, and the administration of the poor law being successively handed over to them. Swiss citizens from cantons other than those in which they resided were, by the 1848 constitution, given voting rights there in cantonal and federal matters, but not in those relating exclusively to the commune. The 1874 constitution gave communal voting rights to all Swiss who could prove at least three months' residence.

Minor communes are controlled by a small council (*Gemeinderat*) chosen by a general assembly of all male (in the cantons of Genève, Vaud, and Neuchâtel also female) Swiss citizens over 20 years of good conduct, and with three months' communal residence. In the larger communes a legislative body and an executive council are elected by universal suffrage. The executive council presided by a mayor (*Gemeinde- or Stadtpräsident, syndic, or maire*) has the management of all local affairs, including the enforcement of cantonal and federal laws or decrees, except matters relating to the burgher communes. Most communes take advantage of the referendum and initiative.

**Districts.**—These comprise a group of communes under a prefect (*Regierungstatthalter*) who represents the cantonal government, supervises the application of cantonal law, and in certain cantons serves as first judge in minor administrative and police affairs.

**Constitution and the Confederation.**—On the cessation of the federal pact of 1815 a new constitution was accepted by general consent in 1848. A total revision was made in 1874 and this, with modifications, is the one now in force. Any revision or amendment introduced by an initiative, on the demand of 50,000 franchised male citizens or by the federal parliament, needs a referendum decision with a majority of votes of the people as well as of the cantons.

Federal sovereignty is exercised by the Federal Assembly (*Bundesversammlung*—legislative) and by the Federal Council (*Bundesrat*—executive), both meeting at Bern. The Federal Assembly consists of two chambers of equal rights: the National Council (*Nationalrat*) and the Council of States (*Ständerat*).

The Swiss people are represented in the National Council by 200 deputies. Each canton and half-canton forms an electoral district and is guaranteed at least one representative. The deputies receive attendance pay and traveling expenses from federal funds; neither allowance is lavish. A general election of representatives to the National Council takes place every four years; voting is by proportional representation with universal male franchise for persons of 20 years of age or more, and any voter, other than a clergyman, may be elected a deputy. The Council of States consists of two members from each canton or one from each half-canton, i.e., 44 in all. The mode of their election, term of membership, and rate of pay are entirely cantonal matters and vary accordingly. Laws passed by the Federal Assembly (though this body represents both people and cantons) can be vetoed by a majority-supported referendum based on popular demand by 30,000 enfranchised citizens.

The seven members of the Federal Council are elected for four years by the Federal Assembly and are responsible for the following departments: foreign affairs; interior; justice and police; defense; finance and customs; public economy; and transport, communications, and power. No canton may have more than one representative in the Federal Council; but according to custom the cantons of Zürich, Bern, and Vaud are represented; also the three main language groups (German, French, Italian) are usually represented proportionally to their numerical strength.

The president of the Federal Council (president of the Confederation) and the vice-president are elected for one year only (Jan. 1-Dec. 31) by the Federal Assembly and cannot be immediately reelected. The vice-president invariably becomes president the following year. Federal councillors cannot hold any other office and must not engage in any profession or trade. The federal government is being increasingly entrusted with matters formerly considered to be purely cantonal.

**2. Political Parties.**—There are nine parties represented in the National Council. The principal parties are the Sozialdemokratische Partei der Schweiz (Swiss Social Democratic Party), the Radikal-Demokratische Partei (Radical Democratic Party), and the Konservativ-Christlichsoziale Volkspartei der Schweiz (Swiss Christian Conservative Party). At the 1963 election to the National Council these parties won 53, 51, and 48 seats respectively. Other parties include the Bauern, Gewerbe und Bürger Partei (Peasants', Artisans' and Middle Class Party) (22 seats) and the Landesring der Unabhängigen (Independent Party) (10 seats). The Federal Council is composed of six members of the three larger parties (two from each) and one member of the Peasants', Artisans' and Middle Class Party.

The Council of States (elected 1963 by the cantons) consists of 18 Christian-Conservatives, 13 Radical-Democrats, 4 members of the Peasants', Artisans' and Middle Class Party, 3 Social Democrats, 3 Liberal-Democrats, and 3 Democrats.

**3. Taxation.**—Direct and indirect taxation, based upon federal and local laws accepted by general vote, are imposed differently by the communes, the cantons, and the Confederation. Up to 1915 the Confederation could levy only indirect taxes. A temporary constitutional amendment (approved in 1963 and in force from 1965 to 1974) gave a constitutional base for direct federal tax upon income and wealth. Rates of taxation in cantons and communes are fixed each year by decision of the voters or of the communal or cantonal parliament. Taxes are lowered for married people and further reduced if they have dependents under the age of 18 (25, if the dependent has not yet finished professional education).

**4. Living Conditions and Employment.**—The national income has been increasing constantly since 1945 and by the mid-1960s exceeded 55,000,000,000 Fr. (U.S. \$12,700,000,000) or 9,650 Fr. (\$2,244) per capita. As extremely high individual incomes are rare, the repartition of the national income appears tolerably bal-

anced. In spite of a growing inflation the average income of a Swiss worker showed an increase in buying power of more than 30% in the decade and a half after 1949. Unemployment is very low and the postwar economic development caused a strong influx of foreign labour, mostly from Italy, though this was curbed by restrictions in early 1965; 30% of the working population (which numbered about 2,700,000 in the mid-1960s) are non-Swiss citizens. Nearly one-half of the workers are employed in industry and handicrafts and about one-eighth in commerce, banking, and insurance. Agricultural workers have declined to about one-tenth. The population growth in general and especially in urban-industrial areas has provoked a housing shortage.

**Trade Unions.**—By the mid-1960s there were more than 30 unions with a combined membership of 782,000. The Schweizerischer Gewerkschaftsbund (Swiss Federation of Trade Unions) with 451,000 members had politically Social-Democratic tendencies. There were no Communist-dominated trade unions. Since the depression of the early 1930s trade unions have gradually denounced the use of strikes as economic or political weapons. Disputes are usually settled by arbitration.

**5. Welfare Services.**—The law stipulates that assistance to the poor is primarily the concern of the family. Public welfare services were developed in a typical federalistic way: first in communes, then in the cantons, and later in the Confederation. Social insurances that were introduced by amendments to the federal constitution already existed in some communities. The most important was the compulsory old age insurance (introduced in 1948, extended in 1960 to cover invalidity) which provides annuities and rent allowances to all people over 65, widows, orphans, and invalids; it is financed by contributions from every worker under 65 and by smaller contributions from the cantons and the Confederation. The contributions (4.5% of incomes) are shared jointly with the employer and determine the amount of rent to a fixed maximum. The old age subsidy does not cover the cost of living; communes, cantons, and the Confederation provide additional support for destitutes out of general revenues. Compensation for loss of earnings due to military service is similarly financed by contributions of 0.3% of incomes.

**6. Justice.**—Each canton elects and maintains its own magistracy for ordinary civil and criminal trials. Civil and penal laws are federal laws, but the laws of procedure and the execution of the penalties in criminal cases are left to the cantons. Capital punishment was abolished by the unified federal penal code of 1938, except under martial law, general mobilization, or war.

The Federal Supreme Court (*Bundesgericht*) sits at Lausanne. Its members (plus the supplementary judges) are elected by the Federal Assembly to hold office for six years. The Federal Assembly also elects every two years the president and vice-president who cannot be immediately reelected. The original and final jurisdiction of the Federal Supreme Court extends to disputes between the Confederation, local governments, and private individuals, so far as these differences refer to federal matters and involve more than 8,000 Fr. in financial suits. It is a court of appeal against cantonal authorities in the application of federal laws and also against certain federal decisions. It is a court of trial for persons accused of treason or other offenses against the Confederation, and a court of cassation in criminal trials. The four courts of the *Bundesgericht* are the Court of Accusation, the Criminal Court (with paid jurors elected by the people), the Federal Penal Court, and the Court of Cassation.

(W. E. WH.; ER. M.)

**Police.**—Authority in general is exercised by the cantons but larger communes also maintain police forces. A small federal police corps enforces (mainly in collaboration with cantonal police) special federal laws concerning treason, forgery, etc.

**7. Education.**—The 1874 constitution stipulates that each canton or half-canton is sovereign in education, that elementary education is compulsory and free, that all public schools must be state directed, and that religious freedom be guaranteed. The Confederation financially assists public elementary schools and vocational training, and by regulating examinations for the professions it also influences the curriculum of the higher middle schools. The

only institution of higher education maintained by the Confederation is the Eidgenössische Technische Hochschule (Federal Institute of Technology) at Zürich. The Interior Department in Bern administers education and there is an education department in every canton.

Children attend primary schools between the ages of 6 and 13, but can enter secondary and lower middle schools which form a link with higher or vocational schools. Pupils enter higher schools between 11 and 13, remaining for two to five years, and are grouped in language-history and mathematics-science branches. Technical or vocational schools serve apprentices between 15 and 19. The higher middle schools either take pupils from the senior classes of primary schools or themselves provide the preparatory schooling. They prepare pupils for higher school certificate in three types of curriculums: classical (with compulsory Latin and Greek), modern language, and science. There are boys', girls', and coeducational institutions. By the mid-1960s the number of pupils at primary schools totaled about 600,000 (with 23,000 teachers); at secondary and lower middle schools 150,000 (with 6,000 teachers); and at technical and vocational schools 15,000 (with 400 teachers).

In addition to the Eidgenössische Technische Hochschule (founded 1855), there are eight cantonal universities; viz., Basel (1460), Lausanne (1537) with the École Polytechnique de l'Université de Lausanne (1853), Geneva (1559), Zürich (1833), Bern (1834), Neuchâtel (1838), Fribourg (1889), and Sankt Gallen (1898). At Lausanne, Geneva, and Neuchâtel instruction is given in French; at Basel, Zürich, and Sankt Gallen in German. Swiss universities are lay (*laïques*), but all, except Fribourg, are in cantons of Protestant tradition. At Basel, Geneva, Lausanne, Neuchâtel, and Zürich the theological faculties are Protestant; at Bern there are Protestant and Christian-Catholic faculties; at Fribourg only a Catholic one. Of about 28,000 students in the mid-1960s nearly one-third were foreigners.

**8. Defense.**—Being composed of militia, the Swiss Army contains no forces maintained permanently with the colours except a corps of 500 instructors—a system that is unique in Europe. The total number of men trained for military duty was approximately 600,000 in the mid-1960s. Military service is compulsory and all male citizens from the age of 20 to 50 (officers to 55) are liable. Citizens unfit for duty must pay a military tax. Obligations of militiamen also include the maintenance of public order and security. After physical training for youths, provided by the cantons under the supervision of the federal government, the training is carried out under the defense department. Women between the ages of 20 and 40 years may volunteer for service in the unarmed women's auxiliary force (*Frauenhilfsdienst*).

The army comprises a first line (*Auszug* or *Elite*) of men between 20 and 32, a *Landwehr* for men aged 33 to 42, and a *Landsturm* for those between 43 and 50. After 118 to 132 days of basic training members of the *Elite* undergo seven annual trainings of 20 days. Men in the *Landwehr* and in the *Landsturm* are called up for several refresher courses not exceeding 53 days in all. Officers are trained in cadet schools, courses lasting from 67 to 104 days, according to the arm of the service envisaged. As the militia keep their uniforms and small arms in their homes, the whole army can be rapidly mobilized.

The country has 4 army corps and 12 divisions. There is a staff organization for the army corps and a general army headquarters in the National Alpine Redoubt. The 37 infantry regiments are equipped with automatic arms, mortars, and antitank weapons. The 17 artillery regiments are armed with 105-mm. guns and 105-mm. and 150-mm. howitzers. The air force in the mid-1960s comprised 21 squadrons and 400 first-line jet aircraft.

In 1950 Switzerland embarked on an extraordinary rearmament program with an annual expenditure of about 1,600,000,000 Fr. By the mid-1960s annual military appropriations amounted to about 1,500,000,000 Fr. and modernization programs were underway.

In peacetime the Swiss army has no commander in chief (general), commander of army corps (colonel) being the highest rank. If troops are mobilized on a large scale the federal assembly nominates a commander in chief, as it did in 1939 when Gen. Henri

Guisan was appointed. There is a general staff under the Defense Department in Bern and a National Defense Committee, with the defense councillor as chairman, and the chief of the general staff, the chief of instruction, the army corps commanders, and the air force commander as members. The committee ceases to function when a commander in chief is appointed. (K. Sm.; Er. M.)

## VI. THE ECONOMY

Landlocked, largely mountainous, with a damp climate and few useful mineral resources, Switzerland was endowed by nature with no more than the basis of a meagre pastoral economy. However, by skill and hard work the inhabitants have made it one of the most highly industrialized countries of Europe with a high standard of living. The economy supports not only the native population but also a sizable labour force from abroad.

Between 1800 and the mid-20th century the farming population fell from nine-tenths to about one-tenth of the total. Half the economically active population is now employed in manufacturing, building, and handicrafts. With its skilled labour force and intensive capital investment, Swiss industry can produce, largely from imported raw materials, items such as clocks and watches and precision instruments which can compete in distant markets by virtue of a high unit value relative to their weight.

An important consequence of continuing Swiss neutrality has been economic stability, at times in the midst of European chaos.

### A. PRODUCTION

**Agriculture.**—Largely because of its mountainous character, little more than half the land is suitable for agriculture. Stock breeding and dairying are the mainstays of Swiss farming. There is nearly four times as much meadowland as arable (including orchards, market gardens, and vineyards), and the area of moun-

tain pastures is almost as great as that of meadows. Despite natural handicaps farming is highly efficient, as shown by the high annual yields of the mid-1960s: wheat, 3 metric tons per hectare (1.2 per acre), and milk, 3,000 litres (792.5 U.S. gal.) per cow.

Most intensively worked are the "vine farms" and those equally small farms that specialize in the growing of vegetables, fruit, or tobacco. The vine farms, found particularly along the Lake of Geneva and in the Rhône valley, supply about half the country's requirements of wine. There are pear and apricot plantations in the upper Valais, but fruit farming is subsidiary in the Mittelland where apples, pears, cherries, and plums are grown. Half the bread grain requirements are supplied by the home crop, which accounts for most of the arable land, chiefly in the Mittelland. Other crops include potatoes, oats, barley, rye, and sugar beet.

Stock raising accounts for most of the farmers' gross income. The greatest concentration of cattle is in the northern foothills of the Alps, but cattle farming is important everywhere. Many cattle spend the summer on the mountain pastures. About one-quarter of the milk is used for cheeses (*e.g.*, Emmentaler, Gruyère, and Sapsago), the principal agricultural export. Almost all the cattle are either of the Brown Swiss or Red-flecked Simmental breeds. Pigs are numerous but goats and sheep are declining.

Swiss farming is characterized by the owner-occupied family farm. Roughly half the farms are smaller than 12 ac. (5 ha.) and another quarter are between 10 and 25 ac. (4 and 10 ha.). Efficiency has been increased by a reduction in the number of farms and the growth of producing and marketing cooperatives. The interests of agriculture are represented by a central body, the Schweizerischer Bauernverband (Union Suisse des Paysans, or Swiss Farmers' Union).

**Forestry.**—Woodland covers nearly a quarter of the country's

(LEFT) ROBERT PERRON—PHOTO RESEARCHERS, INC.; (TOP CENTRE) SLIM AARONS—PHOTO RESEARCHERS, INC.; (TOP RIGHT) FRITZ ESCHEN; (BOTTOM RIGHT) HENRI CARTIER-BRESSON—MAGNUM

(LEFT) HILLSIDE PASTURE LAND IN APPENZEL; (TOP CENTRE) HAYING ON ALPINE SLOPES NEAR BÜRGENSTOCK, NIDWALDEN HALF CANTON; (TOP RIGHT) MORCOTE, A SMALL TOWN ON THE LAKE OF LUGANO; (BOTTOM RIGHT) MEDIEVAL WOODEN BRIDGE ACROSS RHINE AT STEIN AM RHEIN, ON THE SWISS-GERMAN BORDER, SCHAFFHAUSEN CANTON

surface but its direct economic value is small, for the bulk of it serves to protect settlements and communication lines against injurious climatic effects (e.g., avalanches, rain floods, soil erosion) and is restricted in its exploitation. More than two-thirds consists of conifers, chiefly spruce and fir, the remainder being largely beech. About 70% of the forest belongs to the community and to public legal bodies; the rest is privately owned, mainly by farmers.

**Mining.**—There is a paucity of minerals, except for salt, which is mined at such places as Rheinfelden and Ryburg near the High Rhine. The mining of metal ores, of great importance up to the 19th century, is now confined to iron and manganese ore in the Jura Mountains and elsewhere. The meagre coal deposits are exploited only during fuel shortages. Limestone quarrying in the Alps and Jura is the basis of the cement industry.

**Power.**—Switzerland's shortage of solid fuel is largely counterbalanced by its great resources of water power which is harnessed by more than 300 hydroelectric plants. Since most of the power stations are of the "run-of-the-river" type, there is a summer production peak when the rivers have their maximum flow and electricity is exported. In winter production is supplemented by high-pressure reservoir-fed power stations in the High Alps, but winter imports of electricity are still necessary.

**Manufacturing Industries.**—There is a large and growing number of factories employing about two-fifths of the total labour force. Nearly one-third of the workers are employed in small concerns with less than 50 workers each. Characteristics of Swiss manufacturing are its high degree of specialization, its great dependence on imported raw materials or semifinished goods, and its reliance on foreign markets. More than two-thirds of the manufacturing labour force work in the four great export industries: textiles and clothing, metal goods, clocks and watches, and chemicals.

Significant enterprises based wholly or largely on indigenous raw materials are the food industries; these include the production of condensed and powdered milk, chocolate, soup preparations, sugar, and beer, and the canning of fruit and vegetables. The cellulose and paper industry needs additional imports of timber. Salt and electric energy are inherent bases of the chemical industry, which has its greatest concentration around Basel. Electricity is also the basis for the production of aluminum (from French bauxite), mostly in Valais. Production of pig iron and crude steel covers only a fraction of home requirements.

The engineering industry has the largest share of the industrial labour force and exports two-thirds of its production. It is centred on Zürich Canton, where it arose to satisfy the needs of the textile industry. It expanded to include turbines and electrical equipment, and finally machine tools and precision instruments, now its most important branch. The textile industry, second in size of labour force and exporting nearly half its products, is still located in eastern Switzerland. The boot and shoe industry is largely based on Schönenwerd (in Solothurn). The most characteristic of Swiss industries is watch and clock making. In no other industry is the raw material cost so relatively small or production so much orientated toward export (more than 90%). The earliest site of the industry was Geneva, but the various places in the Jura (e.g., La Chaux de Fonds, Le Locle, and Ste. Croix), taken together, are now more important.

Switzerland, with its spectacular alpine scenery, its lakes, resorts, and spas, has attracted tourists since the early 19th century and remains one of the principal tourist countries of Europe.

## B. TRADE AND FINANCE

**Foreign Trade.**—Imports exceed exports, for Switzerland must buy not only raw materials and fuel but also much of its food. However, earnings from year-round tourism cover about half the visible trade deficit, the remainder being met from such items as receipts from insurance and banking services and transit companies. Also the size of the monetary reserves (in gold and currency) held by the banks and credit establishments has helped the government to withstand such deficits in the balance of payments. Nearly two-fifths of exports comprise metallurgical and engineering

goods, followed by chemicals, clocks and watches, and textiles. The Swiss have always keenly supported international moves to liberalize trade and in that spirit joined the European Free Trade Association. At the same time they hope eventually to form a multilateral association with the European Economic Community which by the mid-1960s had become their chief trading source, with the Federal Republic of Germany as the principal partner.

**Finance.**—The unit of currency is the Swiss franc divided into 100 centimes with an exchange rate in the mid-1960s of approximately Fr. 4.32 to U.S. \$1 and Fr. 12.1 to £1 sterling. The central bank of issue is the Swiss National Bank (founded in 1905; opened in 1907). The currency has proved a strong one and has always been fully convertible. Thus in the first half of the 20th century Switzerland, politically stable and neutral, became one of the leading financial centres of Europe exporting capital for investment. In this respect Zürich is now more important than Basel and Geneva. The three largest banks are the Swiss Credit Bank, the Union Bank of Switzerland, and the Swiss Bank Corporation. Swiss international bankers and entrepreneurs are celebrated for sound financial practice and for their skill in business and commerce.

The central government's income is derived from the capital levy and customs and excise duties, together with half the yield from the military-exemption tax and stamp duties. By the mid-1960s budget revenue (nearly Fr. 5,000,000,000) showed a moderate excess over expenditure. The gross national product was about Fr. 50,000,000,000.

## C. TRANSPORT AND COMMUNICATIONS

Control of the most important alpine passes and the ancient routeway through the Mittelland between the Rhône and Danube waterways give Switzerland a key position in European transit traffic. The main artery of European transalpine traffic, the St. Gotthard route, runs through Swiss territory. Historically, other routes, such as the Great St. Bernard and Simplon passes, were of earlier importance. (See ALPS: *Principal Passes*.)

**Roads.**—The right to build roads was largely reserved by the cantons until 1958 when a federal plan was drawn up for a network of national *Autobahnen* (motorways) to be completed by 1980. The first stage envisaged extension by 500 mi. (800 km.) of the more than 10,600 mi. (17,100 km.) of main roads. Some mountain passes are impassable in winter, but at St. Gotthard and Simplon cars are ferried through the tunnels by rail; there are motorway tunnels beneath the Great St. Bernard Pass and another tunnel is projected beneath the San Bernardino.

**Railways.**—For general traffic these cover more than 3,100 mi. (5,000 km.). There are also special rack and pinion (cogwheel) and funicular railways and aerial cableways. Switzerland's first railway line was inaugurated in 1847, and a federal railway system began operating in 1899, but many "private" companies (actually financed from municipal, cantonal, and state funds) remain, mostly running narrow-gauge railways. Because of availability of water power, electric traction was begun early; almost all railway lines are now electrified. Railway construction was expensive, for numerous bridges and tunnels had to be built: the Simplon Tunnel, more than 12 mi. (19 km.) long, is one of the longest in the world (see TUNNEL). Cogwheel and cable railways were pioneered in Switzerland, and the first funicular cable railway was built at Engelberg in 1927.

**Shipping.**—There are passenger shipping services on 13 lakes and on parts of the Aare and High Rhine. Canalization of the entire High Rhine is planned, to make the Lake of Constance the terminus of the Rhine navigation. Cargo shipping below Basel provides a direct link with the Lower Rhine ports and the sea. There is a small merchant navy (created by a government decree in 1941), of ocean-going vessels, comprising more than 30 ships which are registered at Basel. But the Rhine fleet has more than 400 units.

**Civil Aviation.**—The airports of Zürich (Kloten) and Geneva (Cointrin) are important junctions of European air routes. The national airline, Swissair, founded in 1931, is privately controlled with some state participation.

**Postal Service and Telecommunications.**—The unification of postal services on a federal basis took place with the Swiss constitution of 1848. The Universal Postal Union was founded in 1874 at Bern, where its secretariat remains. The Swiss telephone service is excellent and is integrated in a single dial system. There are national radio transmitters at Beromünster, Sottens, and Monte-Ceneri, and a shortwave centre at Schwarzenburg. Programs are conceded to the Schweizerische Radio-und-Fernsehgeseellschaft (Société Suisse de Radiodiffusion et Télévision) at Bern, which also directs the television service inaugurated in 1958. See also references under "Switzerland" in the Index.

Current history and statistics are summarized annually in *Britannica Book of the Year*.

**SWORD**, a hand weapon with a sharp metal blade that is longer than that of a dagger, though the distinction between sword

and dagger is somewhat arbitrary. "Sword" is a general term that includes many special types of weapons, such as sabres, rapiers, scimitars, etc.

**Early History.**—It is possible that the earliest swords derived from the flint daggers of the Neolithic period, which may have been the models for the first hand weapons made of copper. Daggers with copper blades found in Mycenae have hilts attached to the blades by rivets. An important step in the construction of both sword and dagger was taken when the blade was continued in an extension, or tang, which became the core of the handle. The blade and hilt could thus not easily be broken apart by a blow. Most swords of the Bronze Age had leaf-shaped blades and small hilts. They have been excavated in large numbers throughout Europe. Swords of this kind (*ziphos*; *akinakes*) were used in the Homeric period, and are shown in paintings on Greek vases of the Hellenic period. Alternatively to the straight-edged, leaf-shaped sword was the so-called Bronze Age rapier, a sword with a long narrow blade for thrusting only.

In classical times the sword as a weapon was subsidiary to the spear. The Roman soldier's sword (*gladius*) was generally short, straight and broad, though a longer type of sword, known as the *spatha*, was also used. The word *ensis* was generally applied to swords of tribes outside the empire.

The Franks of the late Iron Age continued to use the long *spatha*, but as it was made of soft iron, the blade was easily bent. Some protection for the hands was given in early swords by the form of the hilt, but it was not until the early middle ages that the crossbar, or *quillon*, became fully developed for protective purposes.

By the 6th century Viking swords began to take the form that lasted for a thousand years. The sword had then acquired its four principal parts: (1) the pommel, a knob at the anterior end, which acted as a counterpoise to the blade; (2) the grip, covering the tang and grasped by the hands; (3) the crossbar or *quillon*, which protected the user's hand; and (4) the blade. (See figure.)

**The Middle Ages.**—It was the Vikings from Scandinavia who introduced the sword with the blade of carbonized iron. There has always been a mystery about the making of sword blades, hence the legends of Weyland the Smith, Siegfried's sword "Nothing" and King Arthur's "Excalibur." Modern science has discovered that some of these blades, which have patterns or "watering" inherent in them, were produced by what is called strip welding. Bundles of iron strips were bent over, hammered together, cut and bent again repeatedly, and the carbonization of metal, probably discovered accidentally, improved their strength and temper.

The Viking sword, and its successor, the medieval knightly sword, usually had a straight blade, double-edged and pointed, with a shallow hollow down the centre, giving lightness with rigidity. The medieval sword was purely an offensive weapon; the user relied for bodily protection on his shield and defensive armour. The user's hand was protected by rigid *quillons*, either straight or with the ends curved toward the blade. The pommel was usually rounded, either as a sphere or a disk (so-called wheel pommel) and later fig-shaped.

In the course of years certain European centres of the craft were established, notably at Passau on the Danube, and later at Solingen in western Germany,

(Top left) Bronze Age sword; (top centre left) Viking sword; (top centre right) Roman sword in scabbard, A.D. 43–60; (right) two-handed German swords, about 1580; (above) heading sword with sheath, probably Hungarian, about 1620

where the craft was still active in the mid-20th century. Blades were exported from Solingen to all parts of Europe, often bearing the mark of a running wolf. Swords bearing distinctive names, denoting a common origin, were widely distributed in Europe, such as those inscribed Ulfbeht and Ingelred. Other centres of the sword cutler's craft were places where the making of arms and armour in general had been established, notably in Milan in north Italy, and in the south German towns of Nürnberg and Augsburg. In Spain great skill was shown by the swordsmiths of Toledo. The names of many master craftsmen are known and are found engraved upon the blades themselves, which also carry the marks of the maker and often the city guild where they were proved.

In the late middle ages the knightly sword was sometimes lengthened, both in blade and hilt, and the latter so shaped that it could be grasped by both hands if necessary. In the 15th century the blades of straight-bladed swords were more usually double-edged and flat, sometimes stiffened by a sharp ridge down the centre. This was particularly the case in Italy. A purely thrusting sword, with a rigid blade, was known as an *estoc*. At the turn of the century the big two-handed sword had a short vogue, but the space needed to wield it tended to limit its advantages.

In order to have better control of the weapon, a custom developed of passing the right forefinger over the *quillon*. To protect it, a metal hook or ring was placed in front of the *quillon*. The next step was to place a corresponding half ring on the other side of the blade for the sake of symmetry. This development, nicknamed the *pas d'âne* from its resemblance to a cloven hoof mark, apparently developed first in Spain and then passed to Italy before

the end of the 15th century. It is important as foreshadowing the development of the hilt whereby the hand was protected by a cage-like series of rings and bars forming part of the sword instead of by a steel glove.

**The Later Sword.**—The sword underwent rapid changes in Europe during the first half of the 16th century, and proliferated in a variety of forms. These changes correspond with the period when defensive armour was beginning to fall into disuse, and special corps of soldiery were becoming components of national armies. The protection of the hand was carried a step farther by the provision of a knuckle bow; i.e., a semicircular bar extending from the *quillon* toward the pommel. The next move was to add additional rings to guard the whole hand, both in the vertical and the horizontal planes. The old arming sword, which was wielded with a gauntleted hand, had been strictly cruciform. The 16th century saw the arrival of the rapier, with a long, narrow blade, and with the hand protected by a series of guards and counterguards.

The habit of carrying a sword with civilian dress had not been universal in the middle ages but it later became the custom for every gentleman to carry a rapier in civil life, and in consequence dueling increased. Previously, dueling had taken the form of judicial combats, conducted with strict formality. Dueling with a rapier rapidly encouraged the art of fencing. Schools conducted by masters of fence were set up to enable gentlemen to learn their skill at arms. The earliest known fencing book is a treatise, *Flor Duellatorum* or *Il Fior di Battaglia*, by Maestro Fiore dei Liberi (compiled in Italy in 1410). It demonstrated in a series of drawings combats with swords, sword and buckler, wrestling, etc. It was followed in the 15th century by a picture book by H. Talhofer, of which several manuscript versions exist. In the 16th century, books on fencing came from the printing presses, generally written by one of the masters of the schools of fencing, such as A. Marozzo and C. Agrippa in Italy, H. de St. Didier in France and George Silver, who was a stout defender of the rough-and-ready English fashion against his rival, "Signior" Rocco, an Italian who had set up his own school in London. The weapons used in dueling could be rapier and dagger (the latter held in the left hand and used for parrying), rapier and cloak, or two rapiers, but eventually fencing with the rapier or smallsword alone prevailed. At first both edge and point were used, but with the increase of manual dexterity it was found that the point, which allowed a long reach, was more effective by itself. The swordsmen were liable to lay themselves open when he used striking blows, so thrusting, parrying and feinting within a narrow compass became a practised art. (See also FENCING.)

The hilts of rapiers took many forms, often being richly decorated with gold and silver, damascening, enameling and even incrustation with jewels. Fine specimens are to be seen in the national armouries of Vienna, Madrid and Paris. Notable sword-makers were A. Piccinino of Milan, L. Palumbo of Naples, the Wundes family and Clemens Horn, among many, at Solingen and Juan Martinez, Tomas de Ayala and Sebastian Hernandez at Toledo. The blades of most rapiers bear the signature of the maker, his town, and the stamp of the city guild, which is usually placed upon the *ricasso* (the base of the blade), which usually has a rectangular section. Many of these long, narrow, thrusting blades made in Germany were stamped with imitations of the stamp of Toledo. Blades of all kinds were made in Germany inscribed with the names of swordsmiths who may be regarded as having specialized in blades of a certain kind, such as A. Sahagun and Andrea Ferrara. The last name is quite commonly found on the blades of broad swords of the 17th century and is

(Above) Persian solimtar and sheath with early-18th-century mounts and late-16th-century blade; (right) Gurkha kukris with sheaths and accompanying small blades: the kukri at right is an engraved presentation piece, given to Gen. Sir John Coleridge by officers of the Gurkha Rifles

no indication of the actual maker. The blade is classified in two parts, the *forte* which is the anterior part, and the *foible* which is the forward part farthest from the hilt. In Spain a particularly elegant form of rapier hilt was developed in which the principal protection of the hand was a steel cup, often beautifully pierced with decorations. This developed at Toledo, but soon spread throughout much of western Europe. Generally speaking, those made in the south had deep cups while those produced in the Low Countries and England had shallower "dish" guards.

In the third quarter of the 17th century the rapier was reduced in size and simplified to what became known as the smallsword. This too was principally a civilian weapon, and the subject of much delicate and elaborate ornamentation. The blade of the smallsword was purely for thrusting, and usually had a hollow, triangular section. In other cases the blades were hexagonal, diamond-shaped or even elliptical in section.

New weapons produced their own writers on swordsmanship, notably the Scotsman, Sir William Hope, who wrote a number of manuals in the late 17th and early 18th centuries. H. Angelo's school of fencing in London is well known from his books illustrated by George Rowlandson.

Swords for specialized use and local types are legion, such as the straight broadsword with S-shaped *quillons* used by the German *Landsknechte* (professional infantry) in Germany and Switzerland in the 16th century. In the highlands of Scotland the two-handed sword lasted to the end of the 17th century in the form of the big *claidheamhor* (great sword; whence "claymore") with drooping *quillons* ending in quaterfoils, and Scotland produced a characteristic variety of the basket-hilted broadsword.

The medieval arming sword had been replaced for war by the sword rapier, a heavier version of the civilian sword. Its successor was the cavalry broadsword, a simple and handy weapon on which the knuckles were protected by a single or basketlike guard, and the blade was flat and broad, sometimes double-edged and sometimes single, when it was called a backsword. Many broadswords of this type have come down from the time of the Civil War in England. Sometimes the solid guards of the hilts are chased with the heads of Charles I and his queen, and these are popularly called "mortuary" swords, referring to the execution of the king. The military form of the smallsword in the 18th century was more heavily built; further, it had a single knuckle bow and a pair of oval-shaped plaques in front of the *pas d'âne*.

**The Curved Sword and the East.**—The sabre is essentially a cutting weapon, with the blade sharpened on the convex edge only. It cuts well because only a small part of the arc first reaches the objective, and then bites into it.

Whereas the straight sword was the favourite in the west, the curved sword predominated in eastern Europe and Asia, although curved swords were not unknown in the west. In the middle ages there was the falchion, a sword with a cleaverlike blade, broadening toward the point and with a single curved cutting edge. That it was regarded as an oriental weapon is shown by the fact that in medieval manuscripts the sleeping guards at the Sepulchre are shown with falchions.

The Turkish invasion of Eu-

rope in the 16th century brought the west into close contact with the curved weapons of the east. The scimitar, which has a keen arc-shaped edge, derived from the Persian *shamsheer*. It was brought into Hungary and Poland, and western cavalry regiments in the late 18th and 19th centuries were armed with the curved sabre which derived directly from the east.

Turkish and Persian scimitars were often made with finely watered blades. These blades are often described as damascened, but Damascus was never a centre of the craft, only an entrepôt. Fine swords were made at Isfahan in Persia, at Constantinople, at Cairo under the Mamelukes and at Fez in north Africa. The north and middle European scimitar generally has a pistol-shape grip, which continues the curve of the blade in the opposite direction.

In India the scimitar is called a tulwar. Other Indian swords are the Maratha *khand* and the gauntlet sword known as a *pata*, and in Burma the *dha*. The Gurkha *kukri* has a doubly curved blade, and can be used to decapitate an ox at one blow.

In Japan the sword has long been highly regarded. As early as the 13th–14th centuries great masters of the craft were making blades of remarkable quality, such as Yoshimitsu and Masamune. The possession of a sword is closely connected with the cult of ancestor worship, and swords were handed from one generation to another as objects of veneration. The Japanese sword has a long, slightly curved, single-edged blade and a two-handed grip in which the curve is extended in the same direction as that of the blade. The guards (*tsubas*), which are small and solid, are objects of special decoration; an owner might have as many as sixty different guards for his sword. Among the various kinds of Japanese swords are the *daisho*, a pair of swords, the larger being called a *katana* and the smaller a *wakizashi*. Swordsmanship was possibly an even greater cult in Japan than in the west, and expressed itself in formal and elaborate dueling.

**The Modern Sword.**—Since the middle of the 18th century the sabre has been predominant. Indeed, more than 80% of all European and American swords of the period fall within this category. The civilian small sword had virtually disappeared by 1800. Diplomats and some staff officers continued to wear small swords

IN THE TOWER OF LONDON; BY COURTESY OF MINISTRY OF PUBLIC BUILDINGS AND WORKS

(Left) Three 19th-century English cavalry sabres: (top right) Spanish cup hilt rapier, mid-17th century, formerly in the collection of Frederick Augustus, duke of York (1763–1827); (centre) Italian rapier, late 16th century; (right) swept hilt rapier with Italian blade and, probably, German hilt, about 1590

of one type or another, but their numbers were few. Among the military sabres, those used by the cavalry were most important as weapons. The first sabres to be used by horsemen were usually straight or very slightly curved. Early in the 19th century the curve increased. Then, with the discovery that the point was used more often than the edge, the straight blade returned to favour. Another form of sabre, the naval cutlass, achieved its distinction during this era. It was a short weapon with a straight or slightly curved blade and a heavy guard suitable for fighting in close quarters and easily carried while climbing. It maintained its basic design until long-range naval actions of the twentieth century rendered it obsolete.

Officers and ranking noncommissioned officers of most arms and branches of service carried swords at some time during the 19th century. Indeed, the sword indicated rank and branch of service of the wearer. For this reason the swords of the last two hundred years are found in a greater variety of styles and forms than for any other comparable period.

As long as firearms were single-shot weapons and firepower was relatively low, the sword remained a vital weapon. During the American Revolution, cavalry leaders considered the sword the only true weapon of a trooper and scorned the use of firearms except for skirmish or picket duty. Infantry officers participated in charges with sword in hand or stood by with that weapon to help repel an enemy attack.

The adoption of repeating arms ended the sword's importance. As late as the U.S. Civil War cavalry still charged with sabre in hand, but the concept of the trooper as a mounted infantryman was developing. His revolver and his repeating carbine carried more weight than his sword. The last traditional cavalry charge by U.S. troops occurred on Luzon in 1906. There were some isolated actions by European cavalrymen during World War I and again on the eastern front in World War II, but these were anachronisms. The era of the sabre as a weapon had ended. As a symbol of rank and of arm of service, however, it is still in use; and it has been found to serve an important function from the standpoint of morale and the sense of tradition.

**Presentation and State Swords.**—A special category of swords comprises those used in state ceremonies and those presented to individuals as a mark of esteem or honour. The ceremonial or state swords have been used for many centuries at coronations, inaugurations and other solemn public occasions. Among them are the sword of justice, the sword of mercy and the sword of mourning. Usually they are huge two-handed swords richly mounted in precious metals, often set with gems, and frequently bearing the arms of the country, state or city to which they belong. Such swords have figured in the regalia of almost every European monarchy, and some are still in use. Special presentation swords or swords of honour have a much shorter history. The practice of giving a sword as a mark of esteem or as recognition for a heroic deed is as old as the sword itself. The manufacture of special swords for this purpose, however, did not achieve widespread popularity until the 18th century. From then until the third quarter of the 19th century huge quantities of them were made and presented by nations, states, cities, organizations and individuals. After 1875 the practice rapidly declined in popularity, although it has not yet died out completely. A few were presented to leading generals at the close of World War II. Usually these presentation swords were patterned after the principal swords of the day but distinguished from them by the richness of their mountings. In the 18th century they were primarily small swords; in the 19th century they were sabres. Most recently, however, there has been a tendency to revert to the mediaeval arming sword. Most of those presented at the close of World War II, in fact, were of this traditional form.

**The Headsman's Sword.**—One last class of sword may also be mentioned—the "heading" sword or executioner's sword. In many countries, both in Europe and Asia, it was often the practice to decapitate with the sword instead of the ax. Queen Anne Boleyn was beheaded with a sword at the Tower of London in 1536, and even in America at least one such execution is recorded in Massachusetts in 1644. In Asia the practice was still being used

as late as World War II. The European "heading" sword traditionally had a long straight blade with a square "point." Asian swords tended to curved blades.

**SWORD DANCE**: see **FOLK DANCE**: *Ritual-Ceremonial Folk Dances*.

**SWORDFISH**, a large, dark-purplish fish of all warm seas, with the upper jaw prolonged far beyond the mouth to form a vertically flattened "sword." The single species, *Xiphias gladius*, constituting the family Xiphiidae, is a highly regarded foodfish and has long been the object of commercial fishing in the Mediterranean and other seas. It is also highly prized as a gamefish though it is not taken nearly so often by sportsmen as are the marlins and sailfishes (qq.v.).

Both the swordfish and the marlins are thought to be related to the mackerel, which they resemble in the beautifully streamlined body. Although swordfishes may grow to nearly 20 ft. and weigh up to a half ton, most specimens have a range of 6-10 ft. and 100-250 lb. In swimming, these fishes rely on the powerful beating of the lunate tail fin rather than on the undulations of the body, as in most fishes. The strong muscles of the very thick body are connected by tendons with the tail fin, so that the contractions of these muscles beat the tail fin back and forth while the stiff body glides rapidly and straight through the water. It is generally thought that the sword is used primarily to stun other fish, since the swordfish (and the marlin) swings its head back and forth in passing through a school of fish. The food consists chiefly of small fish and squids.

See also **FISH**.

(C. L. Ha.)  
**SYBARIS**, an ancient Greek city in Italy, famous for the wealth and "sybaritic" luxury of its inhabitants, about whom largely apocryphal "Sybarite stories" of luxury and softness circulated in Greece for centuries. The city was situated on the Gulf of Tarentum, between the Crathis (Crati) and Sybaris (Coscile) rivers, which now meet about 4½ mi. (7 km.) inland but in ancient times may have had independent mouths. It was the oldest Greek

colony in this region, founded about 720 B.C. by Achaeans and Troezenians. Placed in a very fertile area, and readily granting citizenship to new settlers, the city became great and rich, with a vast subject territory and daughter colonies even on the west coast, including Posidonia (Paestum) and Laus. The Sybarites were successful in a war against Siris, a few miles to the north. The rise of a tyrant, Telys, with popular support led to the exile and flight to Crotona of many members and supporters of the ousted oligarchy. War followed, and the victorious Crotoniates razed Sybaris and turned the waters of the Crathis over its ruins (510 B.C.).

The Sybarites fled to their colonies, but some apparently maintained their corporate identity in the early 5th century. In 452 they refounded Sybaris, but it was destroyed by the Crotoniates five years later. The Sybarites obtained Athenian support for a third foundation, but the Athenians soon expelled them from the city. They founded a fourth Sybaris farther south on the Traeis (Trionto) River, and the Athenians founded Thurii (q.v.; 444/443).

The modern place-name Sibari is only an approximation to the lost site of Sybaris. Some cemeteries, including the 4th-century Thurii cemetery, were uncovered in the 19th century. In 1949 the fourth Sybaris was identified at Castiglione di Paludi, where there are walls, tombs, and a Greek theatre; and in the 1960s geophysical prospecting and trial digging near the Crati located traces of 6th-century Greek occupation.

See T. J. Dunbabin, *The Western Greeks*, esp. ch. 2, 4, and 12 (1948); F. Rainey in *Illustrated London News* (Dec. 8 and 15, 1962).

**SYBEL, HEINRICH VON** (1817–1895), German historian and politician, a leading exponent of the Prussian, or political, school of historical writing, was born on Dec. 2, 1817, at Düsseldorf. While studying in Berlin (1834–38), he learned from Ranke (q.v.) the critical method of evaluating historical sources, and his first book, *Geschichte des ersten Kreuzzugs* (1841; Eng. trans. 1861) is among the most distinguished products of the Ranke school. His study of German kingship, *Entstehung des deutschen Königtums* (1844), belongs to the same group.

Sybel's political interests soon separated him, at least academically, from Ranke, whose detachment he grew to despise as soulless respectability. He held professorial chairs at Marburg (1846), Munich (1856), and Bonn (1861), saying of himself that he was four-sevenths politician and three-sevenths professor, and he came to believe passionately in the historian's vocation as teacher. His involvement in contemporary politics was consistent with these views. He sat in the Hessian Landtag (1848), the Erfurt Parliament (1850), the Prussian Landtag (1862–64; 1874–80), and the Prussian Constituent Assembly of 1867. A believer in Prussia's mission to lead Germany toward unification, he was an enemy of ultramontanism and feudalism; he rejected medieval imperial policy (see the pronouncements in his controversy with J. Fricker, ed. by F. Schneider, 1941). Until the war of 1866 Sybel opposed Bismarck over finance and the Polish and Danish questions. He later withdrew his opposition and as a National Liberal in the Constituent Assembly supported Bismarck in the *Kulturkampf*.

Sybel's political views are clear from his later books. His greatest work, *Geschichte der Revolutionszeit von 1789 bis 1795 (1789 bis 1800)* (5 vol., 1853–79), which was particularly valuable for its connection of French domestic events with the wider European scene, showed vigorous opposition to revolutionary ideals. A constant adversary of radicalism, he preferred a moderate degree of self-government combined with individual freedom. His last work, *Die Begründung des deutschen Reiches durch Wilhelm I.* (7 vol., 1889–94), for which Bismarck opened the state archives, is the first detailed account of the subject. It is somewhat marred, however, by a disregard of internal affairs and by excessive Prussianism.

In forming the *Historische Zeitschrift* in 1859 in Munich, Sybel provided the model for many other periodicals. In 1875 Bismarck appointed him director of the Prussian archives, and he began a great series of publications. Some of his articles and addresses have been collected in *Vorträge und Abhandlungen* (1897), which

also contains a biography by C. Varrentrapp and a bibliography of Sybel's works. He died at Marburg on Aug. 1, 1895.

See G. P. Gooch, *History and Historians in the Nineteenth Century*, 2nd ed. (1952); H. Seier, "Die Staatsidee Heinrich von Sybels in den Wandlungen der Reichsgründungszeit 1862–71," *Historische Studien*, Heft 383 (1961).

**SYCAMORE**, the name applied to American species of plane trees (*Platanus*) and to a European species of maple (q.v.). The distinctive eastern sycamore (*P. occidentalis*), also known in certain localities as buttonwood or American plane, is probably the largest hardwood species in the eastern United States. Best development is attained on rich alluvial bottomlands, where it often reaches a height of 150 ft. and a diameter of 8 to 12 ft. It is occasionally found in pure groves, but is much more common as an occasional tree in association with other bottomland hardwood species such as river birch, red and silver maples, American elm, cottonwood, and willows. Sycamore features large, simple, shallowly three- to seven-palmately-lobed leaves, each with a long petiole or leafstalk swollen at the base and enclosing next year's bud. A pair of large leafy outgrowths or stipules at each node is another conspicuous feature.

The flowers are unisexual. Both sexes are borne in separate, solitary heads that appear in advance of the leaves. The fruit is a multiple head of obovoid achenes, each furnished at the base with a fringe of brown silken hairs.

Winter characters are also distinctive. The stout, brown, conspicuously zigzag twigs feature alternately disposed conical buds that are capped with a single scale and nearly surrounded by a leaf scar. Above each leaf scar is a prominent stipule scar which

(TOP) RUTHERFORD PLATT, (BOTTOM LEFT) J. HORACE MCFARLAND CO., (BOTTOM RIGHT) ROCHE SYCAMORE (PLATANUS OCCIDENTALIS) SHOWING (TOP) THE BROWN, OUTER LAYERS OF BARK WITH THE WHITE LAYERS BENEATH THEM, (BOTTOM LEFT) A LEAF AND (BOTTOM RIGHT) STAMINATE FLOWERS

encircles the twig. The bark on small branches is creamy white; that on larger limbs and the trunk (except near the base of large trees) is characterized by the annual exfoliation of the brown outer layers to expose the lighter yellowish to white layers immediately below.

The Arizona sycamore (*P. wrightii*) is one of the most abundant hardwoods of southwestern United States. The tree features deeply five- to seven-lobed leaves and the multiple heads of achenes are borne in racemose clusters of from two to four. The California sycamore, *P. racemoso*, a medium-sized tree of the coast ranges and lower Sierra Nevada Mountains of California, features three- to five-lobed leaves, and fruit in racemose clusters of two to seven.

(E. S. Hr.; X.)

**SYDENHAM, THOMAS** (1624–1689), English physician who revolutionized clinical medicine by basing his treatment of diseases on detailed observations of the patients rather than upon Galenic dogma or other speculative hypotheses, was born at Wyndford Eagle, Dorset, on Sept. 10, 1624. He entered Magdalen Hall, Oxford, in 1642 but left to serve the Parliamentary cause in the Civil War and did not graduate in medicine until 1648. He was elected a fellow of All Souls College the same year, but his studies were interrupted by the landing of Prince Charles in Scotland; in the subsequent campaign he was wounded while serving as a cavalry officer. He began to practise in Westminster, where he made the detailed study of London epidemics that formed the basis of his first book on the treatment of fevers (1666). Sydenham's book was greatly admired by John Locke, who (with John Mapletoft, professor of physic at Gresham College, London) helped him expand it into his major work, *Observationes medicae* (1676), which remained a standard medical textbook for two centuries.

Sydenham introduced tincture of laudanum (opium) into medical practice, was one of the first to use iron in the treatment of anemia, and helped popularize the use of quinine in the treatment of malaria. His most important therapeutic success was his management of smallpox by means of a cooling regimen quite contrary to the prevailing view. He was the first to describe scarlet fever and to explain the nature of hysteria and St. Vitus' dance (Sydenham's chorea). Among his clinical pupils were Thomas Dover, known for his powders, and Sir Hans Sloane, founder of the British Museum. Sydenham was a practical man with only a brief period of formal training, whereas most contemporary physicians were men of books. He was never elected to a fellowship of the Royal College of Physicians, as his views were regarded as unorthodox. He died in London on Dec. 29, 1689.

See J. F. Payne, *Thomas Sydenham* (1900); K. Dewhurst, *Dr. Thomas Sydenham* (1966).

(K. Dz.)

**SYDENHAM**, a residential area almost wholly in the borough of Lewisham (*q.v.*) but also extending into the Camberwell district of Southwark (*q.v.*), London, Eng. Its development dates from the reerection there (1854) of the Crystal Palace (burned down 1936); the first national recreation centre, built on the site with a main stadium and facilities for indoor sports, was opened in 1964. Sydenham Wells Park contains the site of medicinal springs popular in the 17th and 18th centuries. Former residents included the actress Sarah Siddons, the poet Thomas Campbell, and the colour printer George Baxter.

**SYDNEY**, the largest city of Australia and the capital, chief port, and industrial centre of the state of New South Wales, lies around the shores of Port Jackson in the southeastern part of the continent, on the eastern rim of a saucer-shaped depression known as the Cumberland or Sydney Basin. Pop. (1961 census): city, 172,202; metropolitan area, 2,183,388, an increase of 320,227 over the 1954 census. The Sydney coastline consists of a series of bold, scrub-covered headlands, alternating with crescent-shaped beaches. Other features of the coast include rock platforms, chains of shallow coastal lagoons, and sandpits and tombolos. The city has a temperate climate with a mean annual temperature of 17.6° C (64° F) and an annual average rainfall of 45 in. (1,140 mm.). More than 2,400 hours of sunshine are recorded annually; frosts are rare on the coast but may be severe inland. The prevailing winds are from the west and the northeast.

The excessive concentration of population around a few large cities is part of the overall population pattern of Australia. In the case of Sydney this concentration was due to the city's importance as the first settlement, and its consequent early development of harbour and storage facilities. As the main port Sydney naturally became the centre of government and also of the country's economic organization. Sydney proper lies on the southern shore of the harbour, and it is in that direction that the main commercial and industrial part of the city is to be found. Most of the city is hilly, the gradients, particularly in the harbourside suburbs, being short but steep. In the 1960s Sydney was growing rapidly both in area and population. Metropolitan Sydney covered an area of 671 sq.mi. (1,738 sq.km.). A notable feature of its continued outward sprawl was a shift of population, manufacturing, and retailing from the inner city to the suburbs.

Among Sydney's many fine buildings are the Town Hall (1889) on George Street, which houses the council chambers and a concert and assembly hall, and next to it St. Andrew's Cathedral (1888), whose original foundation stone was laid in 1819. Other notable churches are the Roman Catholic Cathedral—St. Mary's Basilica (1868)—and St. James' Church, the oldest church of any importance in the city. Opposite St. James' Church stands the Hyde Park Barracks, a fine example of Georgian architecture and a reminder of the city's origins, now used as a law court. The Old Mint Building (1811) is now also serving as a law court. The Australian Museum (1836) specializes in natural history, and the Public Library of New South Wales (1942) has a rich collection of books and manuscripts dealing with Australia, New Zealand, and the South Pacific. Other notable buildings and monuments include the State Parliament House (1811–17), the University of Sydney (1850), Captain Cook's Monument (1870), Macquarie Place, Vacluse House (c. 1802–03), and the Sydney Hospital. The Sydney Harbour Bridge (1932), one of the largest steel-arch bridges in the world, has a central span 1,650 ft. (503 m.) long, which carries one footpath, eight lanes for motor vehicles, one bicycle track, and two lines of rail tracks. In 1964 the Gladesville Bridge, said to be the longest concrete-arch span bridge in the world, was opened. During the 1960s Sydney's skyline was changing rapidly as older structures were demolished and tall new office buildings took their place. A notable addition to the city's architectural achievements was the Opera House, which was under construction in the mid-1960s.

The inner city contains more than 830 ac. (335 ha.) of parklands. The largest parks are Centennial Park on the eastern boundary; Moore Park; Hyde Park, the site of the Archibald Memorial Fountain and the Anzac Memorial; the Domain, which houses the National Art Gallery (1871); and the Botanic Gardens, with a large collection of plants. To the west of the Botanic Gardens stands Government House (1837–45), the residence of the governor of New South Wales, and at the northern entrance to the gardens is the State Conservatorium of Music, designed by Francis Greenway in 1819. On the northern side of the harbour is the Taronga Zoological Park and Aquarium. Koala Park at West Pennant Hills, about 20 mi. from the city centre, is a wildlife sanctuary and a biological research station. In the suburbs there are more than 14,000 ac. (5,700 ha.) of parkland and two national reserves: Kuring-gai Chase (40,000 ac. [16,000 ha.]) to the north and the Royal National Park (36,900 ac. [14,900 ha.]) to the south.

The city is a great recreation centre; facilities are available for most varieties of sports, particularly outdoor games, and Sydney's fine playing fields include the cricket ground and the sports ground, lying to the southeast of the city centre. The magnificent ocean beaches (notably Bondi Beach) provide opportunities for swimming and surfing. There are also several swimming pools, notably at Victoria Park and Prince Alfred Park, and the Olympic Pool in north Sydney has a spectator capacity of 4,000. Amateur and professional musical theatrical groups flourish, including the Elizabethan Theatre Trust, a state-sponsored body that presents important works in all branches of entertainment. Each spring, during the first week of October, Sydney celebrates the "Waratah Spring Festival" with carnivals, parades

open-air concerts, operas, and dancing, which culminate in a grand procession of floats to honour the festival queen. Sydney is particularly noted for its many Asian restaurants, serving Chinese, Indonesian, and Japanese food.

There are many public and private hospitals, including four large teaching hospitals. The City Council, which administers an area of 11 sq.mi., meets once every two weeks and maintains four standing committees: finance, works, health and recreations, and city planning and improvements. Transport is provided by government-owned buses, trains, and ferries, and a few privately operated buses and ferries. Sydney has 156 route miles of electrified track, and the Central Railway Station (1906) coordinates the movements of more than 1,150 trains daily. There are about 6,700 mi. (10,780 km.) of streets in the metropolitan area, and four major roads link Sydney with Melbourne, Brisbane, and Bathurst. In the 1960s work was proceeding on multi-lane roads to facilitate the flow of traffic between the city and suburbs. Kingsford Smith Airport can accommodate the latest jet aircraft. The Australian Broadcasting Commission maintains one television and two radio stations in Sydney, and there are three television stations and six radio stations operated commercially.

The port of Sydney (Port Jackson) averages about 1 mi. in width and has a total area of 21 sq.mi. (54 sq.km.). The shoreline extends for more than 150 mi. (240 km.), and its 12 mi. of docks and 200 wharves handle a large proportion of the trade of New South Wales. The main exports are wool, wheat and flour, sheepskins, and frozen and preserved meats. The chief import from overseas is liquid fuels; inter- and intrastate imports include coal, timber, and sugar. Sydney is the largest primary wool market in the world, and about two-thirds of all wool sold in New South Wales is shipped through the city. The port is also a shipbuilding and repair centre, and the Captain Cook Graving Dock (1945) can accommodate large vessels.

Sydney's industrial supremacy in Australia is due partly to its accessibility to raw materials. The city accounts for about half of the factory output of New South Wales, mainly consumer goods, but there are also important industries associated with sawmilling, shipbuilding, engineering, chemicals, agricultural and earth-moving equipment, electrical equipment, and oil refining. In the mid-1960s Sydney had more than 15,000 factories, employing about 350,000; annual value of production was nearly £A800,000,000.

Port Jackson was first sighted by Capt. James Cook in 1770, and on Jan. 20, 1788, Gov. Arthur Phillip chose "the head of the cove, near the run of fresh water" as the site of the first Australian settlement. Phillip had originally intended to call the new settlement "Albion," but instead the name "Sydney" (from Sydney Cove) came into general use. Sydney Cove had been named by Capt. Cook after his benefactor Thomas Townshend, 1st Viscount Sydney. The population during the town's first years was just over 1,000, mostly convicts who were unskilled in the trades needed to establish a permanent settlement. In 1833 the administration of the town was put in the hands of three magistrates, and in 1842 it received a municipal council and became a self-governing corporation. Between 1830 and 1840, as the influx of convicts dwindled, the commercial life of Sydney developed. Secondary industries, limited at first to brickmaking and sawmilling, developed slowly, for the state policy of free trade discouraged the establishment of local industries. After federation (1901) the free trade policy was rejected, and the closer association between the states led to a rapid upsurge of interstate trade. World Wars I and II, which occasioned great industrial expansion, firmly established Sydney's preeminence in production.

Until 1820 Sydney covered only about one square mile, but the discovery of gold in New South Wales and Victoria boosted the population enormously. It rose from 10,815 in 1828 to 95,789 in 1861, to 383,333 in 1891, and to 1,235,267 in 1933. In 1901 Sydney was formally elevated to the rank of a city, the use of the title of lord mayor being created the following year. In 1948 the Sydney Corporation Act was repealed, and the city became subject to the control of the Department of Local Government, while still maintaining autonomy in government through its permanent administrative staff and elective council.

**SYDNEY**, a city of Nova Scotia, Can., is the commercial and industrial centre of Cape Breton County. Founded by Joseph Frederick Wallat des Barres in 1783 as a haven for United Empire Loyalists, and named after the colonial secretary, it was the capital of Cape Breton Island until 1820 when the island was united with Nova Scotia. The population was increased during the early 19th century by the immigration of Scottish Highlanders. Sydney is a divisional terminus of the Canadian National Railways, and on the south arm of its harbour are excellent facilities for oceangoing vessels. It is the centre of a large coal-mining district with an urban population exceeding 100,000. Glace Bay (q.v.), 14 mi. (23 km.) E, New Waterford, 14 mi. NE, and Sydney Mines on the north side of the harbour are the major mining centres. North Sydney, on the northwest arm of the harbour, is the terminus of the ferry service to Port aux Basques, Nfld. Xavier Junior College (1952), an affiliate of St. Francis Xavier University, Antigonish, is located in Sydney. Across the south arm of the harbour is the Point Edward Naval Base. Pop. (1961) 33,617. (C. W. Rd.)

**SYENITE**, in petrology, the group name for a class of plutonic rocks composed essentially of an alkali feldspar and a ferromagnesian mineral. A special group of alkali syenites is characterized by the presence of a feldspathoid mineral (nephelite, or nepheline, leucite, analcite or sodalite).

The name was first used by Pliny for the rock occurring at Syene (Aswan) on the Nile River in Upper Egypt. This rock, extensively worked in ancient times for monumental structures, is a hornblende-granite with abundant quartz. A. G. Werner subsequently adopted the name for the class of rocks defined above, of which the type example is the hornblende-syenite of the Plauen'scher Grund, near Dresden, Ger. As essential constituents there occur soda orthoclase and green hornblende with subordinate amounts of oligoclase feldspar.

The texture of syenites is granular like that of the granites. Mineralogically these rocks differ from granites only by the absence or scarcity of quartz. The alkali feldspars include orthoclase, perthite, or albite, more rarely microcline, while the ferromagnesian mineral may be biotite, hornblende, or pyroxene. In the alkali syenites, the amphiboles or pyroxenes are frequently soda-bearing varieties. The more normal syenites are divisible into augite-, hornblende-, and biotite-syenites according to their prevalent dark-coloured mineral, but syenites are also divisible, as in the case of granites, into potash and soda syenites, according to the type of alkali feldspar. The accessory constituents include sphene, apatite, zircon, magnetite, and pyrites. Syenites are by no means common and are not of equal importance with granites and diorites from a geological standpoint.

Among the potash syenites are classed the original hornblende-syenite (Plauen) and the hornblende-syenite of Biella, Piedmont, Italy, of which analyses are given below.

The rocks known as nordmarkite and pulaskite are classed among the soda syenites. Nordmarkite originally described from the Oslo region (Norway) is built up of pink microperthite and subordinate aegirite and arfvedsonite together with some quartz, while the pulaskite syenites, first described from the Fourche Mountains, Ark., consist of soda orthoclase and alkali hornblende together with some biotite. Rocks transitional between syenites and diorites are known as monzonites (q.v.).

The following analyses show the chemical composition of a few of the principal types of syenite. They are characterized by a

	SiO <sub>2</sub>	Al <sub>2</sub> O <sub>3</sub>	Fe <sub>2</sub> O <sub>3</sub>	FeO	MgO	CaO	Na <sub>2</sub> O	K <sub>2</sub> O
1	60.52	16.65	2.97	2.15	2.32	4.73	4.43	4.39
2	59.37	17.92	6.77	2.02	1.83	4.16	1.24	6.68
3	59.88	17.87	2.67	1.50	1.04	2.01	7.96	5.69
4	58.97	16.33	2.72	4.14	2.72	4.29	4.10	4.54

1. Hornblende-syenite, Plauen'scher Grund, Dresden, Ger.
2. Hornblende-syenite, Biella, Piedmont, Italy.
3. Nordmarkite, Oslo, Nor.
4. Syenite (mean of 12 analyses).

moderate amount of silica, relatively high alkalis, and alumina; while lime and magnesia are more variable but never in great amount.

(C. E. T.)

**SYKES, SIR MARK**, 6TH BARONET (1879–1919), British traveler and politician, who represented the British government in the so-called Sykes-Picot negotiations (1915–16) between Great Britain and France, was born in London on March 16, 1879, the only son of Sir Tatton Sykes, 5th baronet. He was educated at Beaumont College and abroad, and at Jesus College, Cambridge. After serving in the South African War (1899–1902), he was secretary (1904–05) to George Wyndham, chief secretary in Ireland, and from 1904 to 1913 traveled extensively in Asiatic Turkey. He published vivid and valuable accounts of his travels in *Through Five Turkish Provinces* (1900), *Dar-ul-Islam* (1904), *Five Mansions of the House of Othman* (1909), and *The Caliph's Last Heritage* (1915). He was elected as member of Parliament for Central Hull, Yorkshire, in 1911 and succeeded as 6th baronet in 1913.

In 1914, just before the outbreak of World War I, he raised a battalion of the Yorkshire Regiment but did not accompany it to France; instead he was used on brief diplomatic missions in the Balkans and Turkey. Between 1915 and 1916 he was the chief British representative in the Sykes-Picot negotiations between France (represented by F. Georges Picot) and Great Britain to settle a basis of agreement on their claims, which were to be made good after the war, to those territories they hoped to detach from the Ottoman Empire. The resulting agreement, signed in May 1916 by Britain, France, and Russia (which was party to the talks), provided for the division of the area then covered by Syria and Iraq into spheres of French and British influence, and even direct administration, leaving Palestine to be subject to international control. These arrangements, which were secret, were publicized by the revolutionary Russian government in 1917; they were subsequently condemned by the Arabs and their supporters as improper, and inconsistent with promises of postwar independence made to the Arabs. The agreement, which Sykes later regretted, and in which his personal part is uncertain, never came into force.

Sykes remained active in Near Eastern missions for the Foreign Office between 1916 and 1918, and he keenly supported the movement for Arab freedom with which the agreement bearing his name had dealt so harshly. He revisited Syria in 1918, working (largely in vain) to smooth Anglo-French relations. He died suddenly in Paris on Feb. 16, 1919.

**BIBLIOGRAPHY.**—S. Leslie, *Mark Sykes: His Life and Letters* (1923); for the Sykes-Picot agreement see G. Antonius, *The Arab Awakening* (1938); S. H. Longrigg, *Syria and Lebanon Under French Mandate* (1958).

(S. H. Lo.)

**SYLHET**, a town in the Chittagong division of East Pakistan and the headquarters of the district of the same name, lies on the right bank of the Surma River, 123 mi. (198 km.) NE of Dacca. Pop. (1961) 37,740. The town has three degree colleges affiliated to Dacca University. It is well known for its cane industry, and there are many tea factories. It has long been a centre of Islamic culture, and many holy men are buried there.

**SYLHET DISTRICT** has an area of 4,785 sq.mi. (12,393 sq.km.). Pop. (1961) 3,489,589. It comprises five-sixths of the former British Indian district of the same name, which formed part of Assam until the partition of India in 1947. It consists of the lower valley of the Surma River and is for the most part a uniform, well-cultivated plain, broken only by scattered clusters of sandy hillocks and intersected by a network of rivers and drainage canals. The low-lying swamps are a special feature of the district. Rainfall is heavy, reaching an annual average of 159 in. (4,040 mm.), of which more than 100 in. (2,540 mm.) fall between June and October. Rice is the chief crop. Tea cultivation flourishes in the southeastern hills. Lime is extensively quarried; other industries are boat building and the manufacture of fine reed mats, buttons from freshwater shells, ironwork inlaid with brass, and perfume. Search for oil in East Pakistan resulted in the discovery in 1955 of a gas field at Haripur, near Sylhet, that has estimated reserves of 280,000,000,000 cu.ft. More gas fields

were subsequently discovered at Chhatak (1959), Rashidpur (1960), Kailas Tila (1962), and Habiganj (1963). (K. S. Ad.)

**SYLLOGISM**, a two-premiss argument of any of several rather simple types distinguished by Aristotle or by those who followed in his tradition. Syllogisms are usually classified as categorical, hypothetical or disjunctive, depending upon the nature of their premisses. A categorical syllogism consists of three categorical statements (i.e., statements of the forms "All *S* is *P*," "No *S* is *P*," "Some *S* is *P*," or "Some *S* is not *P*") which contain a total of at most three terms among them, each term occurring in at least two of the statements. A typical example would be:

No matadors are pirates.

Some Spaniards are matadors.

Therefore, some Spaniards are not pirates.

which is of the form (or mood) called *Ferio*:

No *M* is *P*.

Some *S* is *M*.

Therefore, some *S* is not *P*.

In the hypothetical syllogism one or both of the premisses are hypothetical in form (i.e., have the form "If *p* then *q*"). Thus:

If *p* then *q*.

If *q* then *r*.

Therefore, if *p* then *r*.

is one of the valid moods of the hypothetical syllogism. Similarly, a syllogism is disjunctive if one of its premisses is a disjunction. For example, every argument of the form:

Either *p* or *q*.

Not *p*.

Therefore, *q*.

is a valid disjunctive syllogism.

The term *syllogismos* ("syllogism") was used by Plato and occasionally by Aristotle simply with the sense of "argument." To this effect the latter gave his famous definition: "A syllogism is a discourse in which, certain things being posited, something else follows from them by necessity." In most cases, however, Aristotle used the term technically for the categorical syllogism. Later the meaning was extended by the Peripatetics to include hypothetical and disjunctive syllogisms. In Stoic usage the adjective *syllogisticos* ("syllogistic") was applied to any arguments of their five basic types.

See LOGIC and LOGIC, HISTORY OF.

(B. Ms.)

**SYLT**, the largest and northernmost North Sea island of the German North Frisian group. Area 36 sq.mi. (93 sq.km.). Pop. (1961) 17,582. In the central section of the smooth west coast, cliffs of soft red sandstone rise to 135 ft. (41 m.). In the south the island is often only half a mile wide, but in the centre a beak-like peninsula extends 7 mi. (11 km.) E toward the Schleswig-Holstein coast. Road and rail connection with the mainland is carried by the Hindenburgdamm (causeway) for 7 mi. across the shallow tidal flats. There are a few small farmers, with dairy cattle and sheep, and scattered villages, such as Keitum; the principal settlement is the holiday resort of Westerland.

(Ha. T.)

**SYLVESTER, JAMES JOSEPH** (1814–1897), English mathematician who with his contemporary, Arthur Cayley (q.v.) founded the theory of algebraic invariants, was born in London on Sept. 3, 1814. In 1831 he entered St. John's college, Cambridge, where he gained high honours. In 1838 he was appointed professor of natural philosophy at University college, London. In 1841 he accepted the professorship of mathematics at the University of Virginia, but resigned after several months. Sylvester returned to London in 1845 where he obtained employment in actuarial work and took private pupils, one of whom was Florence Nightingale. In 1846 he entered the Inner Temple and in 1850 was called to the bar. About this time Sylvester and Cayley began an enthusiastic and profitable mathematical partnership. From 1855 to 1870 he was professor of mathematics at the Royal Military academy, Woolwich. It was not until 1876 that Sylvester got the first opportunity of his life commensurate with his talents, when he was appointed professor of mathematics at Johns Hopkins university, Baltimore, Md. In 1883 he returned to England to succeed Henry J. S. Smith as professor of geometry at Oxford. He died in London, March 15, 1897.

Sylvester was primarily an algebraist. With Cayley, he created the theory of algebraic forms. In the theory of numbers he did brilliant work, particularly in partitions and diophantine analysis. He worked by inspiration, and frequently it is difficult to detect a proof in what he confidently asserted. All his work is characterized by powerful imagination and inventiveness. While at Johns Hopkins, Sylvester founded (1878) the *American Journal of Mathematics*. See also **MATRIX**.

See E. T. Bell, *Men of Mathematics* (1937), "Invariant Twins, Cayley and Sylvester," in *The World of Mathematics*, ed. by J. R. Newman, vol. 1 (1956, 1962). (E. T. B.; X.)

**SYLVESTER, JOSUAH** (1563–1618), English poet-translator, best known as a translator of a popular biblical epic, was born in Kent and died on Sept. 28, 1618, at Middelburg in the Low Countries, where as secretary to the Merchant Adventurers he wound up a varied career. His chief production, the *Divine Weeks and Works*, translated from the French Protestant poet Guillaume du Bartas (1544–90), appeared in sections in 1592 and complete in 1608. This epic on the Creation, the fall of man, and other early parts of Genesis had high prestige in Europe generally and, in Sylvester's translation, was extremely popular in England in the first half of the 17th century. Its appeal was in its biblical matter, its reassuringly orthodox treatment of religion, nature as God's handiwork, science and cosmology, and in the grandiose, picturesque vigour of the writing—a quality only heightened in Sylvester's frequent extravagance of phrase, which Dryden, a youthful admirer, came to regard as "abominable fustian." Sylvester had some small influence on Milton and also had a share in the early development of the heroic couplet and the "poetic diction" which the Augustans were to refine.

The *Complete Works of Josuah Sylvester* were edited by A. B. Grosart in 2 vol. (1880).

(D. BH.)

**SYLVITE**, a mineral consisting of potassium chloride and the chief commercial source of potassium compounds, was first observed in 1823 as an incrustation on Vesuvius lava. Well-formed crystals were subsequently found in the salt deposits of Stassfurt, Ger., and Kaluszyn, Pol. It also occurs in the southern Harz region of Germany, in the nitrate deposits of Chile and Peru, and in the Permian salt basin of southeastern New Mexico and adjoining parts of Texas. Sylvite crystallizes in the cubic system with the form of cubes and cubo-octahedra and possesses perfect cleavages parallel to the faces of the cube. The composition is KCl and the crystal structure is similar to that of rock salt, NaCl. Crystals are colourless (sometimes bright blue) and transparent; the hardness is 2; specific gravity 1.99. Like salt, it is highly transparent to heat waves. The name sylvite is from the old pharmaceutical name, *sal digestivus sylvii*. (CL. F.; X.)

**SYLVIVS, FRANCISCUS** (FRANZ DE LE BOË, or DU BOIS) (1614–1672), German physician and anatomist, called the true founder of the iatrochemical school (see **IATROCHEMISTRY**), was born in Hanau on March 15, 1614. He studied at various universities, acquired a degree from Basel and became professor at the University of Leiden (1658), where his enthusiasm and original ideas attracted numerous students. An instance of pedagogical novelty, although not originality, was Sylvius' introduction of ward instruction in medical education.

Sylvius based his medical system upon such then recent developments in anatomy and physiology as the circulation of the blood and the recognition of the lymphatics, although still within the general framework of Galen's humoral physiology. At the same time, like his predecessor, J. B. van Helmont (*q.v.*), but omitting the mystical element so strong in the latter, he emphasized the chemical aspects of physiology. His study of salts led him to the belief that they were the result of the interaction of

acids and bases, and he recognized their existence in living matter in his *Praxeos medicae idea nova* (1671–74).

According to Sylvius, digestion is a process of fermentation in which the saliva and pancreatic juice play the chief roles, the former determining digestion in the stomach and the latter directing the course of the digested food into blood or feces. The most important processes of normal and pathological life take place in the blood, and diseases are explained and treated chemically, the indications for treatment being based upon the presumed relationship between disease and drug.

In other aspects of medicine Sylvius distinguished between conglomerate and conglobate glands, and it is his name that is associated with the Sylvian aqueduct and Sylvian fissure, described in his *De spirituum animalium in cerebro cerebelloque confectione* (1660), although these structures appear to have been noted earlier by others. He also made some contribution to pediatrics through his posthumous *De morbis infantium* (1674), which, translated into English in 1682, gained favour perhaps more through its author's academic stature than through any singular importance of the contents.

Sylvius died in Leiden on Nov. 15, 1672.

(C. D. O'M.)

**SYMBIOSIS** is the general term for the partnerships of dissimilar organisms; it denotes simply the living together of different kinds of organisms. Three major types of symbiosis may be recognized: (1) commensalism, in which food or space may be shared without evident benefit or harm to either organism or in which the benefit relation is one-sided, but without harm to the host; (2) mutualism, in which both host and guest (or the two partners) are obviously or apparently benefited; and (3) parasitism, in which the host is subject to varying degrees of injury while the parasite benefits. The term symbiosis has been widely used in the restricted sense of mutualism. The broader definition corresponds both to the original definition of symbiosis by Heinrich de Bary (1879) and to modern usage. Because of the great importance of parasitism to human life and economy, this subject is dealt with separately (see **PARASITOLOGY**).

**Commensalism.**—Pierre van Beneden (1876) referred to a commensal as an organism that "requires from his neighbour a simple place on board his vessel, and does not partake of his provisions. The messmate does not live at the expense of his host; all he desires is a home or his friend's superfluities." The arrangement represents a level of relationship a degree removed from that in aggregations of animals about a common food supply.

The commensal relation is often between individual larger host and individual smaller guest; the host organism is unmodified, whereas the commensal guest may show great structural adaptation consonant with its habits, as in the remoras (*q.v.*) that ride attached to sharks and other fishes, or no modification other than the habit of dependence on its host. The main types of dependence shown in commensalism are for shelter, support, locomotion (*i.e.*, distribution and spread), and food supply. These may be single or variously combined. Some of the more familiar household insects associated with man illustrate several of these relations—the house cricket, the common cockroach, etc. Only when the host-guest relation is recognizably specific, a particular guest species being regularly commensal with a particular host species, is commensalism sharply defined. The shelter relation is seen in the inhabitants of the tubes of marine worms, in the *Nomeus* fishes among the tentacles under Portuguese men-of-war, in the ferasfer fishes that occupy the cloaca of sea cucumbers, or in the insect inhabitants of field mouse nests. The support relation may involve plants sessile upon animals, as algae on turtle shell, or animals on plants, as bryozoans and hydroids on floating sargassum weed. Locomotion and food supply are combined in the remoras. Food supply is the main factor in the host of bacteria and protozoa that inhabit the gut of larger animals without apparent contribution to the digestive process of the host.

The opposite of commensalism is amensalism, in which one

#### SYMBIOTIC RELATIONSHIPS

(Left) Commensalism (or in some cases mutualism) between a hermit crab, which has occupied a snail shell, and a sea anemone. (Above) Mutualism of white cattle egrets and elephants. (Right) Parasitism of wasp cocoons on a moth larva

population (the amensal) adversely affects another population. Man takes advantage of this type of relationship between colonies of the mold *Penicillium* and certain types of bacteria (see ANTI-BIOTICS).

**Mutualism.**—Relationships in which there are benefits to both partners and in which both may be radically modified in adjustment to the mutualistic relation are widespread. They present diverse aspects. Mutualism may exist between plant and plant, between plant and animal and between animal and animal. The adjustments are both operational and evolutionary, and the mutualistic relation is one of the major types of co-operation in nature.

**Plant and Plant.**—In apparently mutualistic relations between plant and plant, the degree of benefit to one or the other partner may be obscure. One of the best known of such partnerships is that between fungi and algae to form lichens (*q.v.*), the discovery of which led to the coining of the term symbiosis. The support and protection supplied by the fungus, combined with the carbohydrate synthesis by the alga, makes possible the invasion of inhospitable rock surfaces and other adverse environments by lichens.

The relation of certain fungi with the roots of higher plants (mycorrhiza; *q.v.*) is extremely widespread and not, indeed, confined to the higher plants. Fungus mycelium (of various species) may form an enclosing feltlike mat around the roots of trees and other woody plants. In this case the benefit to the higher plant appears to lie in improved absorption of the food-bearing solution at the root surface. Even more intimate relations appear in the mycorrhiza of orchids, in which the fungus mycelium may be essential to normal germination and development. The fungus mat may be entirely external, or the fungus may send filaments throughout the host plant. In the latter case the filaments of mycelium on the roots replace the normal root hairs.

The combination of nitrogen-fixing bacteria with leguminous plants recalls the mycorrhizal relation in the obscurity of benefit to the bacteria, though in the legumes gall-like root nodules harbour the bacteria. The existence of the fixed association is the presumptive evidence of mutual benefit.

**Plant and Animal.**—The combination of green algae with various simple animals is made conspicuous by the resultant colouring of the animals. Various single-celled green algae, zoochlorellae, together with superficially similar yellow or brown flagellates, zooxanthellae, are regularly associated with protozoa, sponges,

coelenterates, and flatworms. They are regularly present in the polyps of reef corals. In its life cycle the free-living marine flatworm *Convoluta roscoffensis* begins existence entirely free from zoochlorellae, acquires a dense intracellular population of the algae as it develops, whereupon it ceases active feeding, and finally loses the algae during senescence. In the similar association of algae with the fresh-water *Chlorohydra viridissima* the supply of oxygen and carbohydrate food to the host animal and of carbon dioxide and nitrogenous food to the plant was experimentally examined and largely substantiated. In *Chlorohydra*, the transmission of the zoochlorellae to the egg cell takes place directly.

The habit of growing various fungi for food developed independently among beetles, termites, and ants. The fungi grown by various species of beetles of the families Ipididae and Platypodidae in burrows in tree

trunks appear to be species-specific. The leaf-cutting ants commonly extend their destructive activities to horticultural plants and have thus been the focus of much study. The fungus-growing termites of the old world obviously developed this habit independently of ants and beetles. For all these insect gardeners some means of transmitting the fungus to a new nest is essential; in many forms remarkable special apparatus exists for this purpose.

An important mutualistic relation exists between larger animals like many ruminants (cow, goat, sheep, camel, etc.) and a series of bacteria that inhabit their alimentary tracts, for the bacteria aid in the digestion of cellulose or other food materials and synthesize certain vitamins. Enormous numbers of such bacteria may be harboured in special intestinal pouches (caeca) or elaborate divisions of the stomach.

Among the most interesting of the mutualistic plant-animal symbioses are those between insects and certain bacteria and fungi. In some instances the microorganisms (or symbiotes) live freely in the lumen of the alimentary tracts or in the associated caeca of their insect hosts. In other instances the symbiotes live within the tissue cells of the insect. In both instances the microorganisms appear to be highly specific and are transmitted from generation to generation by rather complicated mechanisms, usually via the eggs of the insect. In most instances the beneficial role played by the symbiotes is unknown, or only assumed; however, in many cases it has been shown that the insect cannot survive without the symbiotes and that the latter may produce certain essential vitamins or hormonelike substances. In aphids, for example, the symbiotes are believed by some to fix atmospheric nitrogen.

The insect-symbiote relationship is an intimate one since usually every individual of an insect species harbours the microorganism. The intracellular symbiotes live in cells called mycetocytes, which are frequently grouped into an organ or structure known as a mycetome. Some of the extracellular symbiotes occurring in the alimentary tracts of insects are known to take an active part in the digestive processes of the host (such as the bacteria found in the "fermentation pouches" of larvae of lamellicorn beetles). Certain bacteria are found in large numbers in the "gastric caeca" of higher Hemiptera. The arthropod hosts of the intracellular symbiotes occur in most of the principal orders of insects and numerous families of ticks and mites. Insects of both medical and agricultural importance are concerned, including such groups

as cockroaches, lice, bedbugs, reduviid bugs, aphids, scale insects, beetles, and ants.

A vast series of plant-animal mutual benefit associations is supplied by the phenomenon of insect fertilization of flowers. These range from the most casual visitation of a flower by a wide variety of insects, in which there may be little or no modification for the accomplishment of pollination, to the most strict relation of a single species of flower with a single species of insect, in which both are modified for their mutual relations, as for example between the yucca plant and the yucca moth. Elaborate and complex flower mechanisms, in which exactness of fit of flower parts to a specific insect, and correspondingly elaborate insect structures that function solely in cross-fertilization of the appropriate plant, have been demonstrated (see *POLLINATION*).

*Animal and Animal.*—The mutualistic relations between animal and animal may begin at the simple level of the association of birds with large herbivorous mammals, as of the North American cowbird and the African tickbirds with domestic cattle, and the little white cattle egret, which associates itself with elephants and rhinoceroses as well as with domestic cattle throughout its range from North Africa to the East Indies.

The upsurge in skin diving led to the discovery that many marine organisms specialize in removing parasites from fishes. Smaller fishes and shrimps live by cleaning larger fishes, and the hosts thereby benefit; this mutualistic process has been termed cleaning symbiosis.

A more intimate level of such mutualism between diverse types of animals is found among marine animals. Hermit crabs of various species may beset their snail-shell house with hydroids (e.g., *Eupagurus constans* with *Hydractinia sodalis*) or with sea anemones (*Eupagurus prideauxi* with *Adamsia* species). Other crabs may regularly bear small sea anemones in their claws. Still others regularly have their shells grown over with various species of sponges. The advantage to the sessile animals is evidently that of locomotion, the advantage to the crustacean lies in protection or camouflage. Although some of these associations appear to be merely commensalistic, others approach mutualism, as shown especially by the hydroid *Hydractinia sodalis*, in which the basal layer that bears the polyps grows forward from the mouth of the snail shell inhabited by the hermit crab, thus making it unnecessary for the crab to undergo the hazard of changing its snail-shell house as it grows. The sea anemone *Adamsia* performs the same apparently essential function for its host. In addition many of these hydroids and sea anemones have long nematocyst-bearing filaments that serve as protection for themselves as well as for their hosts.

The cellulose-digesting mutualism of vertebrates and insects with bacteria is paralleled at the animal-animal level by a series of protozoa that accompany the bacteria in the alimentary tracts of various animals, ranging from harmless commensals to effective agents for cellulose digestion and to parasitism. The most sharply defined relation of this kind is represented by the association of primitive termites with characteristic and highly modified protozoans. It has been shown that the protozoans are characteristic of the species of termite inhabited.

The fungus gardens of the ants are matched by the relation between ants and aphids, and certain other insects. The ants give elaborate care to the aphids from which they obtain the secreted honeydew, protecting the aphids from adverse weather and moving them from one plant to another. Ants also protect aphids from certain of their natural enemies.

The series of nest inhabitants found regularly in the nests of both termites and ants exhibit the range from commensalism to a pseudomutualism of an elaborate and special form. Various families of insects, especially beetles, are associated with greatly modified ant and termite guests not found elsewhere. These forms produce special secretions, so much valued by the hosts that they treat them as normal and even favoured nest inhabitants.

The interrelations of commensalism, mutualism, and parasitism are extremely complex. It is evident that parasitism may evolve from either external or internal commensalism and that mutualism may commonly develop from the various types of com-

mensalism. In the opposite direction, it is quite possible that mutualism may arise by complete adjustment of host and guest from an originally parasitic relation.

**SYMBOLIC LOGIC**, logic in which special signs or symbols are used for notation of the forms of sentences expressing propositions. See *LOGIC*; and *LOGIC, HISTORY OF: Modern Logic*.

**SYMBOLISTS, THE**, a group of French writers who considered themselves disciples of Stéphane Mallarmé and Paul Verlaine and who sought, between about 1885 and 1895, to react against Parnassian poetry (see *PARNASSIANS*), the Realist theatre, and the Naturalist novel in order to express by way of symbol the mystery of existence. Although writing in French, not all the Symbolists were of French birth: Jules Laforgue, Gustave Kahn, René Ghil, Albert Samain, and Henri de Régnier were French or of French parentage, but Albert Mockel, Maurice Maeterlinck, Georges Rodenbach, and Émile Verhaeren were Belgian; Jean Moréas was of Greek origin, and Francis Vielé-Griffin and Stuart Merrill were American by birth, although all three came to France in early youth.

The Symbolist manifesto was published by Moréas in *Le Figaro* on Sept. 18, 1886. There was no uniform doctrine, however, different theories being expounded in such reviews as *Lutèce* (1883), *La Revue wagnérienne* (1885), *La Vogue* (1886), *La Plume* (1889), and *Le Mercure de France* (1890). Verhaeren attempted a definition in *L'Art moderne* of April 24, 1887, but just how many dissident groups remained (Instrumentalists, Melodists, Vers-librists, etc.) is evident from Jules Huret's *Enquête sur l'évolution littéraire* (1891). Mallarmé's *Divagations* (1897), which incorporates ideas propounded at his Tuesday receptions attended by the younger generation, remains the most valuable statement of Symbolist aesthetics, just as his *L'Après-midi d'un faune* (1876) was the first masterpiece of Symbolist poetry, and also the greatest. Whatever their differences, the Symbolists were unanimous in acclaiming their precursor to be Baudelaire, whose theory of the *correspondances* between the senses they found applied by Arthur Rimbaud in his "Sonnet des Voyelles." They were also influenced by the poetics of Edgar Allan Poe and by the ideal to which Wagner aspired, of a synthesis of the arts. Schopenhauer's formula, "the world is my idea," and Eduard von Hartmann's theory of the unconscious likewise contributed to the Symbolist aesthetics.

All Symbolists retained the Parnassian concept of "art for art's sake" with its insistence on technical perfection, but they repudiated the descriptive imagery of the Parnassians. They aimed at an art more suggestive and more subtle, at poetic images projecting what Régnier called the poet's "inner dream." Poetry at this period assumed almost the status of a religion and, like religion, required to be shrouded in mystery. It was to have its own language, entirely distinct from that of prose. To this end, Mallarmé proceeded to create a "pure language" by using words in their etymological meaning, and to envelop poetry in a well-calculated hermetism. Interest in neologisms, already evident in Rimbaud and Laforgue, and in phonic values, inspired Ghil's *Traité du verbe* (1886) with its *Avant-dire* by Mallarmé. In order to "express the inexpressible," poets were urged in Teodor de Wyzewa's *L'Art wagnérien* (1886) to turn for guidance to the most suggestive of the arts, music, which by its nature reached deeper levels of the unconscious. They aimed at using in literature certain musical techniques of Wagnerian drama, the *Leitmotiv* (q.v.) for instance. Mallarmé and Verlaine considered the musical element in poetry to be fundamental, but Mallarmé remained more traditional in his versification and made abundant use of the *rime riche* advocated by Théodore de Banville, while Verlaine and his disciples experimented daringly with assonance, *vers impairs*, and metrical patterns borrowed from folk songs. To escape metrical rigidity, many writers, following the precedent of Mallarmé and Rimbaud, practised the prose poem; Laforgue, Vielé-Griffin,

and Verhaeren, stimulated by the example of Walt Whitman, wrote free verse (*q.v.*), the chief exponent of which was Kahn in the preface to the second edition of his *Les Palais nomades* (1887). With this innovation, which Mallarmé deplored, many Symbolists claimed that French poetry had at last been freed from the bonds of classical prosody.

Mallarmé and Villiers de l'Isle-Adam envisaged the theatre as a temple for the enactment of a supreme ceremony. A. Antoine's productions of Ibsen revealed the possibilities of symbol on the stage; what the critic Édouard Schuré called "a theatre of the soul" was expressed in the productions of Paul Fort at his Théâtre d'Art (1890) and A. M. Lugné-Poe at his Théâtre de l'Oeuvre (1893). The most memorable examples of the Symbolist theatre, apart from Villiers de l'Isle-Adam's *Axel* (published 1890; produced 1894), were Maeterlinck's *Pelléas et Mélisande* (1893), with its dreamlike atmosphere, which was set to music by Debussy (1902); and Alfred Jarry's highly satirical *Ubu Roi* (1896), which caused an uproar. The Symbolist contribution to fiction was less significant, but J.-K. Huysmans' *À Rebours* (1884) drew public attention to Mallarmé, and Édouard Dujardin's *Les Lauriers sont coupés* (1888) influenced James Joyce. The Symbolists left their mark on world literature. Paul Valéry and Paul Claudel in France, Stefan George and Rainer Maria Rilke in Germany, Aleksandr Blok in Russia, and W. B. Yeats inherited from them an aristocratic conception of their art and a certain hermeticism.

**SYMMACHUS, SAINT** (d. 514), pope from 498 to 514, a native of Sardinia and apparently a convert from paganism, was in deacon's orders when he was elected as successor to Anastasius II and promptly consecrated, in the Lateran, on Nov. 22, 498. The election, however, was not unanimous: another candidate, Laurentius, having the support of a strong Byzantine party, was also consecrated, in Sta. Maria Maggiore, on the same day. A decision was obtained in favour of Symmachus from the Gothic (and Arian) king Theodoric; but peace was not established until 505 or 506, when Theodoric ordered the Laurentian party to surrender the churches of which they had taken possession. The schism was not fully healed till the reign of Hormisdas, Symmachus' successor. An important incident in the protracted controversy was the decision of the "Palmary Synod"—the fourth session of a council called by Theodoric at Rome in 502 to deal with the charges brought against Symmachus by the Laurentians—in favour of Symmachus; the bishops declared that there was no precedent for the pope's being judged by other bishops. The dispute gave rise to a body of spurious literature that was drawn on by later exponents of the doctrine *quod prima sedes non judicatur a quoquam* (i.e., that no one can pass judgment on the pope).

Symmachus was a strong supporter of orthodoxy in the Acacian schism, and he burned the Manichaeans' books and expelled them from Rome. He was a friend of the poor and of the Catholics of Africa who were enduring persecution by the Arians. He erected or restored a number of Roman churches, an inscription on one of which (referring to the end of the Laurentian troubles) reads: "The biting of the wolves has ceased." Symmachus died on July 19, 514; the anniversary is his feast day. See also PAPACY.

**SYMMACHUS, QUINTUS AURELIUS** (c. A.D. 345–402), Roman consul in 391 and a distinguished author, was the son of a consular family of great distinction and wealth. His oratory brought him an illustrious official career culminating in the proconsulship of Africa in 373, the city prefecture at Rome in 384, and the consulship. When the emperor Gratian, influenced by the Christian bishop of Milan, St. Ambrose, ordered the statue of Victory to be removed from the Senate house at Rome in 382, Symmachus, who was an earnest pagan, was appointed by the Senate to go to Milan to plead with the emperor to cancel this antipagan measure; but the mission was a failure. After Gratian's

murder in 383, Symmachus renewed his plea to Valentinian II to revoke Gratian's antipagan orders; but, largely owing to the opposition of St. Ambrose, he was again unsuccessful. Symmachus' oration *De ara Victoriae* was considered so brilliant that even after 19 years the poet Prudentius found it necessary to write a reply to it. The increasingly Christian character of Valentinian's court caused Symmachus to lose much of his influence; but when Magnus Maximus (*q.v.*) drove Valentinian from Italy in 387, Symmachus, who was regarded as the leader of the Senate, was appointed to offer the new emperor the Senate's congratulations on his elevation. When Theodosius I reconquered Italy, Symmachus was forgiven and appointed consul for 391. Under the pagan rule of Eugenius and Arbogast in 392–394 (see THEODOSIUS), he apparently regained some of his influence and survived under Honorius until 402. He owned three houses at Rome and no fewer than 15 estates in Italy, Sicily, and Mauretania.

Symmachus' extant works, of which the most important are the ten books of his *Letters*, have been edited by O. Seeck, in *Monumenta Germaniae Historica*, vol. vi, part 1 (1883). (E. A. T.)

**SYMONDS, JOHN ADDINGTON** (1840–1893), English man of letters, most widely known in his own day as the historian of the Italian Renaissance and now recognized as a pioneer in the study of homosexuality. Born at Bristol on Oct. 5, 1840, and educated at Harrow and Oxford, where in 1862 he was elected a fellow of Magdalen College, he developed early symptoms of pulmonary disease and after many journeys in search of health finally settled at Davos Platz in Switzerland, where most of his work was done, though with frequent journeys to Italy. In poetry particularly, Symonds found relief from grave emotional problems. The study of his own abnormal temperament resulted in *A Problem in Greek Ethics* (privately printed, 1883), an enquiry into sexual inversion, and this led to collaboration with Havelock Ellis (*q.v.*). Symonds' most elaborate work, *Renaissance in Italy* (7 vol. 1875–86), is rather a series of extended essays than a systematic history. Fluent and picturesque, with the prejudices of its period, it was deeply indebted to such continental interpreters of the Renaissance as Jacob Burckhardt and Francesco De Sanctis. It was long useful and widely read, but it has been superseded.

Symonds also translated the sonnets of Michelangelo and Campanella (1878), and Cellini's autobiography (2 vol. 1888), and wrote a life of Michelangelo (2 vol. 1893). Essentially, he was an *homme des lettres*, diffusing his energies over English literature, Greek poetry, travel sketches, and a study of Walt Whitman (1893), of whom he was one of the first European admirers.

He died in Rome on April 19, 1893.

**BIBLIOGRAPHY.**—*Letters and Papers of John Addington Symonds* ed. by H. R. F. Brown (1923); H. R. F. Brown, *John Addington Symonds: a Biography*, 2nd ed. (1903), based largely on the unpublished autobiography; P. M. Grosskurth, *John Addington Symonds* (U.S. title, *The Woeful Victorian*; 1964). (I. Fl.)

**SYMOND'S YAT** (yat: gate, opening, pass), a low-lying neck of land, 12 mi. (19 km.) S of Ross-on-Wye, Herefordshire, Eng., between Huntsham Hill (475 ft.; 145 m.) to the north and the famous viewpoint Yat Rock (about 500 ft.) to the south, in the Carboniferous Limestone upland. It is bounded east and west by a meander of the River Wye which, in its 4-mi. (6.4-km.) course round Huntsham Hill, progresses westward only 600 yd. (550 m.); i.e., the width of Symond's Yat. (Au. M.)

**SYMONS, ARTHUR WILLIAM** (1865–1945), the first English critic to advocate the importance of the French Symbolists (*q.v.*), was born at Milford Haven, Pembrokeshire, on Feb. 21, 1865. His schooling was irregular, but, determined to be a writer, he soon found a place in the London literary journalism of the 1890s. He joined the Rhymers' Club, contributed to the *Vellum Book*, and became editor of the *Savoy* (January–December 1890), with Aubrey Beardsley (*q.v.*) as art editor. Symons was versed in European literature, and his popularizing *Symbolist Movement in Literature* (1899) summed up a decade of interpretation and influenced both W. B. Yeats and T. S. Eliot. His criticism constitutes an ambitious attempt to create a general "aesthetic" from the unsystematized "impressionism" of Walter Pater (*q.v.*). Where Pater had isolated music as the type of all the arts, Symons' premise, in *Plays, Acting, and Music* (1903) and *Studies in Seven*

*Arts* (1906), was that "each art has its own laws, its own limits; these it is the business of the critic jealously to distinguish. Yet in the study of art as art, it should be his endeavour to master the universal science of beauty."

Symons' poetry is mainly *fin de siècle* in feeling, though it influenced Yeats in his middle period. *Silhouettes* (1892) and *London Nights* (1895) contain admirable impressionist lyrics, and at his best Symons is sensitive to the complex moods of urban life. His translations from Verlaine are notable, and he wrote elegant travel pieces.

In 1908 Symons suffered a severe mental breakdown, and, apart from *Confessions* (1930), which is a moving account of his illness, his career was virtually over. Other works included, in verse, *Images of Good and Evil* (1899), *The Fool of the World* (1906), and *Knave of Hearts: 1894-1908* (1913); and, in prose, the remarkable, partly autobiographical *Spiritual Adventures* (1905), and *Studies in the Elizabethan Drama* (1920). He died at Wittersham, Kent, on Jan. 22, 1945.

See his *Collected Works*, 9 vol. (1924; incomplete); R. Lhombreud, *Arthur Symons* (1963). (I. Fl.)

**SYMPATHETIC SYSTEM:** see NERVOUS SYSTEM: *Autonomic Nervous System*.

**SYMPHONIC POEM (TONE POEM):** see PROGRAM MUSIC.

**SYMPHONY**, a musical term which since the middle of the 18th century has denoted a type of composition for orchestra; the classical symphony is in sonata form. The word is derived from the Greek *symphonia*, "concord." In Luke 15:25, *symphonia* is distinguished from *choroi*, and the two are translated as "music and dancing." The word has also been applied to two musical instruments, the sistrum in ancient times and the hurdy-gurdy in the Middle Ages.

In the 17th century the term was used, like "concerto," for certain vocal compositions accompanied by instruments; e.g., the *Symphoniae sacrae* of Heinrich Schütz. The term is also found in Schütz's *Kleine geistliche Concerte*, where it is applied to the instrumental ritornello of a song.

**Origins.**—Since the middle of the 18th century the interpretation of the term symphony has become freer, but any work bearing this name requires close scrutiny. Preoccupation with vocal counterpoint until the 17th century ensured that musical designs remained essentially static. Tonality was a kind of anchor, and the music consisted of simply related harmonies. As instrumental techniques developed, greater freedom of line, harmony, and to some extent tonality became possible, though for a long time composers tended to regard instruments as if they were more agile and brilliant voices. This applies to Bach in the first half of the 18th century; Handel shows more sense of adventure in this respect, but his work is still basically polyphonic. In a prelude of Bach or a movement of a *concerto grosso* by Handel the treatment of key (tonality) is totally undramatic; the music swings from harmony to related harmony without more than a hint that it is ever likely to move out of an orbit centred on its original key. The harmonic scheme, in fact, is as calm and relaxed as that of a simple hymn tune whose successive chords are now spun out to accommodate elaborations of the texture, mainly of a contrapuntal nature. At the end of such a piece, no impression of movement is created. Violent changes of mood or texture are rare and real changes in tonality almost impossible. When Bach in the B minor Mass passes through mysteriously "foreign" harmony at the words *et expecto resurrectionem mortuorum* his purpose is expressive rather than structural; it is a way of drawing attention to the nature of the text at this point and of making a convincing transition between the F# minor of the *Confiteor* and the brilliant D major of the exultant movement, separately designed, which follows it. This is the process of modulation (*q.v.*), and real modulation in music before the early 18th century is usual only in such transitions between otherwise independent designs. It is scarcely ever found within the course of a homogeneous movement, where it would be disrupting to the calmly proportioned architecture.

The concept of modulation, however, is at the root of the sonata principle. While Bach was perfecting his polyphonic art, other composers (including his sons) were creating a kind of music that

was entirely based on instrumental as opposed to vocal technique. Counterpoint is almost entirely dispensed with in these early examples, which aim at achieving maximum mobility in terms of simple chordal harmonies and rhythms. Their straightforward themes, often founded on triads, would have been utterly unsuitable as contrapuntal subjects. The use of simple harmony made it imperative to find a new means of contrast, and it was found that an increase of tension resulted from the music moving from one tonal region to another. The rhythmic impulse was at the same time sustained, or even intensified, so that there was no sense of discontinuity, but on the contrary a sweeping momentum hitherto unknown. When the new tonal region was reached, some kind of momentary relaxation was provided, leading perhaps to a new theme, possibly more ingratiating than the first. The so-called first and second subjects referred to in textbook analyses of sonata forms thus arose from a new attitude to tonality. To regard them merely as conveniently contrasting themes is to divest them of their underlying dynamic purpose. The second subject is not necessarily a "tune" at all; it begins at the moment when modulatory tension relaxes into a new channel—a new theme may or may not emerge. The essence of sonata music lies in its newfound ability, in the 18th century, to thrust a key away over the tonal horizon, so that a new vista is created. (See also SONATA.) This was the nature of the new dynamism in music. Composers of this new kind of music, if it was written for orchestra, called it symphony, and it originated in the theatrical or operatic overture, often termed *sinfonia* (see OVERTURE). The fresh sense of movement permeated all kinds of music, but the word symphony thereafter was almost exclusively applied to orchestral works.

**Haydn, Mozart, and Beethoven.**—At first there was little to distinguish the early symphony from the divertimento or cassation (*q.v.*) or even from the string quartet. The orchestra itself became more stabilized, with the strings as its basis, at first with the keyboard *continuo* to keep a "middle" going, but gradually doing away with this device as wind instruments were more extensively and skilfully used. Oboes and horns, in pairs, were used in many symphonies of the 1750s and 1760s. Flutes and bassoons were added, and trumpets and drums for special ceremonial occasions. The orchestra thus developed into a standardized unit, homogeneous as, say, the keyboard. As soon as the orchestral *tutti* became a norm, composers were free to explore its depths. Haydn, even in his earliest symphonies, thus had a ready-made instrument allowing him to compose unselfconsciously; and he owed this fact to G. M. Monn, G. B. Sammartini, and G. C. Wagenseil, even more than to J. W. Stamitz, founder of the Mannheim orchestra and the school of composers it inspired. Haydn was not the father of the symphony; he was its progeny. Nevertheless, it was due to him that the title "symphony" came to denote an orchestral work of the highest concentration, organization, and comprehensiveness.

The early operatic overture was often in three movements—an allegro, a slow movement, and a lively finale, often in fast triple or sextuple time, upon which the curtain rose. It is often supposed that the succession of movements in a classical symphony originated here, but contrasting movements became more necessary than ever when the explosive tensions of tonality were released. Everything that happens in such music is born of tonal tension, even the division into separate movements that had previously been no more than decorative. To the three movements a minuet was added. This served two purposes: first, to increase the sense of comprehensiveness by including a dance element, and second, to complement the brevity of the finale. So the four-movement symphony became a normal format that persisted almost unchallenged for 100 years and is still not discarded. Haydn and Mozart are the first complete masters of the symphony who were concerned with the felicitous interpenetration of certain prime elements—pure formal balance, concentration, variety of expression within the same work, and what may be called athleticism. With them, the symphony became a complete kind of orchestral music, and the term symphony has ever since been used to arouse the listener's highest musical faculties.

The greatest intensification of this challenge was made by

Beethoven. He did not surpass Haydn or Mozart in perfection of design, or even in sheer athleticism; in concentrated depth and variety of expression, however, mastered within the physically limited yet imaginatively vast confines of single works, no composer before or since has approached him. It was this attribute that made Brahms—one of his most masterly successors—fearful of composing symphonies at all. Beethoven, moreover, widened the scope of the orchestra itself, by increasing the number of instruments, adding an extra horn in No. 3 (*Eroica*), and trombones in No. 5, 6, and 9, sometimes also using piccolo, contrabassoon, and (in the Ninth) extra percussion. He also tended to place more weight on the finale of a symphony than did his precursors, especially in No. 5, 7, 8, and 9; in the latter, the last and greatest of the series, he took the unprecedented step of adding a chorus and vocal soloists to the finale.

**Later Developments.**—After Beethoven the Romantic movement of the 19th century was inclined to inflate the idea of symphony, expressive intensity arising from a high degree of subjectivity often being allowed to oust the more rigorous formal considerations; Beethoven's music cannot be held responsible for this, since no other composer, except possibly Bach, was so aware of structure, no matter how fierce or dramatic the expression. This gave his work an objectivity that is the reverse of Romantic. Some loosening of the discipline may be noticed in Schubert, though one should be careful not to confuse this element with positive new discoveries made by Schubert involving a more deliberate pace of thought. Nineteenth-century composers who showed resistance to the tendency to inflation and loose discipline—clearly followers of Beethoven and Schubert—are Schumann (whose great economy is often overlooked), Brahms, and Dvořák; they maintained classical traditions and classical energy while achieving complete individuality. Two early-19th-century symphonists of essentially 18th-century makeup were Mendelssohn and the Swedish composer F. A. Berwald, both of whom show less concern with the heroic than with elegance and balance.

The composers just mentioned may be said to represent one trend, perhaps the most faithful to the essential nature of the symphony as it had so far developed—not because of adherence to any rule book but because they strove to achieve a fine balance between the complexities of form and the more importunate demands of expression, on a scale comparable with that of the classical symphony. At the same time, the Romantic preoccupation with the emotional moment was inevitably slowing down the pace of music; it was becoming increasingly difficult to write a true allegro; Schubert's retardation of pace was a beginning, and Wagner's discovery of how to make musical structures large enough to encompass a whole act of a stage drama (and "large enough" means "slow enough") had an overwhelming effect upon other composers whose aims were unconnected with the theatre. The most notable of these was Bruckner, who, while creating music that has an individual grandeur—in spirit perhaps closer to Giovanni Gabrieli than to Wagner—constructed vast symphonies whose motion is for the most part of huge slowness, which would have been impossible without Wagner's influence. Wagner's sense of movement had also a deep effect on Mahler, who also wrote symphonies on an enormous scale, for enormous orchestras; here, however, subjective Romanticism sometimes intervenes at moments when structural demands might have been better met.

**The 20th Century.**—Mahler brings the history of the symphony up to the beginning of the 20th century. Parallel with German Romanticism, the Russian nationalists, particularly Borodin, M. A. Balakirev, and Tchaikovsky, were also producing an individual conception of the symphony. Tchaikovsky, however, proved to be less a nationalist than a subjective Romantic, whose violent emotional impulses frequently broke down discipline in a formal method derived largely from Schumann. Tchaikovsky's symphonies, like Mahler's, are basically programmatic in character, and to that extent only sporadically symphonic, for the expressive-illustrative elements sometimes ignore structural necessities. A movement such as the first of Tchaikovsky's Fourth Symphony, however, achieves a just balance, such as the Frenchman Berlioz (who greatly influenced him) more often found.

The structural concentration of true symphony has not attracted French composers, and Berlioz (nearest in time to the classical symphonists—he began his *Symphonie fantastique* while Schubert was writing his great C major symphony) is still the finest French symphonic composer, whose best work is purer and more controlled than his reputation for Romantic illustrative extravagance would lead the casual listener to believe.

While German Romanticism was reaching the limits of inflation at the end of the 19th century, two Scandinavian masters were renewing the classical symphony by making fresh discoveries, Jean Sibelius with the concept of movement, and Carl Nielsen with that of tonality. Their reactions against the indiscipline of Romanticism are essentially complementary. The slowing down of musical movement mastered by Wagner had two serious effects on his successors: (1) many composers lost the power of classical movement, the ability to write the kind of allegro whose impetus is exemplified in Haydn and Beethoven; (2) tonality was no longer being used coherently, for the slowness meant that the conception of key as an "anchor" could no longer easily be sustained in such a time scale. Sibelius, for the first time, found a way to combine the vast slowness of the Wagnerian world with the athleticism of Beethoven, and his series of seven symphonies is a progressive mastering of this problem, culminating in the one-movement Seventh, in which transitions from one extreme to the other are made with astonishing skill and imaginative power. Sonata "form" no longer applies, but the disciplines are all derived from the phenomena that sonata music made possible, and the range of expression is comparable with that of the fully developed four-movement classical symphony.

This is true also of Nielsen's six symphonies, but here the discovery is tonal. The originality of this Danish composer lay in his clear understanding of the problem that was baffling the Romantics, whose dilemma was the result of a single great assumption—that tonality must be an "anchor." Arnold Schoenberg, who plunged into atonality and devised new serial disciplines to compensate for the loss, did so because he also shared this assumption, as is shown by his remark that "there is still a lot of good music to be written in C major." The operative phrase here is "in C major," with its suggestion of fixity. Nielsen discovered a structural way of making a symphony travel from one tonality—or sometimes a complex of warring tonalities—to another. The phenomenon is sometimes called progressive tonality, though emergent tonality would be a more accurate description. From it Nielsen was able to produce a new dynamism and music of great strength, as well as variety of character.

The reaction to the general slowing down of musical processes that came with the twilight of Romanticism has, in the 20th century, been more often negative than positive, and compositional methods have tended to produce totally static rather than dynamic results. Therefore valid symphonic music is rarer than in the past. Composers of the mid-20th century who have used the title have often done so loosely. It is no longer indicative of any particular method or format. Since, however, the term "symphony" has been the highest challenge in the field of orchestral music for many of the greatest composers of the last 175 years, it will no doubt continue to be applied to works in which the composer has essayed the widest range of expression and movement within the scope of a single work. The essence of symphony is disciplined inclusiveness; that is to say, the comprehensiveness of symphony will not exclude any natural resources of music—harmony, melody, rhythm, tonality, etc. Any avoidance of one such element, however concentrated, must necessarily bring about a sense of exclusiveness that will inevitably limit the music to less than the widest powers of the imagination. A symphony must be genuinely and consistently active if it is to rise to its proper level; it is by this standard, by which the greatest symphonists have survived, that it must stand or fall. Its actual form is no longer definable or predictable.

**SYMPHYLA**, a class of small, many-legged arthropods (myriapods), the largest representatives being slightly less than

one centimetre in length. The skin of these animals is thin, soft and colourless. They live under logs, leaves and stones, where their white bodies contrast sharply with the darker soil. Although symphylids occasionally devour dead insects, they usually subsist upon decaying vegetable matter and delicate rootlets and tissues of living plants. One species in particular, *Scutigereilla im-maculata*, is known to do extensive damage to such crops as celery, lettuce, asparagus and beets. This form is often spoken of as the "garden centipede," although the absence of poison jaws and other basic differences widely separate it from true centipedes (q.v.).

As in other myriapods, so-called, the head is distinct. The body is composed of 14 segments, bearing 15, or rarely 22, dorsal plates, or tergites. Twelve pairs of usually five-jointed legs are present, one pair to each of the first twelve segments. The head, which bears a Y-shaped dorsal suture like that of insects, lacks eyes and bears a pair of long, many-segmented antennae. The mouthparts include a pair of mandibles, a pair of maxillulae (paragnatha) and two pairs of maxillae of which the second pair combine to form a labium as in insects and centipedes. Only one pair of respiratory spiracles are present; these open on the head near the bases of the antennae and allow air to all parts of the body via tubules called tracheae. The paired reproductive organs open by a single pore lying between the third and fourth pairs of legs, a characteristic placing them with millipedes and pauropods in the now widely recognized group Progoneata. The females lay their eggs in clusters in the ground. As with the millipedes, the young hatch out with three pairs of legs, the rest being developed later.

The symphylids have a world-wide distribution. Because of neglect by most collectors only about 100 species have so far been recognized. Formerly, they were placed in three families, two of which have been placed with the centipedes, the family Scutigereillidae remaining. The name Symphyla refers to the intermediate position of these animals, all of which show obviously connecting characters with other groups of tracheate arthropods, especially insects.

Michelbacher, "The Biology of the Garden Centipede *Scutigereilla im-maculata*," *Hilgardia*, vol. 11, pp. 55-148 (1938). (R. V. C.)

**SYNAGOGUE**, a Jewish house of worship. In Hellenistic Greek, *synagoge* was the term for assembly and later for the place where the assembly gathered, corresponding to the Hebrew *keneset* and *bet ha-keneset*. The phrase "meeting places of God" in Ps. 74:8 is generally assumed to be a reference to synagogues (and was so translated in the Authorized Version). Talmudic literature also uses the terms "house of the people" (based on Jer. 39:8) and "small sanctuary" (based on Ezek. 11:16) while Greek sources speak of "house of prayer" (*proseuche* or *proseukterion*) and occasionally "sabbath house." In modern times "temple" and *shul* (Yiddish, from the German *schule*) are common. United States usage often distinguishes between a temple, meaning a Reform Jewish synagogue, and a *shul*, an Orthodox Jewish house of worship.

## SYNAGOGUE HISTORY AND FUNCTIONS

**History.**—The beginnings of the synagogue are obscure. It most probably originated during the Babylonian Exile as an institution for public worship and instruction soon after the destruction of Solomon's Temple in 586 B.C. (see **TEMPLE, JEWISH**). After the return from the Babylonian Captivity, especially under

FROM MICHELbacher IN "HILGARDIA" (UNIVERSITY OF CALIFORNIA)

ADULT SYMPHYLID (SCUTIGEREILLA IMMACULATA)

Ezra and his successors, the synagogue developed side by side with the cult of the Temple in Jerusalem. Some scholars trace the origin of regular worship in the synagogue to the institution of Maamadoth, which formed part of the Temple worship; along with each of the 24 priestly divisions, certain towns would arrange for a two-week assembly of prayer and worship. The oldest dated evidence of a synagogue is the dedication of a house of worship to Ptolemy III (3rd century B.C.) inscribed on a marble slab discovered near Alexandria, Egy. Approximately 50 ancient synagogues were excavated in Palestine and the surrounding area during the 19th and 20th centuries, but they all date from the 2nd to the 6th century A.D. Philo and Josephus, as well as the New Testament and the early rabbinic sources, speak of the synagogue as an institution that had been in existence from early antiquity. The literature of the 1st century also refers to numerous synagogues not only in Palestine but in Rome and Greece as well as in various cities in Egypt and Babylonia and throughout Asia Minor. Toward the end of the second commonwealth (middle of 1st century A.D.) there were synagogues wherever there was a Jewish settlement of sufficient size to support organized congregational activity. The destruction of the Second Temple by Titus (A.D. 70) had no adverse effect on the synagogue, which had long been a well-established and independent institution. During the centuries following the fall of Jerusalem the synagogue gained in importance, becoming the centre of the corporate life of the Jewish community.

**Character.**—The character of the synagogue, often termed "the child of the dispersion," represented from its inception a radical departure from that of earlier places of worship. It was not restricted to any geographic locale that presumably possessed inherent sanctity; it had no sacrificial or sacramental ritual; it did not require the intermediacy of a special priesthood. Any group of Jews, regardless of place, may establish a synagogue and share the responsibility for the conduct of its affairs. Essentially democratic, the synagogue represents a fellowship of worshipers seeking God through prayer and study.

Certainly from the 1st century A.D., and probably much earlier, morning, afternoon, and evening services were conducted in the synagogue daily and on the sabbaths and festivals (see **LITURGY, JEWISH**). On special occasions, especially on the sabbath, the service included a sermonic exposition of the scriptural lesson as well as public lectures on various aspects of the law. The facilities of the synagogue, particularly the rooms adjoining the main prayer

WERNER BRAUN

PULPIT AND WOMEN'S GALLERY OF CONEGLIANO VENETO SYNAGOGUE, 1701. MOVED FROM VENICE TO JERUSALEM IN 1940

hall, were often employed for a variety of other purposes throughout the ages. They served as the meeting place for the leaders of the community and for popular assemblies, for publication of legal notices and decrees of the secular government (during the medieval period), for funerals of its leading members and rabbis, for weddings, circumcisions, and, at times, even for lodging of travelers. Above all, the facilities of the synagogue were used for the education of children. The modern synagogue provides regular public worship, a program of education for children, youth, and adults, and a variety of social, cultural, and philanthropic activities.

**Architecture.**—There is no typical synagogue architecture; the houses of worship were and are built in the prevailing architectural style. Numerous synagogues built after World War II are among the finest examples of advanced architectural design. The only prescriptions found in the Talmud are that the synagogue be built on the heights of a city and that it have windows ("light dwells with Him," Dan. 2:22; and of Daniel praying, "he had windows in his upper chamber open," Dan. 6:10), but even these few requirements are only theoretical. The modern synagogue usually contains an ark where the Scrolls of the Law are kept; a light above the ark called the eternal light or perpetual lamp; two candelabra; pews for the worshipers; and a raised platform, *bimah* (or *almemar*), from which the scriptural lesson is read and, often, services conducted. In the medieval synagogue, the *bimah* was usually located in the centre of the auditorium and a gallery was built in the back or on the sides of the auditorium for women worshipers. Also, a *mikvah*, a ritual bath, occasionally was included in the synagogue premises. Many Orthodox synagogues today retain all or several of these features. (See also RELIGIOUS ARCHITECTURE; JEWISH ART.) (E. M.)

### SYNAGOGUE ORGANIZATIONS

**United States.**—Each Jewish congregation is an independent entity, governed in most cases by an elected board of directors. Nearly all describe themselves as Reform, Conservative, or Orthodox (see JUDAISM). No precise figures on the relative strength of the three are available, but it is believed that in the United States their numbers are approximately equal.

In the past, Orthodoxy was strongest in New York City and in the Middle Atlantic and New England areas. In smaller cities of the Midwest, South, and Far West the Reform temple was frequently the most prominent Jewish religious institution. Conservatism centred in some of the largest Jewish communities, though it was not especially prominent in New York. The evolution of American Jewry, however, changed this picture considerably. Thus, the movement of the Jews of New York City to the suburbs added strength to Reform and Conservatism; the growth of Los Angeles as a centre of Jewish population meant the strengthening of Conservatism and Orthodoxy in that area.

In regard to the constituency of each group, the most notable trend is the general decline in social-class differences. Many present-day Reform congregations, in contrast to those of an earlier period, include few if any persons who are members of the upper class. The constituency of Reform is now also overwhelmingly composed of persons descended from immigrants who originated in Eastern Europe rather than in Germany. While the Orthodox group is extremely variegated in composition, it still possesses the strongest links with the immigrant past. However, Orthodoxy increasingly utilizes American methods of organization, and in many Orthodox congregations English has replaced Yiddish as the language of common discourse.

National synagogue federations exist in the United States for each of the three groups: (1) the Union of American Hebrew Congregations for the Reform group; (2) the United Synagogue of America for the Conservative group; and (3) the Union of Orthodox Jewish Congregations of America for the Orthodox group. The Reform federation, founded in 1873, is the oldest and the best organized of the three. The Conservative federation, founded in 1913, was relatively inactive until the 1940s, becoming after that period, however, an important agency. The Union of Orthodox Jewish Congregations, although founded in 1898, has

remained a loosely organized group. Most Orthodox congregations are small in size and do not have ties with any national body. The synagogues affiliated with the Young Israel movement, however, have achieved a measure of coordination, and the Yeshiva University Synagogue Council also has become a force in the Orthodox group.

During the 19th century some thought that all synagogues might affiliate with a single federation—hence names such as "Union of American Hebrew Congregations," or "United Synagogue." Today, however, even those who foresee a single "American Judaism" conceive of this as a far-off development. The Synagogue Council of America, which is composed of both rabbinical and lay representatives from each of the three groups, has confined its efforts to representing the common interests of Reform, Conservatism, and Orthodoxy before interreligious and governmental bodies.

American Jewish congregations have typically been organized by local residents who join together, hold services, start a religious school, and raise funds for a synagogue building. Initially at least it is the members themselves who shape the exact religious complexion of the congregation. They decide whether the group should affiliate with one of the national synagogue federations. However, after World War II the federations themselves became somewhat active in promoting the establishment of congregations. Substantial variations exist in each movement, and they tend to overlap. The national bodies have been generally hesitant to promulgate detailed codes of doctrine, though they publish textbooks, magazines, and diverse pronouncements for the guidance of their member congregations.

In many cases the synagogue has added an extensive list of activities to its traditional function of providing a place of worship and a centre for study by male adults of the sacred Jewish texts. Congregations increasingly become "synagogue centres" and sponsor club programs, athletic activities, and public lectures. They make their facilities available for a variety of Jewish and general communal purposes. Many congregations possess affiliated organizations, such as sisterhoods, men's clubs, and youth groups, which provide a varied program, generally with an emphasis on social activities. Sisterhoods, men's clubs, and youth groups are affiliated with federations sponsored by the national bodies.

The task of providing elementary Jewish education also has become a congregational rather than a communal responsibility. An important motivation for congregational affiliation is the desire to enroll children in the religious school of the institution.

The religious life of Canadian Jewry is essentially the same as that of the United States. Canadian synagogues belong to any one of the three U.S. congregational bodies. (M. S.)

**Great Britain.**—In Great Britain synagogues are generally classified as Orthodox, Reform (similar to Conservative in the United States), or Liberal (similar to Reform in the U.S.). Most of these congregations are in Greater London, and the remainder are scattered in about 110 provincial communities. Historically, the oldest congregation is the small Orthodox Sephardic (Spanish and Portuguese) community, which dates from the Jewish Resettlement in 1656 and whose religious head is the *haham*. Its central synagogue in Bevis Marks in the City of London was built in 1701.

The largest religious body is the United Synagogue (Orthodox), established by act of Parliament in 1870, although its origins date back to the Ashkenazic settlers from Central and Eastern Europe at the end of the 17th century. This administers synagogues in the Greater London area. Its religious head is the chief rabbi of the United Hebrew Congregations of the British Commonwealth whose general authority is also recognized by some of the other Orthodox synagogues in London, the provinces, and overseas. The congregations of the Federation of Synagogues (established 1887) and the Union of Orthodox Hebrew Congregations (established 1926) represent the more right wing of Orthodoxy; while the left wing is represented by the New London Synagogue, which separated from the United Synagogue in 1964.

Reform synagogues have grown from one in 1840 to about 24, and Liberal synagogues from one in 1902 to about 20. They are

all affiliated to the World Union for Progressive Judaism. Members of different synagogal bodies unite in philanthropic, welfare, and cultural work; and the Board of Deputies includes representatives of all religious sections of British Jewry. (H. HA.)

**SYNAPSE**, the functional conjunction between two neurons (nerve cells), making conduction of nervous impulses continuous from one to the other. Synapses occur between the axon terminations of one neuron and the cell body of an adjacent neuron (axosomatic synapse); or between axon terminations of one neuron and the dendrites of the next (axodendritic synapse). In some cases adjacent neurons are connected by both types of synapse; the term synaptic junction is used to describe this functional and anatomical relation. (See NERVE; NERVE CONDUCTION.) The term synapse is also used in embryology to denote the pairing and union of the homologous chromosomes of the male and female pronuclei. This process is also named syndesis.

(W. M. M.; X.)

**SYNCRETISM**, the act or system of blending or reconciling inharmonious elements. The correct etymology of the word is the punning one given by the ancient Greek author Plutarch, who explains in his *De fraterno amore* that the Cretans stopped their internecine strife and united when attacked by a common outside enemy; this they called *synkretismos* ("Con-Creting"). Later the term was used of tendencies or systems aiming at reconciling divergent philosophies or hostile theological factions. In this sense it was applied to the endeavours of John Cardinal Bessarion and others in the 15th and 16th centuries to harmonize the Aristotelian and Platonic philosophies, as well as to the attempts of the Lutheran theologian Georg Calixtus in the 17th century to bring together the warring factions—Lutheran, Reformed, and ultimately also Catholic—of the church. By that time the term had acquired a pejorative flavour; in the "syncretistic controversy" between Calixtus and Abraham Calovius it appears as synonymous with "Samaritanism" (referring to the mixed Israelite-pagan religion practised, according to II Kings 17:24–41, by the foreign colonists settled in Samaria). The underlying idea of mixing heterogeneous elements expresses itself also in the later etymology of the term (since Erasmus); the real etymology having been forgotten, the word came to be derived from the Greek *synkerannymi*, "to mix."

In a narrower and almost technical sense the term denotes the religious development of antiquity during the Hellenistic period and more particularly toward the end of the Roman Empire. Religious syncretism is generally the result of the contact and interpenetration of different cultures, and the meeting between Orient and Occident, initiated by the conquests of Alexander the Great, produced the cultural phenomenon known as Hellenism (see HELLENISTIC AGE: *Hellenistic Civilization*). Hellenism found an even wider and more unified arena in the *oikoumene* ("inhabited world") of the Roman Empire. The blending of different cults and mythologies promoted by this contact mainly took the form of an increasing penetration of Oriental religions to the West. The coexistence, within the confines of the empire, of various cults and religious systems led to a process of identification. This was abetted by the basic tolerance of polytheism, whose monotheistic tendencies develop by way of inclusion and not (as for example in the Bible) by way of the exclusion and rejection of all other deities.

The growth of philosophical speculation, and in particular of Neoplatonism, allied itself to that process, since the weakening of individual gods facilitated their interpretation as symbols of one common cosmic denominator or divine principle (e.g., the sun

in the later Roman cult). The system of allegorical interpretation as developed in the schools of Alexandria admirably lent itself to syncretistic use and in the hands of the pagan apologists proved a useful weapon against Christian polemicists. Deities were identified with one another on the basis of a genuine identity (e.g., Jupiter Capitolinus and Jupiter Latialis), of superficial outward or phonetic resemblances (e.g., Isis and Io, both being horned; Zeus Sabazius and the Jewish Sabaoth), or of functional or structural similarities (e.g., Roman Jupiter, Greek Zeus, and Persian Mithra, or the Great Mother as Isis, Ceres, Demeter, Cybele). The devotees of a particular cult would consider all other deities as expressions, names, or representations of the particular deity that was the object of their worship. Popular ritual traditions, mythologies, the mystery cults, astrology, priestly cosmologies, philosophical speculation, and magic all contributed their share to a flourishing syncretism. In the hands of reflecting philosophers, it became a conscious and systematic effort. The progressive hellenization of the early Christian message also may fairly be described as a syncretistic process, though scholarly opinion concerning its extent and significance is divided.

As an unconscious, natural development syncretism occurs wherever cultures meet. The biblical record contains indications of much popular syncretism between Israelite and Canaanite religion. An example of conscious theological syncretism can be found in Gen. 14:22 where Abraham identifies his God with Melchizedek's El Elyon ("God Most High"). Christian missionary activity in many parts of the world has produced a great variety of syncretistic forms of religion combining native with Christian elements. (This syncretism is to be distinguished, however, from conscious adaptation by missionaries to the forms of indigenous cultures, such as the "accommodation" advocated by the Jesuit mission in Malabar and China.) Islam, Buddhism (particularly the Mahayana), and Hinduism too have known syncretistic developments. Thus Buddhism and Zoroastrianism mingled in the state religion of the Indo-Afghan kingdom of Kanishka (q.v.) in the 2nd century A.D., and Hindu-Buddhist syncretism is much in evidence in Ceylonese popular religion. In 19th-century India, the movement called Brahmo Samaj (q.v.) endeavoured to fuse Hindu and Christian values. Many modern religious systems and cults, whether sophisticated (e.g., theosophy, the anthroposophy of Rudolph Steiner) or primitive (cargo cults; q.v.), are clearly syncretistic in character.

(R. J. Z. W.)

**SYNDICALISM**, an anticapitalist doctrine that stresses the autonomy of working groups and advocates direct industrial action to overthrow the capitalist order. Syndicalists thus differ from socialists, who advocate capturing the political state, whether by parliamentary or by revolutionary means, and enacting their programs. The syndicalists, like the anarchists, regard the state as inherently oppressive. For its control, they would substitute that of organized workers based on production units. The structure and administration of this proposed syndicalist community remain vague and utopian.

The syndicalist doctrine was first worked out by certain leaders of the French trade-union movement toward the end of the 19th century. The word *syndicalisme* means simply trade unionism; what is known in English as syndicalism the French call *syndicalisme révolutionnaire*. The movement flourished in France chiefly between 1900 and 1914 and had a considerable influence on other countries, especially Italy, Spain, and the Latin American nations.

It also had certain close resemblances to the direct action advocated in the United States at about the same time by the Industrial Workers of the World (q.v.). Like the French syndicalists, the IWW repudiated parliamentary action; but the IWW favoured strong, centralized unions rather than the typically small working units of the French syndicalists. There was also an analogous movement in Great Britain in the early decades of the 20th cen-

tury called guild socialism (*g.v.*), but it was greatly modified both by the traditional parliamentarism of the British working class and by the nonrevolutionary character of the movement's intellectual proponents. Nevertheless certain British trade unions were permeated by syndicalist ideas between 1906 and 1914.

After World War I, syndicalism ceased to be a dynamic force, even in France. Its followers tended to be attracted either by revolutionary Communism, especially as represented by the U.S.S.R., or by the increasing possibilities in Western democracies for socioeconomic improvements through ordinary trade-union activity and parliamentary action. However, syndicalism remained an important residual force, at least during the interwar years, in many European countries. Left-wing trade-union agitations, usually called Trotskyite by the Communists, often resulted from old syndicalist influence. In Spain, in particular, an anarchist opposition to Communist Party discipline existed in the 1930s. During this same period, the Italian fascist dictatorship of Mussolini sought to use syndicalist sentiment, in perverted form, in recruiting support for his corporate state (*g.v.*). Syndicalist overtones were also discerned in some of the support, but not in the leadership, of the British general strike of 1926. The failure of this strike, which was hardly revolutionary, did much, especially in Britain, to turn workers toward parliamentary action instead of direct industrial action to achieve political ends.

Syndicalists often claimed that theirs was the most proletarian of all radical social theories and owed the least to middle-class theorists. This was true of its origin but hardly of its later development by Georges Sorel, whose exposition *Reflections on Violence* (1908) is the best-known syndicalist work. Sorel introduced into syndicalism the notion of social myths by which the workers could be irrationally stirred to revolutionary action. The general strike, advocacy of which the syndicalists had taken over from the anarchists, became in Sorel's hands a myth of this kind.

The syndicalist started from the assumptions common to most schools of socialist thought. He affirmed the inherent injustice of the wage system and the fundamental immorality of capitalist society, based, in his belief, on the exploitation of labour. He accepted and pushed to its logical conclusion the Marxian dogma of the class war; he therefore affirmed that solidarity of interests does not, and cannot, exist between capitalists and wage earners. From these premises he drew the usual socialist conclusion: that individual ownership of the instruments of production must be abolished and communal ownership and control substituted for it. But at this point syndicalism and socialism parted company. Whereas the socialist demanded ownership by the state and its dependent organs, such as the municipalities, the syndicalist demand was for direct ownership and control by the workers, acting through the organizations of their own creation—the trade unions and federations of unions.

State organization and control of industry are, in the syndicalist view, incompatible with true working-class emancipation. The state is, and must be, an instrument of class domination; it is, indeed, "the executive committee of the capitalist class." It exists to defend the interests of that class and is consequently as much the enemy of labour as capital itself.

The state is, moreover, hopelessly wedded to an uncreative bureaucracy, incapable of initiative and ignorant of industrial technique. Its control, even if it were benevolent (which the syndicalist denies it could be), would necessarily be despotic and inefficient; the spirit of routine would combine with inexperience to crush out the possibility of economic progress. Here the syndicalist endorsed the ordinary individualistic criticism of state socialism. Workers' control, exercised through the *syndicats*, would combine freedom with efficiency.

The form of social organization in which this ideal could be realized was ordinarily conceived somewhat as follows: The unit of organization would be the local *syndicat*. This would be brought into touch with other groups by means of the local *bourse du travail* ("labour exchange"), the established function of which was to act as an employment agency and a general centre for trade-union activities. When all the producers were thus linked together by the bourse, the administration of the latter would be able to

estimate the economic capacities and necessities of the region could coordinate production, and, being in touch through other bourses with the industrial system as a whole, could arrange for the necessary transfer of materials and commodities, inward and outward. A species of economic federation would thus replace the structure of capitalist industry, along with which the political and administrative machinery of the state would necessarily disappear.

Two features of this utopia need to be emphasized: consumers as such were excluded from any share in industrial control, and a localized system of industry was envisaged. This latter feature was a direct reflection of economic circumstances in France; both industry and trade unionism were much more local in range than in other and more highly developed countries. But the movement toward large-scale organization, which so profoundly affected every aspect of modern economic life, produced a corresponding modification in later syndicalist ideals.

Syndicalist theory starts from the idea of a class war, which must be waged relentlessly till a complete social transformation has been accomplished. The essential weapon in this struggle is the power of the organized workers. As the cause of the conflict is economic it must necessarily be fought out in the economic sphere. Syndicalist congresses thus persistently repudiated political action and pinned their faith to a general strike as the grand instrument of social revolution. This reliance upon industrial or direct methods of action flows necessarily from the fundamental notions of syndicalism as to the nature of the state, and also from strictly practical considerations.

Outside the mine or factory, workingmen hold divergent religious or political opinions that make effective mass action difficult, if not impossible. Inside, the nature of their employment gives them a sense of solidarity that overrides other differences and bands them together in the *syndicat* for common defense. To persuade them to pass from the defensive to the offensive is the syndicalist's task, and in the accomplishment of this, political labels and controversies would be a hindrance. The strike, therefore, is the characteristic syndicalist weapon. However limited in its scope and object, it is an educative experience. Successful, it inspires the workers with a sense of power; unsuccessful, it impresses upon them the servility of their lot and the necessity for better organization and wider aims. Thus, every strike is a preparation for the revolutionary day when the workers, or a fighting minority of them (for syndicalism repudiates as bourgeois the dogma of the sacredness of majority rule), shall seize the instruments of production by an expropriatory general strike. In the meantime, they are working out from day to day, in the ordinary course of their employment, the ethics and the jurisprudence of the new social order.

The syndicalist idea, as understood in France, may be said to have developed out of the strong anarchist and antiparliamentary traditions of the French working class, and to have been much influenced by the teachings of P. J. Proudhon and, on another side, by Louis Auguste Blanqui. A French delegate to the congress of the International Working Men's Association (known as the First International) held at Basel in 1869, for instance, prophesied that "the grouping of different trades in the city will form the commune of the future" when "government will be replaced by federated councils of *syndicats* and by a committee of their respective delegates regulating the relations of labour—this taking the place of politics."

These tendencies manifested themselves with increasing strength during the 1890s in the two main labour organizations of the period—the Confédération Générale du Travail (or CGT) and the Fédération des Bourses du Travail. The secretary of this latter organization, Fernand Pelloutier, did more perhaps than any other individual in his day to work out the characteristic doctrines of syndicalism and to spread them among his fellow workers. When these two bodies joined forces in 1902, trade unionism in general and syndicalism in particular received an immense accession of strength; and the syndicalist doctrine subsequently remained—in spite of the efforts of political socialists to capture the *syndicats* for their own purposes—the characteristic expression of

French revolutionary idealism until World War I. Thereafter, as noted above, it ceased to be a strong force. See FRANCE: *Administration and Social Conditions*. **SYNGE, JOHN MILLINGTON** (1871-1909), Irish writer who helped bring about the literary renaissance of the 1890s (see IRISH LITERATURE). Born at Rathfarnham, near Dublin, on April 16, 1871, he was educated privately and (1888-92) at Trinity College, Dublin. A keen ornithologist, he early learned the self-effacement that was to help him observe peasant life. After studying music, from 1893 to 1898 he wandered about Europe, and had already written verse and criticism when, in Paris in 1896 or 1897, he met William Butler Yeats, who told him: "Go to the Aran Islands. Live . . . as if you were one of the people . . . ; express a life that has never found expression."

He spent part of 1898-1903 on the islands, describing his experiences in the haunting *The Aran Islands* (1907); his first one-act plays, *The Shadow of the Glen* (1903) and *Riders to the Sea* (1904), were based on stories heard there. His first three-act play, *The Well of the Saints*, was produced at the Abbey Theatre (q.v.) in 1905; it was followed in 1907 by *The Playboy of the Western World*, which by its realism shocked audiences who had be-

come used to the nationalist idealism of Yeats and Lady Gregory. Synge died of cancer in Dublin on March 24, 1909, leaving unfinished his most poetic play, *Deirdre of the Sorrows* (Abbey Theatre, 1910). A collection of poems, written in 1896 after an unhappy love affair, and in 1907-08, after his engagement to Molly Allgood (Maire O'Neill), was published in April 1909.

Synge was the greatest dramatist of the Irish literary renaissance. His understanding of the Irish peasant, his detached, unsentimental compassion, and delight in the vitality—even violence—of peasant life, and his "fiery, magnificent and tender imagination" enabled him to blend irony with a tragic and elemental power. He molded the syntax and idioms of Gaelic into a unique poetic diction, capable both of rising to musical heights and of serving as a lively instrument for his ironic humour.

**SYNGE, RICHARD LAURENCE MILLINGTON** (1914- ), British biochemist, was awarded the 1952 Nobel Prize for Chemistry jointly with Archer John Porter Martin (q.v.) for their method of identifying and separating chemical elements by chromatography. He was born on Oct. 28, 1914, at Liverpool and educated at Winchester College and Trinity College, Cam-

bridge. At Cambridge and in the Wool Industries Research Association's laboratories at Leeds he collaborated in chemical research with Martin. In 1943 he was appointed to the Lister Institute of Preventive Medicine, London, and from 1948 he worked at the Rowett Research Institute, Bucksburn, Aberdeenshire. He was elected fellow of the Royal Society in 1950. Partition chromatography (q.v.), devised by Martin and Synge, effected the partition of a substance between two liquids by very simple means instead of by a series of intricate chemical operations, and it became so widely used in chemical, biological and medical research as to constitute almost a new scientific tool. In 1951 Synge, with four other scientists, formed a "science for peace" committee.

**SYNOPTIC GOSPELS:** see GOSPELS.

**SYNOPTIC WEATHER CHART**, a term used peculiarly in meteorology for maps of any large or small portion of the globe, on which are plotted weather observations taken at various points over the area represented and at approximately the same time. In addition the data on the map are usually analyzed by means of conventional symbols, isolines, and shadings (see WEATHER FORECASTING).

The expression weather map or weather chart is essentially synonymous with synoptic chart. The adjective synoptic implies a brief or condensed means of presenting a combined or general view of something; but in meteorological parlance the word came to have the connotation of synchronous because, according to most schools of meteorology, only synchronous weather observations lend themselves to rational analysis of maps that are to be used for the purpose of preparing forecasts. The notable exception is in the U.S.S.R., where the official weather maps are not based on entirely synchronous observations but on observations made at the same local sun time.

Synoptic charts are constructed in various forms according to their purpose and the kind of data plotted on them. The basic chart for the use of forecasters is that which shows the synchronous observations at sea level or surface stations over a more or less extended area, generally at least a large part of a continent and often a whole hemisphere. For each weather station whose observations are taken at internationally standardized synoptic hours—one to four times a day—and received by radio or telegraph at the forecast offices, there are plotted in a model grouping around the circle representing the station on the map the values of or symbolic indications of a number of weather elements. For all stations at least the barometric pressure (usually reduced to sea level), the air temperature, the present weather, the wind direction and speed or force, and the sky cover will be reported. In some countries many stations also give visibility, dew point or relative humidity, forms, amounts and movements of clouds at different levels, net amount of pressure change during the last three hours, the characteristics or the tendency in the pressure during the last three hours, and the amount of precipitation after the last observation. In reports made by ships at sea, the water temperature, the state of sea, position and motion of the ship are also reported.

An innumerable variety of charts could be constructed from such reports, but in practice only a few are made in addition to the standard charts containing the plotting and analysis of the complete surface reports; e.g., charts to show the change in pressure and the change in temperature since the previous chart or in the last 12 hr. or 24 hr. are often made. The analysis of the basic surface chart consists usually of isobars, fronts (q.v.), and air mass (q.v.) designations, and shadings or symbols to show where precipitation and fog are present.

Such maps are two-dimensional. To obtain a three-dimensional synchronous view of the atmosphere, it is customary, in regions where upper-air soundings are regularly made, to construct synoptic charts for several levels in the free atmosphere. Plotted on them, at the appropriate points where soundings are reported, are the values of the elements given by the soundings at that level, usually only pressure, temperature, humidity and wind. The levels selected for upper-air charts may be surfaces of constant height,

BY COURTESY OF THE NATIONAL GALLERY OF IRELAND

SYNGE: DRAWING BY JOHN BUTLER YEATS. 1905

constant pressure, or constant entropy. Constant-height surfaces of 5,000 ft., 10,000 ft., and 20,000 ft. mean sea level have been much used, but during the 1930s and the World War II years, after some experimentation with isentropic charts (*q.v.*), nearly all weather services gradually came to prefer constant-pressure charts; by 1945 they became practically internationally standard.

The World Meteorological Organization recommended that data for the following surfaces be evaluated from the soundings and broadcast: 1,000, 850, 700, 500, 300, and 200 millibars; and that analysis of the 700- and 500-millibar surfaces be made as a minimum. After World War II transmittal of sea-level and upper-air synoptic charts by means of facsimile (both telegraphic and radio) was developed, in the United States particularly.

With the advent of jet aircraft, analysis of much higher levels in the atmosphere was required. In this connection some forecasters draw lines of equal wind speed (isotachs, isokinetics) on the constant-pressure charts for 500-, 300-, 200-millibar and even higher surfaces, and charts showing the topography of the tropopause are prepared.

For tropical regions isobaric and constant-pressure charts have not proved very helpful for forecasting, and experiments indicated that streamline charts would be more successful, though the technique is difficult and weather reporting stations are still too sparse over most of the tropics.

In addition to the various types of charts already mentioned, which might be called the basic ones, it is customary in the larger forecast centres to prepare many auxiliary charts such as those showing the changes in height of a pressure surface with time, and those for the thickness and temperature of the layers between a lower and a higher constant-pressure surface. Some of the systems of analysis and forecasting under trial involve the preparation of many charts of an intermediate character representing the step-by-step computation of derived rather than observed factors; for example, in vorticity analysis and in some methods of numerical prediction.

Finally, there are the prognostic charts which represent the forecast patterns of pressure, height of pressure surfaces, or other elements (temperature, wind, etc.), for some future time.

Thus the total number of charts constructed in a large forecast central may amount to hundreds per day, and consume the services of a large staff working in shifts around the clock.

In connection with forecasting for longer periods of time than one or two days, it is desirable or necessary to construct mean synoptic charts which show averages of the elements over five days, a week, a month or more.

Over much of the Northern Hemisphere synoptic observations collected immediately by wire and radio permit maps to be made one, two, three, or four times a day as desired; in some countries maps can even be made for every hour. Large areas of the oceans, and particularly of the polar regions and Southern Hemisphere, have few observing stations or ships and hence cannot be synoptically charted in the detail required by weather forecasters. Methods of extrapolation of soundings or map patterns to heights above those reached by many of the soundings have been found expedient under certain conditions.

Synoptic charts are published daily by the leading national weather services. A remarkable series of historical weather maps for the Northern Hemisphere, one a day from Jan. 1, 1899, to June 30, 1939, compiled and analyzed by a uniform technique, were published by the U.S. government (Weather Bureau) during World War II and were resumed in 1946. The earliest weather charts were made well before 1835 by collecting synchronous weather reports by mail. The first telegraphic collection of synoptic reports and mapping thereof for forecasting was accomplished by Urbain J. J. Leverrier following the Crimean War. From about 1870 the leading nations have published charts each day along with the official forecasts. Simplified sea-level weather charts are published daily in many newspapers, posted in public places and discussed on television programs.

For the principles of analysis and use of synoptic charts in forecasting see AIR MASS; FRONTS; ISALLOBAR; ISENTROPIC CHART; WEATHER FORECASTING.

**BIBLIOGRAPHY.**—S. Petterssen, *Weather Analysis and Forecasting* (1940); V. P. Starr, *Basic Principles of Weather Forecasting* (1942); H. C. Willett, *Descriptive Meteorology*, 2nd ed (1959). (R. G. SE.)

**SYPHILIS:** see VENEREAL DISEASES.

**SYRACUSE** (Italian SIRACUSA; ancient SYRACUSAE), a city of southeastern Sicily and capital of Siracusa Province, lies on the Ionian coast 33 mi. (53 km.) SSE of Catania and includes the small island of Ortigia (Ortygia). Pop. (1961) 89,609. It was the chief Greek city of ancient Sicily.

On the mainland the town's modern districts project in long straight lines among orchards, flower gardens, and the stone quarries (*latomie*) which contrast with the narrow winding streets of the older part on Ortigia. The Porto Grande occupies a natural harbour and is separated from Porto Piccolo by Ortigia. Signs of the various conquests (Byzantine, Norman, Saracen, Swabian, Aragonese, Spanish) were destroyed in the 1693 earthquake, and medieval buildings that remained were camouflaged in 18th-century Baroque style. Excavations have unearthed monuments, dating from the 2nd to the 8th century and interesting for their copious epigraphs (see *Archaeology* below). Tourism, based mainly on archaeological interest, is highly developed. The locality is noted for soft limestone used in ornamentation. Industries include wine making, vegetable oil refining, cement and soap manufacture, salt processing, and fishing (shellfish).

**Architecture.**—The Byzantine architectural style is visible in three churches: the small basilica of S. Pietro, with 16th-century modifications; the Duomo (cathedral), built in the 7th century on the site of a Doric temple; and the Church of Sta. Lucia (12th-13th centuries, with 17th-century modifications), erected on the spot where St. Lucy, the city's patron saint, was martyred. The apse of Sta. Lucia contains "The Burial of St. Lucy" ascribed to the painter Michelangelo da Caravaggio. The small church of Sta. Maria dei Miracoli bears traces of both Gothic and Aragonese influence. The Porta Marina is a 15th-century gateway with Gothic and Catalan niches. The most important medieval building is the Castello Maniace, built by Frederick II in the 13th century with a square base and round corner towers. The Palazzo Bellomo (from the same period with later renovations) houses the Medieval Museum and the Art Gallery which has an "Annunciation" by Antonello da Messina. The 14th-century Margulense-Macciotta, Montalto, Chiamonte, and Abele palaces are rich in double- and triple-mullioned windows. The Lanza, Bellomo, Gargallo, and Banca d'Italia palaces represent 15th- and 16th-century Catalan and Gothic styles.

The influence of the Renaissance can be seen in the sculpture, the sarcophagi, and the stoups of the Gagini and Laurana schools. The Baroque element is visible in the Chapel of the Most Holy Sacrament, in the College Church, and in that of S. Benedetto after the earthquake it showed itself in the Beneventano, Borgia, Bongiovanni, and Rizzo palaces, in the Archbishop's Palace, and in the facade of the cathedral (1728-57).

In the cathedral are impressive sculptures and paintings, candelabra, chandeliers, and ciboria chiseled by artists working in gold in the second half of the 18th century. Modern buildings include the Post Office, University, Banca d'Italia, Banco di Sicilia, and Government Palace.

(M. T. A. N.)

**Archaeology.**—Ancient Syracuse had four districts: the island, Achradina (nearest the island), Tyche, and Neapolis. The island contains the remains of two Doric temples. The older, belonging probably to the early 6th century B.C., appears, from an inscription on the top step, to have been dedicated to Apollo, possibly also to Artemis. It was about 70 × 180 ft. (21 × 55 m.) and had 42 outer columns (6 columns along the ends and 17 along the sides), set close together and varying between 6 and 7 ft. wide at the base.

The other temple, which became the cathedral in A.D. 640 (it may have become a church even earlier), is to be dated after 480 B.C. It was of similar size (72 × 180 ft.) but had only 36 external columns (6 by 14). It is almost certainly the Temple of Athena. The site was previously occupied by buildings of the 7th and 6th centuries B.C., including a late 6th-century temple and a great sacrificial altar, which were destroyed to make room

LEONARD VON MATT

(TOP) THE REMAINS OF THE LARGEST GREEK THEATRE IN SICILY; (LEFT) WILD PAPYRUS PLANTS IN THE FOUNTAIN OF ARETHUSA NEAR THE WEST COAST OF SICILY; (RIGHT) SLAB OF PAINTED TERRA-COTTA (ABOUT 7TH-6TH CENTURY B.C.) where Epipolae narrows down to a ridge about 60 yd. wide, which is its only link with the hills to the west, still bears the ruins of a mighty fortress (Castello Eurialo), the most imposing, indeed, that has come down from the Greek period. There is no doubt that it was begun under Dionysius, although recent studies showed that the building belongs to more than one period; part of it may have been designed by Archimedes in the late 3rd century B.C. The total length of the works is about 440 yd. In front of the castle proper are three ditches, the innermost of which can be reached from the interior of the castle by a complicated system of underground passages. The front of the castle is formed by five massive towers; behind it are two walled courtyards, to the north of the easternmost of which is the well-guarded main entrance to the plateau of Epipolae (narrower minor entrances are to be seen on both the north and the south sides) connected by a long underground passage with the inner ditch in front of the castle proper. On the north side of Epipolae the cliffs are somewhat more abrupt; here the wall, similar to that on the south, is also traceable, but here it is apparently all of one period.

Remains of Greek and Roman private houses have been found, also several cemeteries, the most noteworthy being the Christian catacombs. Those near the church of Sta. Lucia are the most extensive (2nd century onward). Those near the 12th-century church of S. Giovanni are 4th-6th century, situated near an ancient temple, and contain the crypt of St. Marcellinus; the catacombs of

Vigna Cassia (3rd century onward) are also extensive.

for it. Their terra-cotta decorations were, however, carefully buried under the pavement of the space which surrounded it.

Near the west coast of the island is the famous spring of Arethusa (*g.v.*), where papyrus grows. According to the legend, the nymph Arethusa was changed into the spring by Artemis to deliver her from the pursuit of the river-god Alpheus (a river in the Peloponnese); and the spring, which was fresh until a medieval earthquake broke the barrier and let in the salt water, was supposed to be actually connected with the Alpheus. The large and well-arranged Museo Nazionale Archeologico contains important pre-Greek and Greek archaeological discoveries. On the landward side of the isthmus connecting the island with Achradina was the agora, in which remains of a colonnade of the Roman period have been found. To the west are the remains of the so-called "Roman gymnasium," probably a small theatre with a temple attached.

Both the island and Achradina had walls, but the most extensive defensive walls were those of Dionysius I, who built a wall about 12 mi. long around Epipolae, the plateau above Syracuse to the north. The southern wall of Epipolae, considerable remains of which exist, shows traces of different periods in its construction, and was probably often restored. It is built of rectangular blocks of limestone, generally quarried on the spot. Euryelus, the point

In Neapolis, the western quarter, public buildings predominate. The Temple of Apollo Temenites has almost entirely disappeared, but the rock-cut Greek theatre is still to be seen. It is the largest in Sicily, being nearly 455 ft. (139 m.) in diameter and having originally 59 rows of seats; the 12 lower tiers were originally covered with marble. Each of the nine *cunei* or blocks of seats bore a name; the inscriptions of four of them are still preserved on the rock, in honour of Zeus, King Hieron II, his wife Philistis, and Nereis, who married his son Gelon in 238 B.C. Of the stage nothing but cuttings in the rock and foundations are visible. The theatre was altered again in Roman times. It commands a splendid view over the Great Harbour, and it is often used for classical performances. Not far off to the southeast is the Roman amphitheatre; it is partly rock-cut and partly built. It is exceeded in size only by the Colosseum and the amphitheatres of Capua and Verona, measuring about 460 × 390 ft. (140 × 119 m.) over all: the arena is 227 × 129 ft. (69 × 39 m.). West of the amphitheatre are the foundations of the great altar erected by Hieron II, 653 × 74 ft. (199 × 23 m.). To the northwest of the theatre a winding road ascends through the rock; with Byzantine tomb chambers on each side of it; in this district are

hundreds of small niches cut in the rock, as a rule about 2 ft. square and a few inches deep, which contained inscriptions or reliefs relating to the cult of ancestors as heroes. In the cliffs below Epipolae are huge quarries, the famous Latomie of Syracuse; the Latomia del Paradiso contains the "Ear of Dionysius," a large artificial cave of unknown use and remarkable acoustic properties. Beginning about 1950, this whole quarter underwent thorough investigation and systematization.

Immediately outside Neapolis on the south the marshes of Lysimelia begin, which proved fatal to more than one besieging force. They are traversed by the Anapus (Anapo), with its tributary the Cyane (Ciane), the latter famous for the papyrus which grows wild in the stream. To the south of the Anapus is the hill Polichne, on which stood the Olympieum (Temple of Olympian Zeus), attributed to the early 6th century B.C. Its monolithic columns, of which two are still standing, are over 20 ft. high and 6 ft. in lower diameter: it is similar in plan to the Temple of Apollo but larger (about  $73 \times 203$  ft.). The hill was frequently occupied in attacks on Syracuse by the besieging force. From Punta Caderini (ancient Dascon), south of the Olympieum, the shore of the Great Harbour begins to rise, until the rocky Penisola della Maddalena (ancient Plemmyrium) is reached.

(E. A. F.; T. A.; X.)

**History.**—Syracuse was founded from Corinth, according to Thucydides, in the year after the first Greek Sicilian colony, Naxos (i.e., c. 733 B.C.). It was an excellent site. The offshore island of Ortigia was easily defended, there was a large arable plain opposite (between the shore and the higher ground of Epipolae to the north), and Syracuse had the best harbour in Sicily (as well as a smaller harbour north of the island). Thucydides says that Archias, the Corinthian founder, drove out Sicels from Ortigia, and remains of their huts and tombs have been found; the archaeological evidence shows that at the same time the colonists also settled on the mainland.

Syracuse slowly reaped the advantages of its position. It became the natural port of distribution for Corinthian goods; it extended its territorial control by the establishment of small settlements at Acrae (c. 663), Casmenae (c. 643), and Camarina (c. 598). Many of the Sicels in its territory were reduced to serfdom and worked the land for Syracusan masters; a few independent villages remained. In the second half of the 6th century Ortigia was joined to the mainland by a mole, coinage was introduced, and buildings became more ambitious. But it was the Deinomenid tyranny that marked the decisive stage in Syracuse's development.

**Gelon and Hieron.**—Hippocrates, tyrant of Gela (498–491), threatened the independence of Syracuse and other cities, and Syracuse was saved only by the joint intervention of Corinth and Corcyra and the cession of Camarina (previously depopulated by the Syracusans). In 485 the *Gamoroi*, or landowners (i.e., the descendants of the original settlers, who formed an aristocratic body), who had been expelled by the people and the Sicel serfs and had taken refuge at Casmenae, appealed to Hippocrates' successor Gelon (son of Deinomenes; hence "Deinomenid"), who took possession of Syracuse, without opposition, and made it the seat of his power. Gelon (q.v.) added to the population of Syracuse enfranchised mercenaries and the inhabitants of other cities conquered by him. His general rule was mild, and he won fame as the champion of the Greeks by his great victory over the Carthaginians at Himera (480). He is said to have been greeted as king; but he does not seem to have taken the title formally.

Gelon's brother and successor, Hieron (q.v.; 478–467/466), kept up the power of the city, and in 474 decisively defeated the Etruscans, who with the Carthaginians were the chief enemies of the western Greeks, at the Battle of Cumae. He won himself a name by his encouragement of poets, especially Aeschylus and Simonides, while his Pythian and Olympian victories inspired odes by Pindar and Bacchylides. But in his internal government he was suspicious, greedy, and cruel. After family disputes the power passed on his death to his brother Thrasybulus, who was driven out by a general rising (466). Syracuse thus became a democracy. Freedom was celebrated by a colossal statue and a yearly feast

of Zeus Eleutherius. But when the mercenaries and other new settlers were debarred from office new struggles arose. The mercenaries held Ortigia and Achradina (the part of the mainland city nearest the island). The people therefore walled in the suburb of Tyche to the north of Achradina. The mercenaries were eventually expelled (c. 460). Although there were attempts to reestablish tyranny, and an institution called *petalism*, like the Athenian ostracism (q.v.), was devised to guard against such dangers, democracy was not seriously threatened for more than 50 years, during which Syracuse's hegemony over Greek Sicily was never successfully challenged. There were also naval expeditions to the Etruscan coast, Elba, and Corsica about 453 B.C., and Diodorus Siculus mentions great military and naval preparations of Syracuse in 439.

**The Defeat of Athens.**—There is little trace, however, of these preparations during the Peloponnesian War when the Athenians sent a small force to Sicily in 427 to support the Ionian cities against Syracuse. The Athenian force, only 20 triremes, was able to hold its own, and the Syracusan navy was small and ineffective, but when Athens in 424 sent reinforcements the Syracusan statesman Hermocrates was able to persuade the Sicilian cities to bury their differences at the Conference of Gela. The Athenians had to withdraw, but the grievances of Segesta and Leontini (the latter of which had been depopulated by the Syracusans in 422) gave them the opportunity to return with a much larger force in 413. Hermocrates had great difficulty in making Syracuse realize the danger, and had the Athenians moved directly on Syracuse the city might have fallen. But the Athenian command was divided and decided first to win over allies. This delay and the subsequent recall of Alcibiades, who had inspired the expedition, saved Syracuse. The defensive measures, however, were inadequate, and the Athenians gained control both of the harbour and of Epipolae, the plateau north of the city. Syracuse was near to surrender when the Spartan Gylippus slipped through the Athenian lines with a small relief force. Gylippus put new spirit into the defense, the Athenians were driven from Epipolae, lost control of Plemmyrium commanding the entrance to the harbour, and were confined to the harbour and its shores. Reinforcements arrived in 413 from Athens under Demosthenes and Eurymedon, but a bold night attack on Epipolae failed. Demosthenes urged immediate withdrawal, but Nicias hesitated and an eclipse of the moon made him delay further. In a fierce naval struggle in the harbour the Athenians were defeated, and when they attempted to retreat by land it was too late. The Athenians and allies who escaped the massacre were imprisoned in the quarries; Nicias and Demosthenes were executed.

**Dionysius I.**—In the enthusiasm following this overwhelming victory Syracuse sent a small squadron under Hermocrates to fight for Sparta against Athens in the Aegean. But in his absence his political opponents, led by Diocles, seized power and introduced a more radical form of democracy. Hermocrates was exiled in 409; in 408/407 he was killed in an attempt to enter the city. With him was wounded Dionysius, who soon (supported by some men of rank, among them the historian Philistus), by accusing the generals engaged at Acragas in the war against Carthage, obtaining the restoration of exiles, and confiscating the property of the rich at Gela, secured his own election as sole general with special powers. He next procured from a military assembly at Leontini a vote of a bodyguard; he hired mercenaries and in 405 came back to Syracuse as tyrant and kept his power till his death (367). But he was almost overthrown in 405. When he was obliged to evacuate Gela and Camarina, his enemies in the army reached Syracuse before him, plundered his house, and assaulted his wife. Dionysius arrived by night and killed or expelled his enemies, who established themselves at Etna. In 397 or 396 Syracuse was besieged by the Carthaginians under Himilco, who took up his quarters at the Olympieum, but his troops in the marshes below suffered from disease, and a masterly combined attack by land and sea by Dionysius ended in Himilco's defeat and withdrawal. Peace with the Carthaginians confirmed Dionysius in the possession of Syracuse, and left it the one great Greek city of Sicily, which, however enslaved at home, was at least independent of Carthage.

During the long tyranny of Dionysius the city grew greatly in size, population, and grandeur. Syracuse absorbed the populations of Greek cities in Sicily and Italy which had fallen to the Carthaginians or to Dionysius. The fortifications of Syracuse were extended. The island (Ortygia) had its own separate defenses; Dionysius drove out the old inhabitants and turned the place into a barracks, living himself in the citadel. He included in his new mainland walls the whole plateau of Epipolae, with a strong fortress at Euryelus, its apex on the west. Syracuse was now the most splendid and the best fortified of all Greek cities. Its naval power, too, was vastly increased; the docks were enlarged, and 200 new warships were built. The fleet of Dionysius was the most powerful in the Mediterranean. Doubtless fear and hatred of Carthage urged the Syracusans to acquiesce in the enormous expenditure involved. Much, too, was done for the beauty of the city; several new temples were built, and gymnasia erected outside the walls.

**Dionysius' Successors.**—Under his son Dionysius the younger a reaction set in among the restless citizens of Syracuse. His uncle Dion (*q.v.*) was for a time his trusted political adviser. Dion's idea seems to have been to make Dionysius something like a constitutional sovereign, and with this in view he invited Plato to Syracuse. But Philistus and other followers of Dionysius were opposed to any kind of liberal reform, and the result was the banishment of Dion from Sicily. In 357 Dion returned and besieged Dionysius in Ortygia; though he escaped, there was much bloodshed and destruction before Ortygia surrendered. Dion tried to establish aristocratic government but was assassinated in 354.

In the confusion that followed, Dionysius returned, and Sicily was again menaced by Carthage. Syracuse asked help from the mother-city, Corinth; and Timoleon (*q.v.*), who was sent out, drove Dionysius from Ortygia and recovered Syracuse. He then decisively defeated the Carthaginians and made a peace settlement in which they were confined to the smaller half of Sicily west of the Halycus (modern Platani) River. From 343 to 337 he was supreme at Syracuse, with the goodwill of the citizens. The tyrants' citadel on Ortygia was demolished. Syracuse, with an influx of many new colonists from Greece, Sicily, and Italy, prospered once more. Timoleon retired in 337 and soon died. After his death a splendid monument, with porticoes and gymnasia surrounding it, known as the Timoleonteum, was raised to honour his memory.

At some date before 317 another revolution at Syracuse apparently transferred the government to an oligarchy of 600 leading citizens. In 317 Agathocles (*q.v.*), with a force of Sicels from Morgantina and exiles from the Greek cities, backed up by the Carthaginian Hamilcar, became tyrant of the city. When he was hard pressed by the Carthaginians, he took the bold step of leading an expedition to Africa in 310. His campaign was at first successful and relieved the pressure on Syracuse, but his fortunes changed, and in the winter of 307/306 he was forced to withdraw finally. He was able, however, to secure an honourable peace with Carthage and to confirm Syracusan influence over eastern Sicily and parts of south Italy. Under his strong government Syracuse was free from faction, the fortifications were restored, and new public buildings erected. After his death in 289 came another period of revolution and despotism; and but for the brief intervention of Pyrrhus, king of Epirus, in 278–276, Syracuse, and all Sicily, would have fallen to the Carthaginians.

A better time began under Hieron II, who had fought under Pyrrhus and who rose from general to tyrant (king, as he soon came to be called). During his reign (*c.* 270–216/215) Syracuse seems to have grown greatly in wealth and population. Hieron's rule was kindly and enlightened, combining good order with a fair share of liberty and self-government. His financial legislation was careful and considerate; his regulations for the customs and the corn (grain) tithes were accepted and maintained under the Roman government. He encouraged the poet Theocritus and employed the mathematician and engineer Archimedes (*qq.v.*), both born in Syracuse. It was a time, too, for great public works. After a Roman attack on Syracuse (263) Hieron became a firm ally of Rome against Carthage (*see* PUNIC WARS).

**Capture by the Romans.**—Hieronymus, the grandson of Hieron, allied himself with Carthage, but he soon fell in a conspiracy (214). There was a fierce popular outbreak, and Hieron's family was murdered; the Carthaginian party finally got the upper hand. M. Claudius Marcellus was then in command of the Roman army in Sicily, and he threatened the Syracusans with attack unless they expelled Epicydes and Hippocrates, the leading anti-Romans. These two escaped from Leontini when Marcellus promptly stormed it. This sack roused the feeling of the Syracusans against any negotiations with the Roman general, and, electing Epicydes and Hippocrates generals, they closed their gates on him. Marcellus, after an unsuccessful attempt to negotiate, began the siege (213 B.C.), establishing a camp on Polichne, where the old Olympieum stood; but he made his chief assault on the northern wall by land and on Achradina by sea. The city was defended by a large garrison and by the ingenious contrivances of Archimedes, whose engines of war dealt havoc among the Roman ships and frustrated the attack on the fortifications on the northern slopes of Epipolae. Marcellus was obliged to besiege the city; at last, in 212, information was given him that the Syracusans were celebrating a great festival of Artemis. Making use of this opportunity, he forced the Hexapylon entrance (modern Scala Greca) by night and established himself on the heights of Epipolae and in Neapolis and Tyche. The strong fortress of Euryelus was isolated and soon had to surrender. Achradina and the island still held out; a Carthaginian fleet was moored off Achradina and Carthaginian troops were encamped near Polichne. But disease broke out in both armies. The Carthaginian ships sailed away; on their way back to Syracuse with supplies they were driven away by adverse winds and a Roman fleet. Achradina and the island still held out under the Syracusan mercenaries, till one of their officers, a Spaniard, betrayed them to the Romans (211). Marcellus gave the city up to plunder, and many of its art treasures were taken to Rome. Archimedes perished in the confusion of the sack.

(E. A. F.; T. A.; R. ME.)

Syracuse became the Roman governor's residence. Cicero has many references to it as a centre of Greek art and culture, and Augustus established a colony there. Frankish pirates plundered the city *c.* A.D. 280.

Legend attributed the beginning (certainly early) of Christianity at Syracuse to the three days St. Paul spent there on his way to Rome. The first bishop was said to have been Marcianus; Lucy, patron saint of Syracuse, was martyred *c.* 305 under Diocletian.

The Byzantine emperor Constans II attempted to make Syracuse his capital (663), but was assassinated there in 668. The Arabs took it in 878; Palermo became the leading city in Sicily, though Syracuse was always an important port. It was briefly regained for the Byzantine emperor by George Maniakes (1038–40), and it was the amir of Syracuse, Muhammad ibn Timnah, who encouraged the Normans to invade Sicily (1060). Under the Aragonese, Syracuse became the seat of the governor of the Camera Reginale, the domain of the queen of Sicily.

An unsuccessful revolt against the Bourbon government in 1837 led to Syracuse's demotion from provincial capital in favour of Noto (until 1865). During World War II it was heavily bombed by the Allies, particularly the port area.

**SIRACUSA PROVINCE.** The province (area 814 sq.mi. [2,109 sq.km.]; pop. [1961] 345,867) stretches across the hilly slopes of Monti Iblei and as far as the plains of Catania and Lentini. The economy is principally agricultural. The fertile land produces maize (corn), cereals, vegetables, vines, olives, citrus fruit, carobs, nuts, almonds, cotton, and fodder. There are small numbers of livestock. Commercial activities include food processing, canning, milling, salt extraction, the distillation of orange-blossom and aromatic herbs, and the production of olive oil and wine (muscatel). The province is crossed by the rail routes Catania-Syracuse-Pozzallo and Syracuse-Ragusa. Its most important towns are Pizzolungo (military base and port), Avola, Floridia, Lentini, Noto, Pachino, and Palazzolo Acreide, the modern successor to ancient Akrae with its Greek and Roman ruins.

**SYRACUSE**, a city of New York, U.S., and the seat of Onondaga county, is midway between Albany and Buffalo, at the south end of Lake Onondaga (5 mi. long). It is the central city of the Syracuse standard metropolitan statistical area, which encompasses Madison, Onondaga and Oswego counties. Syracuse itself has lost population to the metropolitan area; in 1960 the population of the city was 216,038, as compared with 220,583 in 1950. The metropolitan area by contrast had a population of 563,781 in 1960, a 21.2% increase since 1950. The growth is spreading north to Liverpool, west to Auburn and east to Chittenango, reaching toward Oneida, Rome and Utica to form a single great central New York urbanized region. (For comparative population figures see table in NEW YORK: *Population*.)

**History.**—The site of Syracuse was the home of the Onondagas and the capital of the Iroquois federation called the Five (later Six) Nations, whose founding father was Hiawatha. Known also as "The Long House" or "People of Many Fires," the Iroquois formed a chain of nations, beginning with the Mohawks at the easternmost point and linking the Oneidas, Onondagas, Cayugas and Senecas on the west (see also IROQUOIS). The site was visited by the explorers Samuel de Champlain in 1615 and Pierre Esprit, sieur de Radisson, in 1651 (while a captive of the Mohawks) and by Simon Le Moyne, a Jesuit missionary, in 1654. At the site was a spring from which the Indians would not drink because they believed a demon lived in it, giving the water an evil smell; Le Moyne discovered that it was a fountain of salt brine. In 1655 a mission was founded by Fathers Joseph Chaumonot and Claude Dablon, and the next year a military post was founded near the present village of Liverpool (5 mi. NW of Syracuse); both were abandoned in 1658 because of the hostility of the Mohawks, but the mission was resumed in 1668 and continued through the century.

The first white settler at Syracuse was Ephraim Webster, who established a trading post there in 1786. In 1788 Asa Danforth, who came to be called "the father of Onondaga county," built a sawmill and a gristmill and organized the militia. Also in that year the state undertook by treaty with the Onondagas to manage the salt springs; in 1795 it acquired title to the springs and 10 sq.mi. of surrounding land in return for \$1,000 in cash and promise of an annual rental of \$700 and 150 bu. of salt. In 1797 the state began leasing the salt lands on a royalty basis. Three villages soon sprang up around the southern end of the lake: Webster's Landing and Salina in 1797 and Geddes (founded by James Geddes, the first manufacturer of salt on a large scale) in 1803. The landing was known by several names in succession until 1820, when a post office was established and the name of Syracuse was adopted, after the ancient Greek city in Sicily. Syracuse was incorporated as a village in 1825, became the county seat in 1827 and, absorbing Salina, was chartered as a city in 1847. From time to time various annexations of contiguous territory were made, including the village of Geddes in 1886. The Onondaga Indian reservation is located 6 mi. S of the city.

**Government.**—Syracuse has a mayor and council form of government. Because of the development of the metropolitan area, especially Onondaga county, local government is tending more toward a county or metropolitan form; for example, by 1950 it was evident that the supply of water then available was insufficient for further industrial development, and in that year the Onondaga County Water authority was created to attack the problem from an area standpoint. The city and county per capita costs of government are average for the cities and counties of upstate New York, as are the property tax rates. The city has a sales tax and is virtually debt free.

**Commerce, Industry and Transportation.**—The salt industry provided the original economic foundation of the city, as well as the source of its first private fortunes; Syracuse supplied most of the salt for the United States until 1870. Since then, however, the metropolitan area has developed into a manufacturing centre of considerable importance. The principal products are machinery, metal products, food, paper products and chinaware. It is the wholesale trade centre for the central New York region, rivalled only by Buffalo at one side of the state and Albany at the other. Syracuse is situated at the crossroads of central New York and is well served by highways and railroads. Hancock airport is supplemented by numerous other public and private airports. The State Barge canal is within easy reach; four oil pipelines complete the transportation system.

**Education and Cultural Activities.**—Syracuse is an outstanding educational centre, led by Syracuse University, a private coeducational institution founded in 1870 by the Methodist Church. Its colleges and schools offer facilities for graduate, professional and adult education; among them are the Maxwell Graduate School of Citizenship and Public Affairs, the College of Forestry (a unit of the State University of New York) and a branch college in Utica. Le Moyne, a Roman Catholic coeducational college, was founded in 1946. Nearby are two state university colleges of education, at Cortland and Oswego, and the Auburn Community College, a two-year institute. There are numerous musical and dramatic groups, including summer theatres at nearby Skaneateles and Fayetteville, the Everson Museum of Art, the Lowe Art Centre and the Barrows Art Gallery (Skaneateles). The Salt Museum near Syracuse and Rail City near Oswego feature the history of those industries. The fair grounds, where state fairs have been held since 1890, are at the western edge of the city.

**Recreation.**—The recreation opportunities of the city and area include many fine places for hunting, camping, boating, swimming and fishing; eight state parks in the Finger Lakes region; Lakes Ontario, Onondaga and Oneida; and the Adirondack Mountains.

(V. C. C.)

**SYR-DAR'YA** (ancient JAXARTES), a river of the U.S.S.R. and the longest river in Central Asia, which flows into the Aral Sea. It is formed by the confluence, in the eastern part of the Fergana Valley, of the Naryn and Tar (Kara-Dar'ya) rivers which have their source in the Tien Shan (Tyan' Shan') Mountains. The length of the Syr-Dar'ya is approximately 1,370 mi. (2,200 km.) from the confluence of the Naryn and Tar, and 1,800 mi. (2,900 km.) from the source of the Naryn. Its water capacity is slightly less than that of the Amu-Dar'ya (q.v.), and its total drainage area is 178,000 sq.mi. (462,000 sq.km.).

The Syr-Dar'ya waters the Fergana Valley through which it flows between mostly sandy banks. Until they reach that valley, the Naryn and Tar are mountain streams. The Syr-Dar'ya's main tributaries reach it in the Fergana Valley: on the right bank Kassansay, Gavasay, and Chada (Chadak-Say); on the left Isfayram, Shakhimardan, Sokh, Isfara, Khodzhbakirgan, and Aksu. None of these bring any water to the main stream as they lose it in irrigation, soakage, and evaporation. On leaving the Fergana Valley the river cuts through the Farkhad Mountains, forming the Begovat Rapids, where the Farkhad hydroelectric station was completed in 1948. There, on the right bank, are the headworks of the Dal'verzin Irrigation System, and lower down, on the left bank, those of the north Golodnaya Steppe System. The river flows on through steep wooded banks, receiving on the right the tributaries Angren, Chirchik, and Keles, which feed a complex irrigation system. (See also FERGAN VALLEY.) The last important right-bank tributary is the Arys'. Below these tributaries the river crosses the eastern edge of the Kyzylkum Desert, where the banks and the bed of the river are formed from slightly indented loess-clay formations. The low steep banks are usually flooded at high water. The course here is meandering and indeterminate and often changes, forming creeks which may be lost in the sand. This is particularly so near and below the town of Kzyl-Orda. There the river is joined on the right bank by the large tributary Karaozek. Of the many lakes in the valley the largest, Birkazan and Klemzhaygan, contain fresh water. In its

lower course the river passes over silt of its own creation and is thus raised above the surrounding country, causing frequent flooding in spring and summer. At its mouth it forms a small delta with several creeks, lakes, and marshes which are filled up at high water.

The Syr-Dar'ya derives most of its water from snow, and to a minor extent from ice and rain. The high-water period lasts for about five to six months, from March or April to August or September. The level is at its highest in June. The lower reaches of the river generally freeze in December, the ice breaking up in March; the middle reaches freeze only occasionally. In the upper course, in the Fergana Valley, the river freezes only in places for short periods. The Syr-Dar'ya is navigable within the limits of the Kzyl-Orda Oblast' of the Kazakh Soviet Socialist Republic, and above that in a few isolated sectors. The main towns on the river are Leninabad, Begovat, Kzyl-Orda, and Kazalinsk.

(G. E. Wr.)

**SYRIA (As Suriyah).** Modern Syria, known as the SYRIAN ARAB REPUBLIC (Al Jumhuriyah al 'Arabiyyah as Suriyah), is bordered on the north by Turkey, on the east and southeast by Iraq, on the south by Jordan and Israel, on the southwest by Lebanon, and on the northwest by the Mediterranean Sea. Area 71,498 sq.mi. (185,180 sq.km.). The present territory does not coincide with ancient Syria, which was the fertile strip between the eastern Mediterranean coast and the desert of northern Arabia. The modern Arab nationalist concept of Greater Syria extends this territory to the Euphrates, and thus includes Israel, Lebanon, and Jordan. Syria has been included in all the great empires of the eastern Mediterranean and southwest Asia—Egyptian, Hittite, Babylonian, Assyrian, Persian, Hellenistic, Roman, Arab, and Ottoman. After World War I, as part of the Levant States, it was included with Lebanon in the French Mandate from the League of Nations, and its present largely artificial boundaries were demarcated by 1925. In 1939 the sanjak of Alexandretta (Hatay) was ceded by France to Turkey. The Free French declared Syria independent in 1941, and the Syrian Republic was a founder member of the Arab League. French troops withdrew finally in 1946. In February 1958 Syria federated with Egypt to form the United Arab Republic (*q.v.*) but seceded from the union in September 1961. The capital is Damascus.

### I. PHYSICAL GEOGRAPHY

**1. Geology.**—Syria comprises the northern fringe of the stable Archean platform of Arabia, generally overlain by younger sedimentaries. In the west the latter are faulted and folded along northeast-to-southwest and north-to-south axes, which continue the structural features found in Israel, Jordan, and Lebanon. In western Syria the exposed rocks are mainly of Jurassic and Cretaceous age, but they are locally overlain by Tertiary sediments, Pleistocene and Recent alluvium or lava flows. In the Hawran (Hauran) and Jabal al Duruz (Jabal Druze or Jebel Druze) there are extensive basalt outcrops with Recent volcanic craters. The centre and east of the country is mainly composed of thin sheets of Tertiary limestones and marls, overlying undisturbed Secondary rocks on the Archean platform. Jabal Ansariyah (Jebel Ansarieh) in the northwest is an anticline of Jurassic and Cretaceous rocks; to the east lies the partly downfaulted trough of Al Ghab. Along the Lebanese border Mt. Hermon (*q.v.*; Jabal ash Shaykh) and the Anti-Lebanon (Jabal al Sharqi) are similar upfolds of Jurassic and Cretaceous rocks. A series of minor folds extends northeastward across the Syrian Desert (Badiyat ash Sham) to Palmyra (Tadmor) and the Euphrates, beyond which their direction becomes west to east, parallel to the Anti-Taurus ranges in Turkey. In the extreme northwest there are some metamorphic rocks in the Kurd Dagh and Jabal Qusayr (Jebel Kuseir), a result of Cretaceous folding associated with the Anti-Taurus uplift and the Kyrenia Range of Cyprus.

**2. Relief and Drainage.**—The western folded region, together with the Jabal al Duruz, is mountainous. The remainder of the country is an upland plain sloping gently northward and eastward; to the south and east this plain is a stony, gravelly desert, but in the north and west it is a steppe region.

The coastal plain is narrow and interrupted by spurs of the Jabal Ansariyah, but south of Tartus it widens into the Plain of 'Akkar, through which runs the border with Lebanon. The coast is alternately one of sandy bays and rocky headlands with low cliffs. Jabal Ansariyah has an average width of 20 mi. (30 km.), and is highest in the north 5,125 ft. (1,562 m.). Its average height declines from 3,000 ft. (900 m.) to 2,000 ft. southward. Immediately east of Jabal Ansariyah is Al Ghab. This trough is about 40 mi. (65 km.) long, drained by the north-flowing Orontes River (Nahr al 'Asi) which has there created a large marsh due to a basalt sill impeding the river's flow. Between Homs and Hamah the Upper Orontes cuts a meandering gorge in the steppe plateau.

South of Homs the western border follows the crest of the Anti-Lebanon Range. The main ridge has a maximum height of 8,860 ft. (2,700 m.) near Zabadani, and its mean height is between 6,000–7,000 ft. (1,800 and 2,100 m.). Mt. Hermon (9,232 ft. [2,814 m.]) is a single whale-backed ridge. The two ridges are separated by a pass, the Zabadani Saddle, which carries the Damascus-Beirut road and railway.

The south-central section of the Syrian Desert, commonly called Al Hamad, is not featureless; three minor mountain ridges strike northeast from Damascus toward Palmyra. Similar ridges (*e.g.*, Jabal Bil 'as and Jabal al Bishri) continue to the Euphrates, and beyond (*e.g.*, Jabal 'Abd al 'Aziz). The lava region of the Hawran culminates in the extinct volcanic cone of Jabal al Duruz at 5,905 ft. (1,800 m.). Al Jazirah region stretches east of the Euphrates into Iraq, reaching the Tigris between Cizre and Fayshkabur (a width of about 25 mi.).

The Euphrates (*q.v.*), the largest river of Syria, rises in the highlands of eastern Turkey, enters Syria at Jarabulus (Jerablus) and flows south and then southeast to Abu Kamal near the Iraq border. Its only important left-bank tributaries, the Belikh and Khabur (Khabor or Habur), flow south from Turkey; its right bank tributaries (*wadis*) are seasonal. The Orontes (*q.v.*) rises

MAJOR TOWNS AND RAIL COMMUNICATIONS OF SYRIA

in Lebanon, drains the northern Bekaa (Al Biqa'), the western steppes, and Al Ghab before entering Turkey. The western Jabal al Duruz and the Hawran are drained by the Nahr al Yarmuk, a tributary of the Jordan River (Nahr al Urdunn). The Yarmuk Gorge forms the border in the southwest. The Zabadani Saddle and eastern Mt. Hermon are drained by the Barada (biblical Abana) and the A'waj (Pharpar), which water the fertile oasis of Damascus (Ghutah). The other rivers draining the mountains eastward are seasonal or lose their waters in salt marshes and mud flats in the desert. Several small perennial streams flow in steep gorges on the western slopes of Jabal Ansariyah to the Mediterranean; the largest of these are the northern and southern Nahr al Kabir (ancient Eleutherus).

**3. Climate.**—The coast and the western mountains have a Mediterranean climate with a long dry season from May to October. In the extreme northwest there is some light summer rain. On the coast, summers are hot, with mean daily maxima of 29° C (84° F), winters mild, with mean daily minima of 10° C (50° F). Only above 5,000 ft. (1,500 m.) is found relatively cool summer weather. Inland the climate becomes arid, with colder winters and hotter summers. Damascus and Aleppo have mean daily maxima of 35 to 38° C (95–100° F) in summer and mean daily minima of 1 to 3° (34–37°) in winter. In the desert, at Palmyra and Dayr az Zawr, mean daily maxima in summer reach 40.5 to 43° (105–109°) with extremes of up to 50° (122°). Snow is liable to occur each winter away from the coast, and frosts are common.

The coast and western mountains receive 30–50 in. (760 to 1,270 mm.) rainfall annually. The fall decreases rapidly eastward in lee of the mountains; the steppe, extending from the Hawran northward through Damascus, Homs, and Aleppo, and thence eastward to Al Jazirah, receives 10–20 in. (250 to 500 mm.) per year. The steppe region is widest in the Hawran and east of Homs, where gaps in the coastal ranges extend humid conditions farther east. Thus Jabal al Duruz receives more than 500 mm. In the desert, or Al Hamad, rainfall decreases to less than 130 mm. per year. Rainfall is variable from year to year, particularly in the spring and autumn months. This variability, combined with hot winds (khamsin) from east and southeast in early summer and autumn, makes cultivation without irrigation hazardous when there is less than 15 in. (380 mm.) mean annual rainfall and virtually impossible when it is less than 200 mm.

**4. Vegetation.**—There is much cultivation in the coastal plain and in Jabal Ansariyah, where the natural vegetation has been largely destroyed. *Garrigue*, degenerate Mediterranean scrub, and

*maquis* cover many slopes. In the north there are some forests of Aleppo pine and isolated thin stands of Sessile and Syrian oak. Olive, carob, and fruit trees are common. The Anti-Lebanon and Mt. Hermon are mainly bare save for some scrub and ephemeral wild flowers, including alpine species; but the valleys bear poplar, willow, and alder. Much of the Hawran and the central and northern steppe in Al Jazirah have been cultivated, but a profusion of Mediterranean and Turanian shrubs and plants occur. Syria lies in the zone of contact between three major plant association regions—Mediterranean, Irano-Turanian, and Saharo-Sindian. The Jabal al Duruz bears kermes oak and *maquis*. Al Hamad supports only xerophytes and halophytes except along the Euphrates and its tributaries, where marsh vegetation and some trees grow.

**5. Animal Life.**—In the Anti-Lebanon and Jabal Ansariyah wolves are occasionally found; antelope and gazelle inhabit Al Hamad. Other mammals of the country include deer, wild cat, ichneumon, porcupine, hedgehog, squirrel, marten, ermine, otter, dormouse, rat, and hare. Vipers, lizards, and chameleons are common in the desert. Water fowl, including flamingoes and pelicans, abound in the lakes and marshes. Many migrating birds pause on their way north and south. Eagles, buzzards, kites, and falcons frequent the mountains. Among the insects, mosquitoes, sandflies, grasshoppers, and occasionally locusts are harmful.

(C. G. Sm.)

## II. HISTORY

The earliest prehistoric remains of human habitation found in Syria and Palestine (stone implements, with bones of elephant and horse) are of the Middle Paleolithic period. In the next stage are remains of rhinoceros and of men who are classified as intermediate between Neanderthal and modern types. The Mesolithic Age is best represented by the Natufian culture, which is spread along, and some distance behind, the coast of the Levant. The Natufians supported life by fishing, hunting, and gathering the grains which, in their wild state, were indigenous to the country. This condition was gradually superseded by cultivation of crops, accompanied by the use of pottery, and to these was afterward added metal and metalworking, with manufacture of tools. Primitive pottery has been found in the north of Palestine and at Jericho, possibly dating from as early as c. 5000 B.C. The beginnings of metallurgy are later but may go back to about the mid-4th millennium. This art seems to have been introduced by a more northern race settling among a population of Mediterranean stock, who may have been the ancestors of the Semites. From this amalgam evolved the people who first built towns, which were characteristic of the Early Bronze Age. See further PALESTINE: *Archaeological Exploration and Prehistory and History*.

### A. EARLY HISTORY

History begins with the invention of writing, which took place in southern Babylonia perhaps c. 3000 B.C., the script being an original picture-character which developed later into cuneiform. An early Sumerian ruler of the city of Erech, named Lugalzagesi, recorded his triumphal progress from the lower sea to the upper (the Mediterranean). Immediately after this, Syria appeared as the origin of a great migration of Semitic invaders into Babylonia by way of the Euphrates, the first of several such movements which are never traceable farther back than Syria. These first intruders have been given the name of Akkadians from their leader, Sargon (q.v.) of Agade or Akkad. According to legend, he was born obscurely on the upper Euphrates, launched on the river in a reed basket, and adopted in Babylonia, where he became the greatest conqueror and the most famous name in Babylonian history. From his new city of Agade he marched back up the Euphrates to the "cedar mountain" (the Amanus) and far beyond, if the various sources may be trusted.

It is probable that Sargon and his equally famous grandson Naramsin (c. 2275 B.C.) ruled effectively over the whole of Syria, to which they doubtless introduced the Sumerian writing that they had learned and adapted to their Semitic language in Babylonia. But the dynasty of Akkad was soon overthrown at its centre and superseded by the dynasties first of Gutti and then of Ur. Nothing

certain is known about the authority (if any) that the kings of Ur exercised in Syria, so far away from their capital. The end of their dynasty, however, was brought about chiefly by the pressure of a new Semitic migration from Syria, this time of the Amorites (i.e., the westerners), as they were called in Babylonia. (See AMORITES.) Their invasion began before 2000 B.C., and before the 18th century B.C. they had covered both Syria and Mesopotamia with a multitude of small principalities and cities, mostly governed by rulers bearing some name characteristic of the Semitic dialect that the Amorites spoke. The period of Amorite ascendancy is vividly mirrored in the Mari letters, a great archive of royal correspondence found at the site of Mari, near the modern frontier with Iraq. They treat of the wars and general affairs of a multitude of states extending from northern Palestine to the upper Tigris. Among the principal figures mentioned are the celebrated lawgiver Hammurabi of Babylon (himself an Amorite) and a king of Aleppo of whom little is yet known. Part of his kingdom was the city of Alalakh, on the Orontes near what was later Antioch. This has yielded to excavation records both of the Amorite period and of a later age.

At about the same time (later in the 18th century B.C.) there began from Syria a movement of people in the opposite direction. This resulted in the Hyksos invasion of Egypt, which was subject to this foreign domination for about 150 years. The mixed multitude of the Hyksos certainly included Hurrians (*q.v.*), who, not being Aryans themselves, were under the rule and influence of Aryans and learned from them the use of light chariots and horses in warfare, which they introduced into Egypt, Syria, and Mesopotamia. The Hurrians established the kingdom of Mitanni, with its centre east of the Euphrates, and this was for long the dominant power in Syria, reaching its height in the 15th century B.C.

But other nations were growing at the same time, and in the 14th century Syria was the arena in which at least four great competitors contended. The Hurrians were first in possession, and they maintained friendly relations with Egypt, which, after expelling the Hyksos, had established a vast sphere of influence (it was scarcely an empire) in Palestine and Syria, under the kings of the 18th dynasty. Third of the powers disputing Syria in the 14th century were the Hittites (*q.v.*), who finally, under their greatest warrior, Suppiluliumas (*c.* 1350 B.C.), not only defeated the kingdom of Mitanni but established a firm dominion of their own in northern Syria with its principal centres at Aleppo and Carchemish. Fourth was the rising kingdom of Assyria, which became a serious contender in the reign of Ashur-uballit I. Indeed a fifth actor also appeared on the scene, the king of Babylon, but he was too distant and impotent to affect the issue.

This was the period of the Amarna letters (see TELL EL AMARNA), which vividly illustrate the decline of Egyptian influence in Syria, especially under Ikhnaton, the distrust or duplicity of local governors, and the rivalry of the aforesaid powers. Egyptians and Hittites continued their struggle into the 13th century, but even the Battle of Kadesh, which Ramses II so boastfully claimed to have won (*c.* 1300 B.C.), led to no more than a treaty maintaining the equal balance. Assyria had already swept away the remains of Mitanni but itself soon fell into decline, and the Hittites were not long afterward driven from their centre in Asia Minor by the migration of "peoples of the sea," western invaders from the isles of the Aegean and from Europe (see SEA PEOPLES). These immigrants then marched down the coast of the Levant and threatened Egypt but were repulsed by Ramses III (*c.* 1190 B.C.).

While all the neighbouring states had failed to establish a lasting ascendancy in Syria, actual possession was assumed gradually by a people without sufficient cohesion to appear as a power at all. Various documents of the 14th century mention the Akhlame, who were forerunners of another vast movement of Semitic tribes called generically Aramaeans (*q.v.*). By the end of the 13th century these had covered with their small and loose principalities the whole of central and northern Syria. The Assyrians, however, were able to guard their homeland from this penetration, and henceforth much of the warfare of Assyrian kings was to be a mixture of aggression and defense aimed at the Aramaean states of Syria. At about the same time as the Aramaean invasion, the exodus of

Israelite tribes from Egypt was proceeding. As the Israelites toward the end of the 11th century established a kingdom centred upon Jerusalem, the Aramaeans set up their principal kingdom at Damascus, and the wars between kings of Judah or of Israel and kings of Aram make up much of Old Testament history.

But the most formidable enemies of the Aramaeans and often of the Hebrews were the great military kings of the Assyrians. After a premature Assyrian incursion under Tiglath-pileser I early in the 11th century B.C., the real contest was reserved for the 9th and the 8th, during which the Assyrian empire was established over the west, though destined to be short-lived. At the Battle of Karkar in 853 B.C. Shalmaneser III of Assyria was opposed by Bar-Hadad I (Hebrew, Ben-Hadad; throne name, Hadadezer; Akkadian, Adad-idri) of Damascus, Ahab of Israel, and 12 vassal monarchs. In 732 Damascus, the Syrian capital, was at length captured by Tiglath-pileser III. But campaigns against the Aramaeans and Anatolians of northern Syria (called "Hatti-land") had to be undertaken by the Assyrians until almost the end of the Assyrian empire. Culturally, the most important achievement of the Aramaeans was the bringing of the alphabet into general use for public and private business.

Before the close of the 8th century B.C. began a massive southward movement of people, partly of Aryan stock, from the north and west. Pressure of these upon the Assyrian dominions and homeland became ever more severe, and they deeply affected Syria also; and in the 7th century came the invasion of the Cimmerians, followed by the Scythians. To these and to the Medes Assyria finally succumbed with the fall of Nineveh in 612 B.C. Nebuchadnezzar, when crown prince of Babylon, finally defeated the attempted rescue of Assyria by Necho II, king of Egypt, and annihilated his army at Carchemish in 605 B.C. In 597 he captured Jerusalem and carried its people into exile. Thereafter Syria was for half a century under the rule of Nebuchadnezzar's successors on the throne of Babylon.

But another and greater power, the Persians, then came to the fore. Under the leadership of Cyrus they subverted the rule of the Medes and assumed their empire, extending their conquests into Asia Minor, and then came to a final collision with Babylon, which Cyrus occupied in 539 B.C. He returned all the gods of Babylonia to their own places, and sent back the exiled Jewish community to Jerusalem, encouraging them to rebuild their Temple. In Darius I's great organization of the Persian dominions, Syria, with Palestine and Cyprus, was the fifth satrapy, bearing the name of "Across the River" (i.e., the Euphrates), with tribute fixed at 350 talents of silver. Damascus and the Phoenician cities were still the chief centres of Syria under the Persians, and in Sidon was the core of the Phoenician revolt against Artaxerxes III, which ended with the destruction of that city in 345 B.C. But by this time the end of the Persian domination was at hand, and the Macedonians under Alexander III the Great were about to bring the whole Near East under Greek rule and influence.

Alexander invaded Asia Minor in 334 B.C., and his victory over the Persians at Issus in 333 was followed by the capture and enslavement of Tyre and Gaza. With the Battle of Gaugamela and the destruction of Persepolis the downfall of Persia was completed.

See further PHOENICIA; PERSIAN HISTORY; DAMASCUS; BABYLONIA AND ASSYRIA: *History*. (C. J. G.)

## B. HELLENISTIC AND ROMAN PERIODS

1. **Hellenistic Age.**—After Alexander's death in 323 B.C. his marshals contended for control of the country, until after Ipsus (301) Seleucus I Nicator gained the northern part and Ptolemy I Lagus gained the southern (Coele-Syria). This partition between the Seleucids and Ptolemies was maintained for 100 years despite intermittent Syrian wars during the 3rd century (see SELEUCID DYNASTY). Their administrative methods varied. In the south the Ptolemies respected the existing autonomous cities, imposed a bureaucratic system on the rest of the country, and established no colonies. The Seleucids divided the north into four satrapies, which embraced the cities, and founded many cities and military colonies—among them Antioch, Seleucia Pieria, Apamea, and Laodicea (*qq.v.*)—drawing on European settlers. Republics re-

placed kings in the Phoenician coastal cities of Tyre (274 B.C.), Sidon, Byblus, and Aradus. Further political and cultural changes followed.

In 200 B.C. (or perhaps as late as 198) Antiochus III the Great defeated Ptolemy V at Panium and secured control of southern Syria, where he introduced the satrapal system. His subsequent defeat by the Romans at Magnesia (December 190 or January 189), however, resulted in the loss of both his territory in Asia Minor and his prestige, thereby fundamentally weakening the Seleucid empire, which ceased to be a Mediterranean power. Antiochus IV Epiphanes (175–163) stimulated the spread of Greek culture and political ideas in Syria by a policy of urbanization; increased city organization and municipal autonomy involved greater decentralization of his kingdom. His attempted hellenization of the Jews is well known.

Under the later Seleucid kings, with rival claimants to the throne and constant civil war, Syria disintegrated. In the north the Seleucids controlled little more than the areas of Antioch and Damascus; Commagene asserted its freedom, many of the cities claimed independence, and numerous petty chiefs established little principalities. Southern Syria was partitioned by three tribal dynasties, the Ituraeans, the Jews, and the Nabataeans. The country was seized later by Tigranes of Armenia (83) until his defeat by Pompey, who ended years of anarchy by making Syria a Roman province (64–63). (See also HELLENISTIC AGE.)

**2. Roman Provincial Organization.**—Pompey in the main accepted the status quo, but he reestablished a number of cities and reduced the kingdom of Judaea; ten cities of the interior formed a league, the Decapolis. The native client kingdoms of Commagene, Ituraea, Judaea and Nabataea were henceforth subjected to Roman Syria. Parthian invasions were thrown back in 51–50 and 40–39 B.C. and Mark Antony's extensive territorial gifts to Cleopatra (Ituraea, Damascus, Coele-Syria, etc.) involved only temporary adjustments.

Under the early empire Syria, which stretched northeast to the upper Euphrates and, until A.D. 73, included eastern Cilicia, became one of the most important provinces. Its governor, a consular legate, generally commanded four legions until A.D. 70. Administrative changes followed. Rome gradually annexed the client kingdoms. Ituraea was incorporated (*i.e.*, its territories were assigned to neighbouring cities) partly in 24 B.C., partly *c.* A.D. 93. Judaea became a separate province in A.D. 6, governed by procurators (apart from the shortlived control by Agrippa I, A.D. 41–44), until the destruction of Jerusalem in 70. Then the governor was a praetorian legate in command of a legion; next, under Hadrian, he was a consular with two legions, and the province was named Syria Palaestina. Commagene was annexed temporarily from A.D. 17 to 38 and permanently by Vespasian in 72. The caravan city of Palmyra came under Roman control, possibly during Tiberius' reign. Finally, Nabataea was made the province of Arabia in 105, governed by a praetorian legate with one legion.

Syria itself was later divided by Septimius Severus into two provinces—Syria Coele in the north with two legions, and Syria Phoenice with one. By the beginning of the 5th century it was subdivided into at least five provinces. The frontiers of Syria were guarded by a fortified *limes* (*q.v.*) system, which was thoroughly reorganized by Diocletian and his successors (particularly against cavalry attacks) and which endured until the Arab conquest; much knowledge of this system of "defense in depth" has been obtained with the aid of aerial photography.

**3. Economy and Culture.**—Syria's economic prosperity depended on its natural products (*e.g.*, wine, olives, vegetables, fruits, and nuts), on its industries (*e.g.*, purple-dyeing, glassmaking at Sidon, linen and wool weaving, and metalwork), and on its control and organization of trade passing by caravan from the east to the Mediterranean through such centres as Palmyra, Damascus, Bostra, and Petra. Further, Syrian merchants spread westward throughout the Latin provinces of the Roman Empire. The population of the country must have been larger than that of today. Though some cities were founded under the empire, these were not numerous, and Syria remained essentially rural. The urban upper and middle classes might be hellenized, but the lower

classes still spoke Aramaic and other Semitic dialects in town as well as country. Roman influences were naturally weaker than Greek, though the army at first helped the spread of romanization, while Latin, not Greek, was the language of instruction in the famous law school at Berytus (Beirut) until *c.* A.D. 400.

The splendour of Syrian culture is seen in the magnificence of the cities (Antioch, ranking among the greatest cities of the empire, was the residence of the governor and later of the *comes Orientis*, who governed the diocese of the East), and in the luxury, gaiety, and versatility of the Syrians. This splendour is also evident in their schools of rhetoric, law, and medicine, in their art (the pre-eminence of Italian or Syrian elements in Syrian art is debated), in their literature and philosophy, and in the variety of their religions, both pagan and Christian.

**4. Byzantine Syria.**—During the three centuries Syria was administered from Constantinople, its cultural and economic life remained active, as names like Libanius, Ammianus Marcellinus, Procopius, and John Malalas (*qq.v.*) bear witness. Government became more bureaucratic but it was efficient. From the middle of the 5th century, by which time paganism had died out and monasticism was spreading, religious controversy took a political turn with the growth of the Monophysites (*q.v.*), in whom anti-imperial, nationalist, and secessionist sentiment found a rallying point. The repercussions of this heresy seriously weakened Syria and the Eastern Roman Empire. Nor were external dangers lacking. In the 4th century, during the campaigns of Constantius and Julian against Persia, Syria had again become a base of operations and at times endured Persian invasion; and the Huns had appeared before the end of that century. The Persian menace died down during the 5th century, but it blazed up again in the 6th, when Arabs also added to the danger. The Persian Khosrau I captured Antioch itself (540); and though he was outwitted by Belisarius and though Justinian's Persian wars ended in a "50 years' peace" (561 or 562), in 573 the Persians were back again. The invasion of Khosrau II, which began in 606, was later rolled back by the victories of Heraclius, but the peace of 628 brought no tranquillity to Syria. (H. H. Sp.; X.)

#### C. MEDIEVAL PERIOD

**1. Islamic Conquest.**—In the first half of the 7th century Syria was absorbed into the Muslim caliphate. Arab forces had appeared on the southern border even before the death of the Prophet Mohammed in 632, but the real invasion took place in 633–634, with Khalid ibn al-Walid as its most important leader. In 635 Damascus surrendered, its inhabitants being promised security for their lives, property, and churches, on payment of a poll tax. A counterattack by the emperor Heraclius was defeated at the Battle of the Yarmuk in 636; Jerusalem surrendered to the caliph Omar in 638; by 640 the conquest was virtually complete.

The new rulers divided Syria into four districts (*junds*): Damascus, Homs, Jordan, and Palestine (to which a fifth, Kinnaasin, was later added). The Arab garrisons were kept apart in camps and life went on much as before. Conversion to Islam had scarcely begun, apart from Arab tribes already settled in Syria; except for the tribe of Beni Ghassan, these all became Muslim. Christians and Jews were treated with toleration, and Nestorian and Jacobite Christians had better treatment than they had under Byzantium. The Byzantine form of administration remained but the new Muslim tax system was introduced. From 639 the governor of Syria was Mu'awiya (*q.v.*) of the Meccan house of the Omayyads. He used the country as a base for expeditions against the Byzantine Empire, for this purpose building the first Muslim navy in the Mediterranean. When civil war broke out in the Muslim Empire, as a result of the murder of Othman and the nomination of 'Ali as caliph, Syria stood firm behind Mu'awiya, who, after turning back an attack by the Iraqi Arabs at the Battle of Siffin (657), extended his authority over neighbouring provinces and was proclaimed caliph in 660, the first of the Omayyad line, which ruled the empire, with Syria as its core and Damascus its capital, for almost a century (see CALIPHATE).

**2. The Omayyads.**—The early Omayyad period was one of strength and expansion. The army, mainly Arab and largely

Syrian, extended the frontiers of Islam. It carried the war against Byzantium into Asia Minor and three times besieged Constantinople; eastward it penetrated into Khurasan, Turkistan, and northwestern India; and, spreading along the northern coast of Africa, it occupied much of Spain. This vast empire was given a regular administration which gradually acquired an Arab Muslim character. Syrians played an important part in it, and the country profited from the wealth pouring from the rich provinces to the empire's centre. The caliphs built splendid palaces and the first great monuments of Muslim religious architecture: the Dome of the Rock in Jerusalem and the Omayyad mosque in Damascus. The religious sciences of Islam began to develop, while Christian culture still flourished. Except under Omar II Christians were treated with favour; there were Christian officials at court, and the court poet of Mu'awiya, al-Akhtal, was a Christian.

Under the later Omayyads the strength of the central government declined. There were factions and feuds inside the ruling group: the Arabs of Iraq resented the domination of Syria; the non-Arab converts to Islam (*mawali*) resented the social gap between them and the Arabs; devout Muslims regarded the Omayyads as too worldly in their lives and policies; after the defeat and death of 'Ali's son Husain at the Battle of Karbala in 680, sentiment in favour of the family of 'Ali was still strong. The later Omayyads could not control these discontents. Their rule was finally overthrown and the family virtually destroyed by the new Abbasid caliphate in 750. (See also Omayyads.)

**3. The Abbasids.**—The end of the Omayyad dynasty meant a shift in power from Syria to Iraq. Syria became a dependent province of the caliphate. Its loyalty was suspect, for Omayyad sentiment lingered on, and the last pro-Omayyad revolt was not crushed until 905. The Christian population was treated with less favour; discriminatory legislation was applied to it under some caliphs, and the process of conversion to Islam went on. Closely connected with it was the gradual adoption of Arabic in place of Greek and Aramaic, although the latter survived in a few villages. (See also Abbasids.)

**4. From the 9th to the 12th Century.**—As the Abbasid caliphate disintegrated in its turn, Syria drifted out of the sphere of influence of Baghdad. In 877 it was annexed by the Tulunid dynasty of Egypt, and this began a political connection which was to last with intervals for more than six centuries. In northern Syria the Tulunids were succeeded by a local Arab dynasty, the Hamdanids of Aleppo, founded by Saif al-Daula (944-967); they engaged in war with Byzantium, in which their early successes were followed by the Greek recovery of Antioch (969). In central and southern Syria another Egyptian dynasty, the Ikshidids, established themselves (941-969); their successors, the Fatimid caliphs of Cairo, later absorbed the whole country.

In spite of political disturbances, the 10th and 11th centuries were a period of flourishing culture. Around the court of the Hamdanids lived some of the greatest Arabic writers: the poets al-Mutanabbi and Abu-al-Ala al-Ma'arri, the philosopher al-Farabi, and the anthologist Abu-al-Faraj al-Isfahani (*q.v.*). It was a period of ferment in Islamic thought, when the challenge to orthodox (Sunni) Islam from Shi'ism and its offshoots reached its height. The Fatimids were themselves Shi'is, although power moderated their beliefs. At the end of the 10th century Syria was threatened by the Karmatians, adherents of an extreme form of Shi'ism who had established a state in the Persian Gulf. The danger was beaten back, but it returned in a more insidious form as an esoteric doctrine spread by the Isma'ilis from their centre at Salamiya (Selemyia) in northern Syria. In southern Lebanon another offshoot of Shi'ism took root: the Druze religion, preached by missionaries sent from Egypt by the Fatimid caliph al-Hakim. (See Shi'ism; Isma'ilism; Druze.)

In the second half of the 11th century Syria fell into the hands of the Seljuk Turks, who had established a sultanate in Asia Minor (see Seljuks). They occupied Aleppo and then Damascus, while Jerusalem remained in the hands of the Fatimids. But after the death of the sultan Malik Shah in 1092 the Seljuk Empire fell to pieces, and between 1098 and 1124 the crusaders occupied Antioch, Jerusalem, Karak in Transjordan, and the coast.

The crusaders organized their conquests into four states owing allegiance to the king of Jerusalem (see *Crusades: Organization of the Latin States*). Their situation was precarious. The crusaders were always a minority in their states, and they never penetrated far into the interior. They could maintain their position only so long as the Muslim states surrounding were weak and divided. Zangi, the Turkish ruler of Mosul, occupied Aleppo in 1128 and recovered Edessa from the crusaders in 1144. His son Nureddin united inner Syria and annexed Egypt. After his death, his kingdom was rebuilt and strengthened by his viceroy in Egypt, Salah al-Din (Saladin; *q.v.*), who ended the Fatimid caliphate, created a strong kingdom of Egypt and Syria, and defeated the crusaders at the great Battle of Hattin (1187). He recovered all Palestine and most of the inland strongholds of the crusaders. Soon afterward, however, the Third Crusade recaptured part of the coast, where European rule lingered for another century.

**5. The Ayyubids and Mamelukes.**—After Saladin's death his kingdom was split up among members of his family, the Ayyubids, who established principalities in Aleppo, Hamah (Hama), Homs, Damascus, Baalbek, and Transjordan and ruled them until 1260. The period of Nureddin, Saladin, and their successors was of great importance. Thanks largely to the establishment of Italian trading centres on the coast, and better security, economic life recovered and Syria reached a level of prosperity such as it had not enjoyed for centuries. The Ayyubid rulers stimulated culture and architecture. Following the Seljuks, they created a new land system based on the grant of rights over land in return for military service. They were champions of Islamic orthodoxy against the sects which had gained ground in the previous era. They supported orthodox theology and law and built colleges of a new type, the madrasas, as centres of orthodox learning. Their efforts to stamp out heterodoxy were not completely successful. The Isma'ilis kept their strongholds in the Jabal Ansariyah, and their secret organization, the Assassins, had some political importance (see Assassins). The Druze religion spread further.

Although strong internally the state was still in danger from the Bedouin tribes of the desert and from the Mongols, who invaded Syria for the first time in 1260 and sacked Aleppo. They were driven back not by the local rulers but by a new Egyptian military group, the Mamelukes (see Mameluke), a self-perpetuating élite of slaves and freedmen, mainly of Turkish and Caucasian origin, who had replaced the Ayyubids as rulers of Egypt in 1250. In 1260 they defeated the Mongols at the Battle of Ayn Jalut in Palestine; the victorious Mameluke general, Baybars, made himself sultan of a reunited kingdom of Syria and Egypt which he ruled until his death in 1277. This state continued to exist for over two centuries. In 1291 it won back Acre and other coastal towns from the crusaders, and a few years later it took the last crusading stronghold, the island of Ruad (Arwad). The Mamelukes reorganized the Ayyubid principalities as six provinces, of which Damascus was the largest and most important. Political power was in the hands of the Mameluke élite, who held land in virtual ownership in return for military service in the cavalry. But there was a local element in the government, the civil servants being drawn mainly from Syrian Arab families with their tradition of religious learning. Local rulers such as the Buhturids of Lebanon were recognized and absorbed into the "feudal" system.

Like the Ayyubids the Mamelukes were strictly orthodox in religion. Religious culture flourished and produced a number of great scholars such as the Hanbali jurist Ibn Taimiya. Alike for religious and political reasons the Mamelukes dealt severely with the religious minorities living in the coastal mountain ranges: Druze, Maronite Christians, Isma'ilis, and Alawites (or Nusairis; adherents of another creed derived from extreme Shi'ism and living in the Jabal Ansariyah). In the early Mameluke period Syria remained prosperous; the rulers constructed public works, and Venetian merchants carried on their coastal trade. But in 1401 came a blow to economic life: a new Mongol invader, Timur (Tamerlane), sacked Aleppo and Damascus. His empire did not long survive his death in 1405, but the damage had been done. The cities had been burnt, a large part of their population killed, and many craftsmen taken away to central Asia.

## D. OTTOMAN PERIOD

**1. Ottoman Government, 16th-17th Centuries.**—Through-out the 15th century Mameluke Syria continued to decline, while a new power was growing to the north, that of the Ottoman Turkish sultanate in Asia Minor. Having occupied Constantinople and the Balkans it began to look southward. In 1516 Sultan Selim I defeated the Mamelukes at the Battle of Marj Dabiq and occupied the whole of Syria that year and Egypt the next. While Egypt later recovered some autonomy under the Mamelukes, Syria remained for 400 years an integral part of the Ottoman Empire. It was divided into provinces each under a governor: Damascus, Aleppo, and later Tripoli and Saida (Sidon, of which the administrative centre was later moved to Acre). Damascus, the largest, had special importance as the place from which the pilgrimage to Mecca was organized every year. The governor of Damascus led the pilgrimage when possible, and most of the revenues of the province were earmarked for its expenses.

The tax system continued in principle to be that of Muslim law—land tax, poll tax on Christians and Jews, and customs duties. But the Ottomans like their predecessors gave the right to collect and keep the land tax in return for military service and thus created a virtual landowning class. Later this system was allowed to decay, and tax collection was turned over to tax farmers (*multazims*), who themselves became in course of time a landowning class. Another official hierarchy, the religious hierarchy of judges, jurisconsults, and preachers, served as intermediary between government and subjects.

Within this framework of law, order, and taxation, the local communities were left to regulate their own lives. In the desert, the Bedouin tribes were controlled to some extent by gifts, the encouragement of factions, and occasional military expeditions, but otherwise were not interfered with. In the mountains, the Maronites and other Christians, Druze, and Shi'i Muslims of Lebanon, the Alawites, and Isma'ilis of Jabal Ansariyah, were watched by the Turkish governors of Tripoli, Sidon, and Damascus but were not interfered with so long as they paid their taxes. The Druze princes of Lebanon, first of the Ma'anid and then of the Shihabid family, were recognized as governors and chief tax collectors. In the Jabal Druze south of Damascus there grew up a community of Druze farmers under no control and paying no taxes. The authority of the Christian patriarchs over their communities was recognized, and in the corps of '*ulama*' (*q.v.*) most positions except the highest were held by members of local families with a tradition of religious learning, who continued to be, as under the Mamelukes, spokesmen and leaders of the Muslim citizens.

The early Ottoman governors paid much attention to agriculture, and their fiscal system was designed to encourage it. In parts at least of Syria it flourished during the 16th and 17th centuries, and, apart from cereals for local consumption, cotton and silk were produced for export. Aleppo and Damascus not only were important centres of handicrafts but also served as market towns for the desert and countryside and as stages on the desert routes to the Persian Gulf and Persia. Aleppo and Sidon were also important centres of trade with Europe; French and English had largely replaced Italian merchants, and there grew up also a class of Syrian Christian and Jewish merchants who developed contacts with Egypt, Italy, and France. Throughout the 17th and 18th centuries the position of the Christians indeed improved. Catholic missions, protected by France, enlarged the Catholic communities of both Latin and Eastern rites, founded schools, and spread the knowledge of European languages. The Oriental colleges at Rome produced an educated priesthood, and the Christian communities in Aleppo and Lebanon brought forth scholars such as the famous Joseph Assemani, Vatican librarian, and Arabic writers such as Germanos Farhat, Maronite archbishop of Aleppo. The traditional Muslim Arab culture could still produce a theologian of some originality in 'Abd al-Ghani al-Nabulsi and a systematic jurist in Ibrahim al-Halabi.

**2. Decline of Ottoman Authority.**—In spite of a widespread revolt in the early 17th century, Ottoman rule was in general stable and effective until the end of that century. After that it declined rapidly, in Syria as elsewhere. Control by the central government

weakened; the standard of administration sank; the janizaries lost their discipline and became a menace to order. The result was a shrinkage of agricultural production as the villages suffered from the depredations of soldiery and tax collectors and from Bedouin incursions. This was a period of activity in the Syrian Desert, and tribes of the 'Anaza federation, moving northwest from Arabia, extended their control far into the settled land. In the towns also there was a decline. The desert routes were unsafe, and the European merchant colonies were shrinking. But there was still a vigorous commercial life, the standard of craftsmanship was high, and the great tradition of Islamic architecture continued.

Ottoman authority did reassert itself to some extent, but in a new form. For most of the 18th century Damascus was ruled by governors belonging to the 'Azm family, loyal to the sultan but with more independence than earlier sultans would have allowed. They controlled the janizaries, kept back the Bedouin, maintained security, and sometimes extended their authority to other provinces. In the province of Sidon power was held on similar terms by a ruthless and able Bosnian governor, Ahmad al-Jazzar (1775-1804), and his group of Mamelukes. Such rulers raised their own armies, but this involved further taxation and depressed further the condition of the peasants. Agriculture flourished only in the hilly districts which were virtually beyond Ottoman control, free from Bedouin attacks, and ruled by strong local rulers such as Dahir al-'Umar (1750-75), who protected agriculture and made Acre a prosperous centre of trade. In Lebanon too the production of silk flourished under the protection of the Shihabs and other great families.

**3. Early 19th Century.**—At the beginning of the 19th century, the population of Syria was perhaps 2,000,000. There were some islands of prosperity: Aleppo and Damascus (each with roughly 100,000 inhabitants), Mt. Lebanon, and certain other secluded districts. In general, however, the country was in decay, the small towns subsisting on local trade, the villagers receding in face of the Bedouin. The Ottoman hold on the country was at its weakest. At Acre, it is true, Jazzar maintained his strong rule and was able, with the help of a British fleet and the Turkish army, to hold Bonaparte back when he invaded Palestine in 1799. But in Damascus and Aleppo the governors were scarcely able to control the population of city or countryside. The prince of Lebanon, Bashir II (1788-1840), who had been installed by Jazzar and remained quiet while Jazzar was alive, gradually extended his control over districts beyond Lebanon. In 1810 the Wahhabis from central Arabia threatened Damascus.

**4. Egyptian Domination.**—In 1831 the ruler of Egypt, Mohammed Ali, sent his son Ibrahim Pasha (*q.v.*) at the head of his modern army into Palestine. Helped by Bashir and other local leaders, Ibrahim conquered the country and advanced into Asia Minor. He ruled Syria for almost ten years. The whole country was controlled from Damascus. There and in the provincial centres the governors were Egyptians, but they were assisted by councils representing the population. In political matters Ibrahim relied largely on Bashir, in financial concerns on a Syrian Christian adviser. New taxes were introduced and strictly collected, agriculture was encouraged, and the Bedouin were pushed back. After an abortive attempt to introduce trade monopolies, Ibrahim encouraged European traders by maintaining better security and creating special commercial courts. It was in this period that Beirut began to replace Sidon as an international port. The Christian and Jewish populations were treated with consideration.

After a time Ibrahim's rule became unpopular because his taxes were heavy and he disarmed and conscripted the population. The European powers (except France) also objected to Egyptian rule in Syria because it was a threat to the Ottoman Empire, the weakness or disintegration of which might cause a European crisis. In 1839 war broke out between Mohammed Ali and his suzerain, the sultan. Ibrahim defeated the Turkish army, but in 1840 the European powers intervened. After an ultimatum, a British, Turkish, and Austrian force landed on the Syrian coast; there was a local insurrection encouraged from outside, and the Egyptians were forced to withdraw from Syria, which reverted to the sultan's government.

**5. Ottoman Rule Restored.**—The next 20 years were a period of mounting crisis. Bashir II was deposed by the Ottomans because of his support of the Egyptians; his successor could not control the population and was soon deposed. Shihabid rule came to an end, and Lebanon became the scene of a struggle for power between Druzes and Maronites, with undertones of social conflict. In the rest of Syria, an attempt was made to apply the new Ottoman administrative system. The new system of taxation and conscription caused unrest. This situation was increased by the growth of European influence. The Muslim majority became aware of the weakness of the Islamic community, and the connection of France with the Catholics and of Russia with the Orthodox both encouraged the minorities to hope for a more favourable position, and focused on them the hostility of their Muslim compatriots. There was also economic unrest. From the 1820s European goods flooded the market and replaced the products of local craftsmen. This diminished the prosperity of the artisan class, largely Muslim, but increased that of the merchants, mainly Christians and Jews, who handled imports.

The tension generated in these ways burst out in 1860, when a civil war of Druzes and Maronites in Lebanon touched off a massacre of Christians by the Muslim mob in Damascus. The Ottoman government sent a special commissioner to punish the guilty and suppress disorder. France sent an expeditionary force, and a European commission discussed the future of the country and decided that Lebanon (the mountain itself but not the coastal towns) should be an autonomous district (*mutasarrifiyah*), but no change should be made in the rest of Syria.

From then until the collapse of the empire Syria continued to be governed as a group of Ottoman provinces. From 1888 there were three: Damascus, Aleppo, and Beirut. The new administrative and legal system was more carefully applied, and a new type of educated official gradually raised its standards. The introduction of railways and telegraphs made possible a stricter control. A French-built railway linked Beirut and Damascus, with a later extension running north to Aleppo, and in 1908 the Hejaz railway was opened to take pilgrims from Damascus to Medina. Railways and better security encouraged agriculture. Transjordan and Al Jazirah, the district between the Upper Euphrates and Tigris, ceased to be wholly nomadic. In other parts, however, the growth of population outran the increase of production, and there began a large-scale emigration to North and South America. The trade of Beirut increased steadily: its modern harbour was built by a French company, and by 1914 its population had grown to about 150,000. Aleppo (pop. about 200,000) and Damascus (pop. about 250,000) both had a flourishing trade, but the crafts declined, and the desert routes had suffered from the opening of the Suez Canal.

In Beirut and other cities there was a considerable change in social life: the upper and middle classes adopted the clothes and social customs of Western Europe. Schools on the Western model increased. The mission schools expanded: in 1866 the American Protestant Mission opened in Beirut the Syrian Protestant College (later the American University of Beirut), and in 1881 the French Jesuits opened the University of St. Joseph in the same town. The Ottoman government also opened schools, and young men of the great Arab families of the towns began to attend the higher schools in Constantinople and from them enter the civil or military service.

Under Sultan Abdul-Hamid II (1876–1909) the Muslim Arabs of Syria were reasonably content. His emphasis on Islamic solidarity frightened the Christians, but the Muslims on the whole still regarded the Ottoman Empire as the political embodiment of Islam. Syrian Arabs played a leading part at the sultan's court.

After the Young Turk revolution of 1908 relations between Arabs and Turks grew worse. Power fell into the hands of a Turkish military group whose policy stimulated the growth of opposition. Arab nationalist feeling became more conscious, and political parties, both open and secret, were organized by Syrians in Cairo, Constantinople, and Paris as well as in Syria itself. Their explicit demand was for an improved status within the empire and some local autonomy, but there was a growing feeling in favour of independence and the establishment of a Syrian or Arab state.

This was the aim of the secret Fatat Party founded in 1911. Many Christians, particularly Maronites and other Catholics, wanted an independent Lebanon with extended frontiers and under French protection. Among the nationalists were some who looked to England and France as allies in the struggle for independence, but others were conscious of danger from the outside. Foreign spheres of influence were growing: France had paramount influence on the Syrian coast and in Lebanon, while in Palestine all the powers competed for influence, and from the 1880s there had begun Jewish immigration from Russia and Eastern Europe with the aim of creating for the Jews a national home under international guarantee.

**6. World War I and After.**—When the Ottoman Empire entered World War I in 1914, Syria became a military base. In 1915 an Ottoman army under German command attacked the British position on the Suez Canal, and then from 1916 a British and Imperial force based on Egypt, with a French contingent, undertook the invasion of Palestine. By the end of 1917 Gen. Sir Edmund (later Field Marshal Viscount) Allenby had occupied Jerusalem and by November 1918 the rest of Syria. Most Christians and Jews welcomed the occupation; among the Muslims a large proportion had remained loyal to the empire, as being all that was left of the political independence of Islam, but the nationalist societies had made common cause with the ruler of the Hejaz, Sharif Husain, forming an alliance with Britain against their Turkish suzerain. An Arab army under the command of Husain's son Faisal, was formed in the Hejaz, with Syrian and other Arab officers and British help (see LAWRENCE, THOMAS EDWARD). It took part under Allenby's general command in the Syrian campaign, operating on the east flank in Transjordan and helping to capture Damascus.

When the war ended, Allenby installed an Arab military administration under Faisal in Damascus and the interior. The French took over the coast with Beirut as their centre, and the British took over Palestine. There followed four unsettled years while the fate of Syria was being decided. During the war the British government had made promises, to Husain and other Arab leaders, that the Arabs would be independent in those countries which they helped to liberate, subject to certain reservations of which the precise extent has never been clear. Then, in November 1918, Britain and France declared their intention of establishing in Syria and Iraq "national governments drawing their authority from the initiative and free choice of the native populations."

By the Sykes-Picot Agreement of 1916 (see SYKES, SIR MARK), France was to be free to establish what administration it pleased in Lebanon and on the coast, and to provide advice and assistance to whatever regime existed in the interior; Britain was to have similar rights in Transjordan and Iraq. Palestine was to be under international control, but France later agreed that it should be in the British sphere, while Britain had already, by the Balfour Declaration of November 1917, pledged conditional support for the establishment of a Jewish national home. It proved impossible to reconcile the various claims and pledges. In March 1920 a Syrian Congress meeting in Damascus elected Faisal king of a united Syria including Palestine; but in April the Allied Conference of San Remo decided that both should be placed under the new mandate system, and that France should have the mandate for Syria.

#### E. MANDATE AND INDEPENDENCE

**1. The French Mandate.**—In June 1920 a French ultimatum demanding Syrian recognition of the mandate was followed by a French occupation and the expulsion in July of Faisal. In July 1922 the League of Nations approved the texts of the British Mandate for Palestine and Transjordan and of the French Mandate for Syria and Lebanon. Lebanon had already, in August 1920, been declared a separate state, with the addition of Beirut, Tripoli, and certain other districts, to the prewar autonomous province. Politically "Syria" henceforth acquired a narrower meaning; it referred to what was left of geographical Syria once Transjordan, Lebanon, and Palestine had been detached from it.

The mandate placed on France the responsibility of creating

and controlling an administration, of developing the resources of the country, and of preparing it for self-government. A number of local governments were set up: one for the Jabal Ansariyah, where the majority belonged to the 'Alawi sect, one for the Jabal Druze where most of the inhabitants were Druzes, and one for the rest of Syria with its capital at Damascus. Inside this last, a special status was given to the district of Alexandretta (Iskenderun), with its mixed population, Arab, Turkish, and Armenian, and also (in fact although not officially) to Al Jazirah, where Kurds, Arabs and Christians, nomads and peasants, lived together. All three governments had indigenous administrations, with French advisers, and there was a French supervisory administration under the high commissioner for Syria and Lebanon at Beirut.

The French mandatory administration carried out much constructive work. Roads were built; town planning was carried out, and urban amenities were improved; land tenure was reformed in some districts; and agriculture was encouraged, particularly in the fertile Al Jazirah. Some encouragement was given to industry. Foreign mission schools were protected and helped, but a system of state schools also was constructed, and the University of Damascus was established with its teaching being mainly in Arabic. Ancient sites were excavated and museums opened.

It was more difficult to prepare Syria for self-government because of the difference between French and Syrian conceptions of what was implied. Most French officials and statesmen thought in terms of a long period of control; the French army wanted strategic control of both Syria and Lebanon; French politicians hesitated to make concessions to Syria which might arouse expectations in North Africa. Further, they did not wish to hand over power to the Muslim majority in a way which might persuade their Christian protégés and clerical groups in France that they were giving up France's traditional policy of protecting the Christians of the Levant. In Syria, many members of the minorities and a smaller proportion of the majority wanted the French to remain as a help in constructing a modern society and government. The greater part of the urban population, however, and in particular the educated élite, wanted Syria to be independent and to include Lebanon, Palestine, and Transjordan if possible, and certainly the Druze and 'Alawi districts.

The first crisis in Franco-Syrian relations came in 1925, when a revolt in Jabal Druze, due to local grievances, led to an alliance between the Druze rebels under Sultan al-Atrash and the nationalists of Damascus, newly organized in the People's Party. For a time the rebels controlled much of the countryside. They penetrated into Lebanon and the orchards of Damascus. In October 1925 bands entered the city of Damascus itself, and this led to a two-day bombardment by the French. The revolt did not subside completely until 1927, but even before the end of 1925 the French had started a policy of conciliation. In 1928 elections were held for a Constituent Assembly. The nationalists won the election and took office in a new government. The assembly drafted a constitution, but their draft was not wholly acceptable to the high commissioner because it spoke of the unity of geographical Syria and did not explicitly safeguard the French position of control.

*Treaty of 1936.*—In May 1930 the high commissioner dissolved the assembly and enacted the constitution with certain changes. There followed unsuccessful negotiations for a Franco-Syrian treaty; but in 1936 the advent of the Popular Front government in France, the growing tension in the Mediterranean, and the grant by Britain of independence to Iraq (1932) and to Egypt changed the situation. Negotiations took place with the nationalists, now organized in the "National Bloc." A treaty was signed in September 1936. It provided for Syrian independence, Franco-Syrian consultation on foreign policy, French priority in advice and assistance, and the retention by France of two military bases. The Druze and 'Alawi districts were to be incorporated in Syria, but not Lebanon, with which France signed a similar treaty in November. A Parliament was elected; the leader of the Bloc, Hashim al-Atasi (*q.v.*) was chosen as president of the republic; and a nationalist government took office.

The Syrian government ratified the treaty before the end of

1936, but France never did so, partly because of the pressure brought by those, in France and Syria, who were opposed to it, partly because a series of weak governments hesitated to surrender French control of a vital strategic territory with war obviously drawing near. Internally, too, the new government was faced with difficulties. There was opposition in the Druze, 'Alawi, and Al-Jazirah districts, encouraged by some French officials. The Palestinian Arab revolt, beginning in 1936, aroused strong sympathy in Syria, and to the north Turkey put forward claims to Alexandretta, where Turks were the largest element in the mixed population. In spite of opposition from Arabs and Armenians, and of its own obligations under the mandate, France found it advisable, for strategic reasons, to yield to the Turkish demands. In 1937 the district (later given the Turkish name of Hatay) was granted an autonomous status; in 1939 it was incorporated in Turkey.

By the end of 1938 it was clear that the French government had no intention of ratifying the treaty. In July 1939 the president and government resigned, and the constitution was suspended.

**2. World War II and Independence.**—The outbreak of World War II ended political activity for the time. In June 1940, after the Franco-German armistice, the French high commissioner and commander in chief announced that they would cease hostilities against Germany and Italy and recognize the Vichy government. During the next year an Italian and then a German armistice commission were active. Political uncertainty and the growing scarcity of goods and rising prices caused unrest, which was led by one of the prominent nationalists, Shukri al-Kuwatli (*q.v.*). In May 1941 the Vichy government allowed German aircraft to land and refuel en route to Iraq, where hostilities had broken out between the British and a government favourable to Germany; and in June, British, Commonwealth, and Free French forces invaded Syria and Lebanon. French troops in Syria resisted for a month, but Damascus was occupied on June 21 and hostilities ceased at midnight on July 11–12.

From then until 1946 Syria was jointly occupied by British and French forces. General military command was British, territorial command French, and a Free French Délégué-General (at first, Gen. Georges Catroux) had administrative authority. At the moment of invasion, the Free French had proclaimed Syrian and Lebanese independence, and this was underwritten by the British government which, in the agreement reached between Gen. Charles de Gaulle and Capt. Oliver Lyttelton (later Lord Chandos), British minister of state in the Middle East, in August 1941, recognized French predominance in Syria and Lebanon provided France carried out its promise of independence.

Differences about policy soon arose. The Free French did not wish to grant independence until France was restored, and even then only in return for a treaty similar to that of 1936. The Syrian and Lebanese nationalists were unwilling to sign treaties, and wished to obtain independence before the British troops left. In the interests of its Arab policy, Britain used its position of strength to persuade the Free French to carry out their undertaking. Elections held in 1943 resulted in a nationalist victory, and Shukri al-Kuwatli became president of the republic.

There followed two years of disagreement about the transfer of authority from the French administration to the Syrian and Lebanese governments. The first crisis occurred in 1943 when an amendment of the Lebanese constitution in the direction of complete independence led to the arrest of the Lebanese government, and their release after a British ultimatum; and the second in 1945, when the French refusal to transfer control of the local armed forces led to disorders, culminating in a French bombardment of Damascus and British intervention. After long negotiations and discussion in the UN Security Council, agreement was reached on simultaneous British and French withdrawal from Syria and Lebanon. Withdrawal from Syria was completed by April 1946. Syria had already become a founder member of the United Nations and of the Arab League.

**3. Post-1945 Developments.**—Since World War II the Syrian economy, despite uncertainty caused by the transition from *laissez-faire* capitalism to socialistic planning, has been remarkably resilient (see *The Economy*, below).

Political development has been less steady than economic. The National Bloc, which had led the struggle for independence, held office until 1949, but gradually lost its popularity because of administrative corruption, the high cost of living, and the Arab failure in the Palestine War of 1948-49. In 1949 the army intervened: a *coup d'état* by Husni al-Za'im in March was followed by a second in August, led by Sami al-Hinnawi with the support of another nationalist group, the People's Party. Hashim al-Atasi became president, and negotiations took place for a union with Iraq. These were cut short by a third military coup, that of Adib al-Shishakli in December. For two years Shishakli ruled in combination with the politicians, but from 1951 to 1954 Shishakli ruled by himself. In foreign affairs he followed a policy more favourable to Egypt than to Iraq. He was dislodged by a further army revolt in February 1954, and constitutional rule was restored. Al-Atasi was restored to office, to be succeeded in 1955 by al-Kuwatli.

Elections in 1954 resulted in a Parliament of various groups, including the Baath Party, which combined radical Arab nationalism with a policy of social reform, and made a special appeal to the new educated classes. For the next few years there was a struggle for power. The Baath, allied with an army group led by 'Abd al-Hamid Serraj, outwitted the others. Their policy was for union with Egypt, and at the time of the Suez crisis (1956) they were responsible for blowing up the oil pipeline in Syria.

In 1957, however, they themselves seemed likely to be outbid by a combination of politicians and officers standing further to the left. Syrian policy and opinion seemed to be moving toward the U.S.S.R., with which an arms agreement (1956) and economic agreement (1957) were made. To check this development, the Baath persuaded Egypt to unite with Syria in the United Arab Republic (February 1958). The republic was to have an elected president, a central government including Syrian and Egyptian members, and regional governments. Later, a National Assembly was chosen, one-third of the members of which were Syrians.

*The Union with Egypt.*—At first the new state was ruled by a combination of the Egyptian military group with the Baath, held together by a common neutralist foreign policy and an empirical policy of social reform. But soon the balance of power tilted in favour of the central as against the regional governments, and of Egyptians as against Syrians. In October 1959 the president, Gamal Abd-al-Nasser, appointed his closest associate, Field Marshal 'Abd al-Hakim Amer, as virtual governor of Syria, and in December the Baathist members of the ministry resigned. 'Abd al-Hamid Serraj, however, remained as minister of the interior, and in September 1960 was appointed head of the Syrian regional government. Dislike of Egyptian administrative control and a succession of bad harvests caused discontent. This was increased in 1961 by U.A.R. measures of economic control and nationalization and in September 1961 Syrian officers in the army carried out a *coup d'état*. Syria withdrew from the union, and as the "Syrian Arab Republic" reentered the Arab League and the UN.

*Syrian Arab Republic.*—A period of instability followed the secession, with the older nationalist groups, the Baath, and pro-Egyptian elements struggling for power. At first there was a constitutional government dominated by bourgeois nationalists, with Nazim al-Kudsi as president. A further *coup d'état* in March 1962 led to a suspension of constitutional rule, and an uneasy balance between bourgeois and radical elements. In 1963 another *coup d'état* installed a largely Baathist government with civilian and military elements; during 1963-64 power fell increasingly to the military. Lieut. Gen. Amin al-Hafez became chairman of the Presidential Council, premier and *de facto* president.

In 1963 the Baathist government held discussions on union with Egypt and Iraq (which also had a Baathist government at the time); but the agreement reached in April 1963 was abortive, and later Hafez's government became more hostile to Egypt, although common fear of Israeli expansion drew them together and Syria took part in the regular Arab League's "summit" conferences to concert anti-Israeli action. Internally the government followed a policy of economic control. It attempted to obtain help from the Federal Republic of Germany and France for constructing the Euphrates Dam; the Soviets were eventually awarded the con-

tract. In 1964 it started to nationalize industry, commerce, and oil distribution; this caused some unrest in the mid-1960s. A provisional constitution under which Syria would become a "Socialist People's Democratic Republic" was promulgated on April 25, 1964; in August 1965 a National Revolutionary Council was created to draft a permanent constitution.

In January 1966 a new 26-man cabinet headed by Salah al-Bitar, a moderate, was set up to replace that of the Baathist extremists, led by Yussef Zayen, which had resigned the preceding month. In late February, however, left-wing elements of the Syrian Army and the Baath Party seized power in a bloody coup, denouncing both Hafez and Bitar as reactionaries. The regime was expected to move to the left in policy matters. (A. H. H.)

Syrian sabotage raids into Israel assumed serious proportions in 1967 and culminated in heavy fighting on the border on April 7. Continuance of the raids led to reprisal threats from Israel, and Egypt, in pursuance of its mutual security pact with Syria, moved troops into the Sinai peninsula and requested the withdrawal of UN troops from Egyptian territory (May 17). When war broke out between Israel and Egypt in the Sinai peninsula on June 5, Syria was fully committed and fighting started almost immediately on the Syrian-Israeli border. On June 8 Syria accepted the UN cease-fire call. See also LEBANON: *History*; EGYPT: *History*; UNITED ARAB REPUBLIC; ARAB LEAGUE. (X.)

### III. POPULATION

The 1960 census gave a total population of 4,565,121. Populations of the major towns were: Damascus (capital, 529,963); Aleppo (425,467); Homs (137,217); Hamah (Hama; 97,390); Latakia (Al Laziqiyah; 67,604); and Dayr az Zawr (42,036). Palestinian refugees numbered more than 150,000 and lived on the outskirts of Damascus in camps maintained by the United Nations Relief and Welfare Agency. The nomadic Bedouin population, which has declined steadily since World War II, was estimated to be less than 200,000. The greatest population density is in the Hawran, Jabal Druze, and Hamah regions.

Most Syrians are of Semitic stock (primarily Arab) and speak Arabic, the official language. Kurds and Armenians are the principal minorities. The former live in Turkish border areas and in Damascus. The Armenian communities, both Orthodox and Catholic, number about 150,000 and live mainly in Damascus and Aleppo. The Assyrians, estimated at 20,000, often speaking the Syriac language (*q.v.*), live in villages along the Nahr al Khabur in the northeast, and on the western slopes of the Anti-Lebanon Mountains. Christians of various denominations but mainly Orthodox comprise less than 8% of the population; they have long been involved in commerce and are largely an urban middle-class community. There are more than 5,000 Jews.

Religious divisions are numerous and politically important, although less so than earlier in the 20th century. The main Muslim sects are orthodox Sunnis (the majority), Shi'a, Alawite (Alaouite or Nusairi), Isma'ili, and Druze. The Druze (160,000) and the Alawites (500,000) exert a disproportionate amount of influence. See also ARAB; KURDS; DRUZE; BEDOUIN.

### IV. ADMINISTRATION AND SOCIAL CONDITIONS

**1. Government.**—After the Socialist Baath Party seized power in 1963 (see *History* above) a coalition of army officers and civilians (styled the National Revolutionary Council) ruled the country. Executive power was vested in the Presidential Council and the Cabinet (which has been frequently changed); the former has delegated the tasks of administration to growing cadres of bureaucratic technicians headed by cabinet ministers. Before Aug. 23, 1965, the Presidential Council, whose membership except for that of its chairman (Pres. Amin al-Hafez) was secret, made policy decisions and administrative appointments. On Aug. 23 the Presidential Council appointed a National Council of 95 members to serve as a constitutional assembly with the responsibility of assuming the duties of the Presidential Council, preparing a constitution, and submitting it for a general referendum. In September the National Council elected a new 5-man Presidency Council to exercise the authority of head of state.

## Administrative Subdivisions of Syria

Muhafasat (Provinces)	Area* (sq.mi.)	Population (1960 census)	Density (per sq.mi.)
Dar'a (Der'a)	1,622	167,515	103.3
Dayr az Zawr (Deir ez Zor)	12,764	221,320	17.3
Dimashq (Damascus)	7,341	346,760	47.1
Dimashq (Damascus), Municipality of	198	656,096	3,313.6
Halab (Aleppo)	6,232	957,399	153.6
Hamah	3,213	324,627	109.8
Hasakah, Al (El Haseke)	9,024	352,893	39.1
Homs	16,290	401,243	24.6
Idlib (Idleb)	2,424	332,778	137.3
Laziqiyah, Al (Latakia)	1,753	526,551	300.4
Raqqah, Ar (Rakka)	8,494	178,417	21.0
Suwayda', As (Es Suweida)	2,143	99,519	46.3
Total	71,498	4,565,118	63.8

Muhafasat are named after their capital cities.

\*1 sq.mi. = 2.59 sq.km.

Administratively the country is divided into 11 *muhafasat* (provinces) (see Table). These are subdivided into 37 *mantiqat* (districts) which are further subdivided into 99 *nahiyat* (subdistricts). The smallest unit is the village of which there are more than 8,000. The Ministry of the Interior appoints the *muhafiz* (governor) and other district officers.

**Political Organizations.**—Political parties, although prohibited, except for the Baath, were not dormant in the 1960s. A general amnesty for political prisoners was granted in August 1964.

The Communists remained a *petit bourgeois* group drawn mainly from the professional classes and the religious minorities, with a smattering of support from the peasantry. There were signs of Communist influence in the small new industrial proletariat. Conservative forces in Syria were represented by the People's Sha'ab Party and the National (*Watani*) Party, twin heirs of the broadly based National Bloc which until World War II led the struggle against the French Mandate administration. The Muslim Brotherhood (*Ikwan al muslimine*), opposed to both Nasserism and Communism, enjoyed a following among the traditionally fervent masses in Damascus, although in Syria it was never a paramilitary, terrorist organization as in Egypt. The Ba'ath al-Arabi (Baath or Arab Renaissance) Party which controls the government was founded in 1941 by Michael Aflaq and Salah al-Din Bitar to preach related doctrines of Arab unity and socialism (see *History* above). The Socialist Party, founded in 1952 by Akram al-Hawrani, was essentially a peasant organization based initially on the rural Hamah district in central Syria.

**2. Justice.**—Judicial power is exercised by the People's Court, Courts of the Peace, and other courts and special tribunals. The People's Court at Damascus (established 1962) holds public trials of persons accused of crimes against the state. Religious courts, once a major source of justice in Muslim Syria, are now superseded by civil courts; they still, however, handle some questions involving personal status such as marriage and divorce.

**3. Taxation, Living Conditions, and Welfare Services.**—The guideline for tax reform under the Baath regime indicated that direct taxation would increase at the expense of indirect. The cost of living as measured by the Ministry of Planning's analysis of retail prices in five cities has slowly risen since 1955 at the average annual rate of less than 2%. The average annual increase in per capita income in the 1960s, after adjustments for inflated national income estimates, was less than 2%. The five-year plan (1960-65) sought a rate of 5%. Government housing programs were mainly restricted to Damascus.

The Labour Code of 1946 regulated conditions of work in industry, but did not apply to farm workers. Efforts to legislate agrarian reform met with little success because of opposition of the landowners, and it was not until September 1958 that measures, including regulations concerning landlord-tenant relationships, succeeded (see *Land Reform* below). In August 1959 a labour and social insurance code unifying the labour laws of Egypt and Syria came into force. It advocated an 8-hour day and a 48-hour week, plus health and accident insurance, and applied to both agriculture and industry. By decrees of March 1964 farm labourers were to receive 40% of the crop (10% more than the traditional share), depending on the services supplied; they could also negotiate an agreement (usually 35%) with consent of both parties.

The average wage for unskilled farm labourers ranged from \$45 a day in the more populated areas to \$48 in Al Jazirah.

The social structure has undergone profound change since independence. Progress in health and education had by the 1960s been extended from towns to rural areas. In regions no longer dominated by landlords there was a marked change in the attitude of the peasants whose subservience to landlord rule began to give way to independent thought and action. Increased freedom encouraged seasonal migration, both rural and urban.

**Health.**—By the mid-1960s malaria was almost eliminated. Diseases such as tuberculosis, trachoma, and dysentery were on the decline because of improved water facilities and rural medical treatment through clinics built by the villagers and staffed by government employees. Shells of incomplete hospitals, however, are testimony to manpower deficiencies.

**4. Education.**—Primary education is free and compulsory. By the mid-1960s there were more than 3,800 primary schools with 600,000 pupils and 16,000 teachers. Secondary schools totaled about 600 with 120,000 students and 4,500 teachers. There were also 45 vocational schools and 9 teachers' training colleges. The University of Damascus, founded in 1923, was in the mid-1960s considerably overcrowded with an enrollment of more than 30,000 full- and part-time students. Aleppo University (1960) with faculties of arts, science, engineering, law, Islamic law, education, dentistry, medicine, and business administration, had more than 6,000 students. In Damascus are the Arab Academy (1919), a higher polytechnic institute (1961), and institutes of music, agriculture, and social service.

**5. Defense.**—Syria is associated with the tenuous joint defense measures against Israel taken at the Arab League's summit conferences; in the 1960s its army was mainly occupied with guarding the border with Israel. The so-called Palestine Liberation Army received training facilities on Syrian soil, but was not responsible to the Damascus government.

The Syrian Army, formed in 1946 after the departure of foreign troops, drew its first recruits from officers and men who had served in the *Troupes spéciales du Levant*, a force raised locally by the French under the mandate. But the Palestinian War of 1948 against Israel found it woefully undermanned and under-equipped. It expanded, however, during the various military regimes established after 1949, notably that of Adib ash-Shishakli who sent teams of officers to study abroad. Impatient with Western restrictions on arms supplies to the Middle East, Syria concluded an arms deal with the Czechs (in 1954) which set the pattern for subsequent contracts. The Syrian armed forces totaled about 70,000 officers and men and included the gendarmerie and civil police (about 6,500) and the Bedouin Control Force (about 1,000). Syria has several military colleges—namely the school for officer cadets at Homs. Military service was obligatory under the 1964 provisional constitution.

## V. THE ECONOMY

The bulk of the population is engaged in agriculture which in the mid-1960s provided about one-third of the national income. Syria is not a major producer of crude oil. Following independence, Syrian economic development experienced two distinct phases influenced by political factors at home in the Arab world and from the cold war. The first phase, the decade following World War II, was the period of *laissez-faire* capitalism which saw the development of the dry farming areas of Al Jazirah and the irrigation of lands adjoining the Euphrates and Khabur rivers. Reinvested war profits found a high return in grain and cotton farming. Crop production increased and the average per capita income growth was higher than for any other Arab country during the same period. However, by 1954 the growing power of the Socialists and their attempts to enact land reform plus the inclusion of a Communist in the cabinet caused the rate of investment in agriculture to decline. The economy lost its sustaining force. The second phase began after the September 1954 elections and continued in the mid-1960s. This period was politically marked by the union with Egypt (1958-61) and the beginning of the Baath Socialist regime in 1963. The union era was economically significant.

cant for its lack of expansion in all sectors. Potential investors remained cautious and the resulting uncertainty about the future encouraged the expatriation of profits. The new government wrote a ten-year plan, but by the time it was ready, Syria had seceded from the union.

By July 1965 the Baathist government had gained control of 95% of industrial production, 50% of the value of commercial transactions, and 15% of agricultural production as measured by land ownership. Imports and exports were nationalized and prices fixed for major agricultural products. Economic planning played an increasingly important role with the Five-Year Plan (1960-65) which envisaged an expenditure of \$£2,720,000,000. However, because of political changes and lack of project studies this plan, frequently modified, was less than half fulfilled. A second plan (1965-70) called for total investments of \$£2,780,000,000 of which local finances were to provide 55.6%, foreign borrowing and grants the remainder. Planning priorities in order of emphasis were: agriculture and irrigation; industry, mines, and oil; transport and communication; housing, health, education, and public administration.

**1. Agriculture.**—Although agriculture's share of the national income has declined at an average rate of 1% per year since 1955, it remained in the 1960s the basis of the Syrian economy. Wheat was the chief earner of foreign exchange until the early 1950s when medium staple cotton replaced it. The reasons for agricultural predominance lies in the relatively underpopulated nature of the country and mechanization which has brought increasing productivity per man and high net returns. Cultivable land—more than 30,000,000 ac. (12,000,000 ha.)—is Syria's prime national resource. Capital for the land development came from profits gained from supplying Vichy and Allied forces during World War II. The Baath government started a number of collective farms in the Ghutah and Hamah areas which were orchard and livestock operations confiscated under the Agrarian Reform decrees.

**Land Reform.**—A main effect of the Agrarian Reform decrees of 1958 was the withdrawal of capital and management and reduction of private investment. A secondary effect was the encouragement of peasant initiative. After amendment the law in June 1963 regulated the maximum area of ownership according to location and type of water available. Maximums for holdings varied from 37 ac. (15 ha.) in the densely populated Ghutah area around Damascus to 750 ac. (300 ha.) of nonirrigated land in Al Jazirah. More than 3,400,000 ac. (1,375,000 ha.) were confiscated from 2,770 owners. The sizes of lots distributed to new owners were chiefly conditioned by the size of the family but limited to a maximum of 75 ac. (30 ha.) of nonirrigated land or 20 ac. (8 ha.) of irrigated or tree-planted land. Confiscated but non-allocated land that otherwise would remain idle was rented to anyone who could farm it and liberal credit was granted by the nationalized banks to finance the purchase of farm materials. The authorities were totally unprepared during the drought years

(1958-60) which placed a heavy burden on finances, but by the mid-1960s they began to make available improved seed and fertilizer, as well as undertaking the training of a small cadre of extension agents to improve cotton yields.

**Crops.**—The variable rainfall and temperature conditions produce a wide range of agricultural products. High quality medium staple cotton, the American coker wilt variety, is the nation's major and most reliable export. In years of good rainfall exportable surpluses of wheat can total more than 500,000 tons; domestic consumption is about 700,000 metric tons. Barley exports sometimes reach 400,000 tons; consumption is about 300,000 tons. Lentils, a major food crop often used in rotation with grains, are not exported. Sugar beets were introduced in the early 1950s, but because of poor prices and an arid climate which accelerated dryness they have not proved popular. Vegetables are grown for local consumption, but imports are still required from Lebanon. Increased security in the countryside has encouraged experienced farmers to invest in tree crops. Citrus has expanded sharply in the coastal region. Olives, grapes, and apples are more suited to higher altitudes and rocky soils. The Baathist government has attempted to revive the silkworm industry which thrived prior to the 20th century. The brocade factories now import silk from East Asia. The high-grade tobacco of Latakia meets domestic needs and has an export market; production exceeds 7,000 tons. The Tobacco Monopoly Board licenses cultivators.

**Irrigation.**—The area under irrigation in the mid-1960s, estimated at 1,500,000 ac. (600,000 ha.), has been extended by private pump installations for cotton growing. Extensive ground water and river supplies were being tapped. The chief government irrigation schemes are the drainage of Al Ghab Valley marshlands (begun by the French) to reclaim and irrigate 74,000 ac. (30,000

(TOP LEFT) HERBERT LAUKS FROM BLACK STAR; (TOP RIGHT) DIANE RAWSON—PHOTO RESEARCHERS, INC.; (BOTTOM LEFT) MARIE J. MATTHEWSON—BLACK STAR; (BOTTOM RIGHT) BILL TRACY—PHOTO RESEARCHERS, INC.

ha.) and the Sind area of 25,000 ac. (10,000 ha.). The Sind went into operation in 1965. Five smaller schemes are projected. Although more than \$20,000,000 had been spent on the Euphrates Dam pilot studies and a contract awarded to the U.S.S.R., the government indefinitely postponed the project in 1965.

**Livestock.**—Sheep raising which declined with the cultivation of grazing areas has begun to increase. Water wells, initially dug in Al Jazirah to settle the Bedouin, are now utilized by herdsmen. Recurring droughts reduced herds as farmers sold sheep to buy subsistence needs, but by the mid-1960s the small farmers, with their increasing incomes, tended to buy animals if their income surpluses were not sufficient to buy land. The sheep population exceeded 5,000,000. There was an improvement in poultry production (with American varieties) and cattle breeding (with imported dairy herds from Denmark). All livestock except camels, have increased considerably since the prewar period.

**Forestry.**—The forest area, much reduced since Phoenician times, is less than 168,000 ac. (70,000 ha.) and is concentrated in the pine-covered mountains north of Latakia. There are reforestation programs for planting hillsides and goat raising has been outlawed to prevent damage to the seedlings. Poplar trees planted along irrigation ditches are harvested after 12 to 15 years and bring a good return at no cost since seedlings are free and the water would otherwise be lost through seepage. Poplars are used for building construction, though most of the nation's timber needs are imported.

**2. Fisheries.**—Although the country borders the Mediterranean, the coastal peoples prefer agriculture and especially fruit and tobacco growing to fishing. In the mid-1960s the imports of fish, crustaceans, and mollusks were 2,500 metric tons, three times the amount exported. The amount of local production is unknown. Lack of refrigerated transport and storage facilities have prevented the possible development of the large inland markets.

**3. Industry.**—Light industry has expanded due to high protective tariffs and the availability of cotton and food products which require processing. Traditional handicrafts, such as carpet weaving, leather making, glass blowing and the renowned silk embroidery and brocade (damask) work of Damascus were reviving in the city *sugs* (market places) in response to the tourist demand. In scattered villages domestic industries, particularly the making of camel and goat hair cloth, felt, and rope were declining. The main manufactured items are textiles, canned foods, sugar (Homs), plate glass (Aleppo), cement, oil products, and cigarettes. Output of electrical power in the mid-1960s exceeded 500,000,000 kw-hr. Ammonia, nitric acid, and nitrate dolomite plants were constructed in the 1960s by Italian, Soviet, and Czech contractors.

In December 1964 the government nationalized the largely undeveloped oil and mineral resources. This was followed in 1965 by widespread nationalization of industries and business properties. Virtually all concerns that employed more than 12 persons were confiscated; foreign owners were pledged a negotiated settlement.

**Minerals.**—There are widely distributed but undeveloped deposits of phosphates, lead, copper, antimony, nickel, chrome, and gypsum. Sodium chloride and bitumen deposits are being developed. However, petroleum, discovered in the mid-1960s, may have greater economic potential. Production from oil fields which border the Tigris River is expected to reach 3,000,000 tons by 1970, but the high sulfur content may deter foreign buyers.

The government-owned oil refinery with a capacity of 750,000 tons at Homs, built by a Czech firm, came into operation in 1959, and its output helps to cover Syrian requirements. (Domestic consumption of petroleum products in the 1960s averaged 1,000,000 metric tons annually). The refinery was being redesigned to double its output and to crack the high sulfur crude oil discovered in 1958 at Karachuk where reserves are estimated at 150,000,000 tons. A British consortium was building a pipeline to carry the crude oil to Homs. The Iraq Petroleum Company has constructed pipelines from Kirkuk (Iraq) to the ports of Baniyas and Tripoli (Lebanon). A pipeline from Saudia Arabia to the port of Sidon (Lebanon) also crosses southern Syria. Transit fees on pipeline oil represent a considerable source of foreign exchange.

**4. Foreign Trade.**—In the mid-1960s trade expanded as imports continued to outpace exports. There was a regular deficit which was largely corrected by oil transit royalties and emigrant remittances. Cotton usually accounted for nearly 50% of the value of exports even when grain harvests were good. The value of exports exceeded \$4670,000,000 annually and imports (mainly industrial raw materials and manufactured articles) exceeded \$4900,000,000. China was the largest importer after Lebanon. The Federal Republic of Germany, the United Kingdom, and the United States were the largest exporters.

**5. Finance.**—The unit of currency is the Syrian pound (\$1.00 divided into 100 piastres, and stabilized (for official transactions, at \$43.56 (purchase) and \$43.58 (sale) to the \$ U.S., and at \$410.75 to the £ sterling). The open market rate is approximately \$44.00 to \$1.00. There are three budgets: an ordinary budget (revenue derived mainly from taxation and oil royalties, with expenditure mainly on education and defense); a development budget ( earmarked for agricultural, irrigation, industrial, and transportation projects); and an autonomous budget (to handle increased costs of administering nationalized industries, universities, etc.). In the mid-1960s ordinary budget receipts exceeded \$700,000,000, about 20% came from direct taxes and about 30% from indirect while income from oil transit fees accounted for roughly 17%. By the mid-1960s international loans and aid agreements were increasingly significant. The banks, nationalized by the Union government in 1959, were renationalized in 1963 by the Syrian government. The Central Bank of Syria has assumed management of the commercial banks. The credit needs of large-scale agriculture are served by the Agricultural Co-operative Bank. Credit is paid mainly in kind in cooperation with the Grains Bureau.

**6. Transport and Communications.**—Communications are improving to meet modern demands. There are three railways, built under the Ottoman Empire. The Northern Line (the route of the "Taurus Express") leaves Syria northwest of Aleppo, passing northward into Turkey, where it follows the Turko-Syrian frontier before reentering Syria, crossing Al Jazirah region via Al Qamishli (Kamishli), and entering Iraq at Tall Kujak, to proceed to Mosul and Baghdad. The Hejaz Railway (narrow gauge) runs from Damascus to Ma'an in Jordan. The Damas, Hamah et Prolongements Railway (formerly French, now nationalized) runs on standard gauge from Aleppo to Hamah, Homs, and Tripoli, to continue south along the Lebanese coast. At Homs another line runs into Lebanon to Rayaqa, where it connects with the little-used narrow-gauge line connecting Beirut with Damascus. Because of poor connections freight traffic has increased slowly, while passenger traffic has declined in favour of road and air transport.

Main roads are: (1) Damascus-Homs-Aleppo; (2) Damascus-Qunaytarah; (3) Damascus-Suwayda'-Dar'a and thence to Amman and Baghdad. All-weather roads connect Aleppo with Dayr az Zawr, Al Qamishli, and Ras al 'Ayn, and Damascus with Palmyra. The main desert road from Damascus to Baghdad, 540 mi. (870 km.), passes through the Iraqi frontier post of Ar Rutbah; it carries considerable passenger and freight transport.

There are three ports, Latakia, Baniyas, and Tartus; Baniyas is used only to ship oil from Iraq. Latakia, which has a deep-water harbour (completed 1959), handles the bulk of Syrian trade.

International airlines call mainly at Damascus Airport. Middle East Airlines serves Aleppo and Syrian Arab Airways provides internal and European services.

The Syrian Arab Republic Broadcasting Directorate in Damascus transmits in Arabic, French, and English, and includes Hebrew, Spanish, and Portuguese in its foreign programs. A television service was inaugurated in 1960.

**SYRIAC LANGUAGE** belongs to the Eastern Aramaic group of the Semitic languages (*q.v.*). Since the name "Aramaic" came to mean "pagan," the Greek name "Syrian" or "Syriac" was adopted by the inhabitants of that region. It was the language of Edessa, present-day Urfa, in southeastern Turkey. Edessa became a centre of Christianity at the end of the 2nd century and the intellectual metropolis of the Christian Orient. As a result, the neighbouring Aramaic Christians adopted Syriac. Since the 4th century A.D., because of theological differences, Syriac-using Christians have been divided into Nestorians, or East Syrians, under the Persian sphere of influence, and Jacobite (Monophysites), or West Syrians, under the Byzantine sphere. The Nestorians were excluded from Edessa and settled in Nisibis in Persia.

These two groups became linguistically distinguished by certain differences of pronunciation, chiefly in the vowels. Thus, the Jacobites have *ō* instead of *ā*, *i* and *e* became confused into *i*, whereas *ō* and *ū* both became *ū*. The script likewise became differentiated.

**Writing.**—The earliest Syriac inscriptions (on stone) belong to the first half of the 1st century A.D. and to the second half of the 2nd century. The earliest extant documents not inscribed on stone date from A.D. 243 and come from Doura-Europos, Syria. The early Syriac script was an offshoot of a cursive Aramaic script. The script reads horizontally from right to left. The Syriac alphabet consists of 22 letters, all of them having consonantal values.

The order of the letters in the alphabet is the same as in Hebrew, but the names of some of them are slightly different; thus, *alaph* (Syriac), *aleph* (Hebrew); *gamal* (Syriac), *gimel* (Hebrew); *semkath* (Syriac), *samek* (Hebrew). The majority of the Syriac letters have different forms depending upon their position in a word, whether at the beginning, middle, or end, and whether they stand alone or joined to others. As in other Semitic languages, the consonants ' (*alaph*), *w*, and *y* were originally employed to express vowel sounds.

A highly developed vocalic system was introduced in the beginning of the 8th century. Three main vowel systems developed using a combination of small Greek letters and of dots placed above and below the letters. The most important variety of the Syriac scripts is "estrangelo," derived probably from *satar angelo*, the "evangelic" writing. After the schism in the church, the Syriac language and script split into two branches. The western *sera* or *serto* ("linear") developed later into two varieties, the "Jacobite" and the "Melchite." The eastern branch, called Nes-

torian, had greater importance in the history of writing. When Arabic became the speech of daily life, it was sometimes written in Syriac script; the term for it is *karshuni* or *garshuni*, but its meaning is uncertain.

**Phonology.**—The consonant phonemes of Syriac are: labials *p, b, m, w*; dentals and sibilants *t, d, ṭ, ṣ, s, z, ṣ*; liquids *l, n, r*; palatals and velars *k, g, q*; laryngeals ' , *h, ḥ, ʿ*. The stops *b, p, d, t, g, k* become spirant *ḅ, ḇ, ḏ, ḡ, ḱ* if they are preceded by a vowel. The vowels are *a, ā, e, ē, i, ī, o, ō, u, ū*, and a very short *ē*. The diphthongs are *aw, ay, āy* (Western Syriac *ōy*), *ēw, iw*. No syllable can begin with a vowel. All the consonants except *h, ʿ* and *r* can be geminated (or long) in medial position. Gemination does not occur either initially or finally. There is no gemination in Western Syriac.

A few cases of partial and total assimilation as well as of metathesis occurring with the morpheme *t* of the reflexive-passive stem should be mentioned here. Metathesis occurs in the combination *tš, ts* becoming *št, st*; thus *ʿeštamlī* for *ʿetšamlī* "it was accomplished," *ʿestēged* for *ʿetsēged* "he was worshiped." Metathesis and partial assimilation occur in *ts, tš* becoming *zd, št*; thus *ʿesdēqēp* for *ʿetzeqep* "he was placed upright," *ʿesṭēleb* for *ʿetšēleb* "he was crucified." Total assimilation occurs in the succession *t-ʿ* becoming *tt* and *t-d* becoming *dd*; thus *ʿettaqtal* for *ʿetʿaqtal* "he was killed," *ʿettašše* for *ʿettašše* "hide me," *neddakrak* for *nētdakrak* "he remembers you." Likewise *n* as first radical of the root is assimilated to any consonant with which it is in contact: *ʿappeq* for *ʿanpeq* "he brought out."

**Morphology.**—Syriac has a set of independent personal pronouns used for the expression of the subject, and a set of shortened forms suffixed to the nouns and to the verbs. With the verb they express the direct complement, occasionally the indirect complement; with the noun, they express the possession. The forms of the nouns and of the verbs with the suffixed pronouns very often change their syllabic structure.

The noun has three states, an absolute, a construct, and an emphatic state. The absolute state is the pure stem and is used mainly for adjectival and participial predicates. The construct state has as a rule the same form as that of the absolute state and is used in the expression of possession (*mēlēk ʿālmā* "the king of the world"). The emphatic state has the suffixed element *-ā* of the article, but lost its determined value so that *malkā*, originally "the king," came to mean "king."

There are two genders in Syriac, masculine and feminine. The mark of the feminine is the suffixed *-t*. Its form is *-at* with a noun in the construct state (*biš-at*), *-ētā* with a noun in the emphatic state (*biš-ētā*), and *-ā* in the absolute state (*biš-ā*). Several noun classes (animals, plants, parts of the body, utensils) are treated as feminine without having the feminine ending *-t*.

Syriac has two numbers, singular and plural. The forms of the plural are: for the masculine, absolute state *-in* or *-ēn* (*biš-in*), construct state *-āy* (*biš-āy*), emphatic state *-āy(y)ā*, mostly contracted into *-ē*; for the feminine the forms are, absolute *-ān*, construct *-āt*, emphatic *-ātā*.

**The Verb.**—There are biradical, triradical, and quadriradical verbs, the majority being triradicals. The basic stem of the regular triradical verb has the forms *qētal* (mostly transitive), and *qētel* (mostly intransitive). The verbs that have a first radical *w, y, n* or laryngeals as 1st, 2nd, or 3rd radical have different syllabic structures in the various tenses of the verb. The biradicals are of the types *qām, baz* (*z*), and *rēmā*, whereas the quadriradicals have the form *qartel*. The derived stems are *qattel* (with geminated 2nd radical), serving mainly for the expression of the intensive (occasionally causative), and *ʿaqtel* (with the prefix *ʿa-*) for the causative. All these stems can form a passive-reflexive mood with the prefixed morpheme *ʿet*, the forms being *ʿetqtel* (from *qtal, qtel*), *ʿetqattel* (from *qattal*), and *ʿettaqtal* (from *ʿaqtel*).

There is a considerable number of Syriac verbs having the prefix *ša-* (*šaqtel*) for the expression of the causative, and *qatqat*

(that is, a repeated biradical root) for the expression of the frequentative.

The past is expressed by the "perfect," which is formed by suffixed morphemes (thus, \**kētab* "he wrote," \**kētabū* "they wrote"). Habitual or continuous action in the past is expressed by the active participle followed by the perfect of *hēwā* "he was" (thus *dāhel hēwā* "he was fearing"). The future is expressed by the "imperfect" formed by prefixes or suffixes or both (thus, \**nektūb* "he will write," \**nektēbūn* "they will write"). The present is expressed by the active participle followed by the personal pronoun, mostly in contracted form (thus \**kāteb 'at* or \**kātbat* "you write").

The expression for the 1st person is common for the masculine and feminine, whereas for the 2nd and 3rd persons there are special forms for the masculine and feminine. Note that the prefix of the imperfect 3rd person is *n*, against *y* of the other Aramaic dialects.

Like all the other Semitic languages Syriac has no verb "to have." The idea of possession is expressed by the verb *'it* "there is, there are" followed by the indirect complement (thus *kēmā lahmīn 'it lēkūn* "how many loaves of bread do you have?" literally "how-many breads there-are-to-you?").

The Syriac vocabulary is basically Semitic. Among the loanwords are some Hebrew words in the domain of religion and some Persian words from translations of Persian, but the great majority of loanwords are Greek. See also SYRIAC LITERATURE.

(1955).

(W. LÜ.)

**SYRIAC LITERATURE**, literature written in Syriac by Syrian Christians until the language was finally superseded by Arabic in the 14th century A.D. Apart from its obvious interest to Semitic scholars, Syriac literature is of importance for the study of Syrian Christianity, for the fact that it preserves many translations of Greek Christian texts which have not survived in their original language, and for its role as an intermediary between ancient Greek learning and the Islamic world.

**Historical Survey.**—Syriac, one of several Aramaic dialects, was used in Edessa (*q.v.*) and Osroene (Osroene), its province, from about the 1st century B.C. (see SYRIAC LANGUAGE). The language was invigorated after the introduction of Christianity. The active Christian communities in Syria, Mesopotamia, and Persia instilled such life into the literary culture that Syriac literature surpassed all other Aramaic literatures in both its geographical extent and the variety of its character and historical significance. Its great range may be seen from inscriptions, which have been found as far south as India (also the so-called Indian crosses), as far east as China (the Chinese and Syriac inscription of Si-ngan-fu of 781), and as far north as Turkistan (monuments in the cemetery in Semirechye, Kazakh S.S.R.).

Literary creation in Syriac during the centuries was naturally influenced by the events of history. The christological controversy in the middle of the 5th century brought about the separation of the Syrian Christians from the Christians of the Byzantine Empire and the Western world who accepted the Council of Chalcedon in 451 (see COUNCIL). Also the Syrian Christians themselves became divided into the Monophysite West Syrians, called Jacobites (see ANTIOCH, SYRIAN ORTHODOX PATRIARCHATE OF), and the Nestorian East Syrians (see NESTORIANS). These events, so unhappy in their results for church history, did not cause retrogression from the point of view of literary creation. Indeed, they even brought incentives in the form of new themes.

Other great events which determined the fate of Christians in the Orient affected literary life also. The Arab conquest in the 7th century, which altered the political scene almost overnight, did not bring much change into the life of Christians under the Omayyad caliphs (660–750). Deeper changes were felt under the Abbasids from 750 onward. But when Arabic was made the current vernacular, an epoch was initiated which gradually and con-

sistently began to affect the use of Syriac. Later there were Syrian authors who wrote in both Arabic and Syriac. The chaotic circumstances attending the disintegration of the caliphate toward the end of the 10th century were not favourable to literary creation. The invasion of the Mongols in the 14th century destroyed Syrian Christianity and brought Syriac literature to an end except for an insignificant aftermath.

**Versions of the Bible.**—Proof of the Syrians' exceptional interest in and solicitous care for the preservation of the Bible lies in the fact that no other Christians in the ancient or mediaeval period produced so many different versions as they did. Besides the Diatessaron (*q.v.*) there were at least ten different versions of the Old and New Testaments. Besides these there is a tradition, unsupported by any surviving fragments, about a version of the Old Testament prepared by Catholicos Aba (d. 552).

Modern studies have led to new discoveries about the history of the biblical text. An observation made first by F. Perles, that the Old Testament Peshitta must have had some connection with the Targums, has found proper recognition by A. Baumstark, followed by C. Peters. Their studies show that the ancient Palestinian Targum was carried over into the East Aramaic language (see TARGUM). But the targumic substructure is far greater than that which has been found in the editions of the Peshitta text. New data have come to light which give a new perspective to the relation of the Peshitta to the Targums. The new material shows that superficially revised or even unrevised manuscripts continued to exist, and, as those codices were multiplied, the influence of the Palestinian Targum continued to be felt in the ancient Syriac Bible, particularly in the Pentateuch, the Prophets, and the Psalms, long after the revised version called the Peshitta was made.

The New Testament studies of D. Plooij and A. Baumstark strengthened the view that Tatian (*q.v.*) composed his Diatessaron in Syriac, not Greek. Therefore the earliest form of the Gospels in Syriac was the harmony, not the four separate Gospels. Entirely new and unexpected light has been shed upon the earliest history of the Gospel text. The new materials about the Old Syriac version of the Gospels necessitate a reorientation in the understanding of the history of the text. The Diatessaron was officially discouraged much earlier than was previously thought. The Peshitta is not, as was once believed, the work of Bishop Rabbula (*q.v.*). The remnants of his text that have come to light show that it was a type of the Old Syriac recension. Although the New Testament Peshitta originated before Rabbula it gained ground very slowly. The Old Syriac text type was not a "library copy" but a text which in different forms continued to exercise its influence even centuries after Rabbula.

New light has also been shed on the version prepared by Thomas of Harcel in 615–616. The old controversy whether Thomas revised an earlier version prepared by Bishop Polycarp for Philoxenus (*q.v.*) of Mabbug or only copied Polycarp's version and furnished it with the textual critical apparatus has finally received a solution; portions of Polycarp's version identified in Philoxenus' commentary on John show that in the process of revision Thomas carried Polycarp's work farther.

New text materials have been published in A. Vööbus, *Peshitta und Targumim des Pentateuchs* (1958); *Studies in the History of the Gospel Text in Syriac* (1951); *Early Versions of the New Testament* (1954).

**Poetry.**—The earliest hymnographers of Syriac literature were the Gnostic Bardesanes (*q.v.*; 154–222) and Aswana (4th century), whose writings have not survived. The works of Ephraem Syrus (*q.v.*; 4th century) thus stand at the beginning of Syriac literature and were never surpassed by any later author. Two poetic forms were employed by him, the *mēmra* and the *madrāšā*. The *mēmra* is designed to touch the ear not as song but as spoken speech in metrical form, whether a narrative or didactic epic; it is in fact a metrical homily. A *madrāšā* is a more artful composition, composed in strophes and sung by a choir or double choir. Little has survived of the poetry of Qyrrillona, a contemporary of Ephraem, or of Balai (d. after 432), whose themes and form show great variety. Some elegant poems ascribed to Balai

found their way into liturgical books. The authenticity of many of the *mēmre* ascribed to Isaac (q.v.) of Antioch (5th century) is uncertain. Among the West Syrians the place of honour belongs to Jacob (q.v.) of Serug, whose *mēmre* on a variety of church and biblical subjects are superior to those that have come down under Isaac's name. Jacob's poetry was never surpassed by any later author.

At the beginning of Nestorian Christianity stands Narsai (d. c. 503), author of many *mēmre* and the greatest poet of the East Syrians. The elegance of his poetry and the beauty of his style earned for him the reputation of the "harp of the Holy Spirit." The poetry of Elisha bar Quzbaye, Abraham of Bet Rabban, and Abraham bar Qardahe (all of the 6th century) is no longer extant. In the 13th century Giwargis Warda and Khamis bar Qardaha wrote hymns that were included in the liturgy. Abdisho bar Berikha (see ABHDISHO BAR BERIKHA) of Nisibis wrote "Paradise of Eden," a collection of 50 metrical homilies.

Editions and translations of Syriac poets are as follows: Balai, ed. by K. V. Zetterstéen with German translation (1902); Isaac of Antioch, edited by P. Bedjan (1903); Jacob of Serug, edited by P. Bedjan, 5 vol. (1905-10); Narsai, edited by A. Mingana, 2 vol. (1905); and Abdisho, "Paradise of Eden," partially ed. by H. Gismondi with Latin translation (1888).

**Translations from Greek.**—The Syrians began their literary activity by making Greek Christian writings available in Syriac. Almost all the important authors and documents of Christian Greek were translated by the Syrians, the resulting mass of material being so great that space forbids even the naming of selected works. Translating, which continued for centuries to be part of Syrian literary life, must have received an important incentive from the school of Edessa as early as its director Qyore in the first part of the 5th century (see EDESSA: *Edessene Christianity*). Its best-known translators were Hiba (Ibas; d. 457), known to tradition as "the translator," and his contemporaries Proba and Kumi. Such a lively centre of learning as Edessa remained until the closing of the school in 489 must certainly have provided stimuli for other educational centres, particularly those where former scholars of Edessa took up their residence. Teams of translators as well as individuals must have had their share in the work. Among later translators the best known are Paul of Callinicos (6th century), Paul of Edessa (7th century), the patriarch Athanasius II of Balad (d. 686), and Jacob (q.v.) of Edessa.

This Greco-Syrian translated literature is an essential source for works of Greek Christian literature that have not survived in their original language. An obvious example of this is the earliest dated Syriac manuscript (Ms. Brit. Mus. Add. 12,150), from the year 411. It includes four works originally written in Greek: Titus of Bostra's treatise against the Manichees, Eusebius (q.v.) of Caesarea's *Theophania*, the Pseudo-Clementine *Recognitions*, and Eusebius' account of the martyrs of Palestine. The first two of these survive in Syriac only, the third in a Latin translation also, and of the last only a part has survived in the original Greek.

The translators also put into Syriac most of the works of Aristotle and other ancient Greek philosophers, together with the writings of the chief medical and scientific authors of ancient Greece. These translations formed an important preparatory work for the rise of Islamic civilization. It was much easier to translate from Syriac into Arabic than directly from Greek into Arabic; thus, for instance, to take the works of Galen alone, 130 were translated into Arabic from Syriac and only nine directly from the Greek original into Arabic. For this reason many works of Greek learning exerted their influence on the Muslim world through the medium of Syriac.

**Biblical Commentaries.**—The earliest example of Syrian exegesis is the homilies of Aphraates (q.v.). The Syriac tradition of commentaries begins with Ephraem Syrus, who composed a series of them. Much of the exegetical work produced after the doctrinal separation is lost. Little remains of the commentaries by Philoxenus on the Gospels.

The great authors who carried on these traditions are con-

nected with Edessa. Jacob of Edessa produced important scholia. In the mountains near Edessa in the 8th century, Lazar of Bet Qandasa compiled his commentary on the New Testament, based on earlier authors (Ms. Brit. Mus. Add. 14,683), and in 861 the monk Severus in the convent of St. Barbara completed an extensive commentary (Ms. Vatican syr. 103) based on Ephraem and Jacob of Edessa. Several centuries of sporadic exegesis were followed by the major commentaries on the Old Testament and the New Testament compiled in the 9th century by Moshe bar Kepha (Ms. Brit. Mus. Add. 17,274, Ms. Oxford Bodl. orient. 703, and Ms. Mardin 101/4 and 102/4), in the 12th century by Dionysius Bar-Salibi (see BAR-SALIBI, JACOB), and on the Old Testament in the 13th by the learned Bar-Hebraeus (q.v.).

Most of the exegetical works of the East Syrians are lost; only fragments survive from Mar Aba, John of Bet Rabban, Michael Badoqa, Henana, and Sabrisho bar Paulos. An idea of the extent of this work is given by an anonymous work written c. 900 (Ms. Birmingham Ming. syr. 553, Ms. Vatican syr. 578, and Ms. Chald. Patr. Baghdad 112 and 113) which is a repertory of the East Syrian exegetical tradition. The commentaries of Ishodad of Merv (9th century) are among the best produced by the Nestorians and had some influence on West Syrian exegesis. The most extensive of his Old Testament commentaries is that on Genesis; his commentary on the New Testament is also important. The *Gannat büssamē* ("Garden of Delight"; Ms. Diyarbakir 29 and Ms. Berl. orient. quart. 870), a work of the 13th (?; according to J. M. Vosté of the 10th) century, is a rich source of extracts from the older exegetical tradition.

Editions and translations of Syriac biblical commentaries include: Aphraates, ed. by I. Parisot, *Patrologia Syriaca*, vol. I, 1-2 (1894-1907); Jacob of Edessa, ed. by G. Phillips with English translation (1864); commentaries on the Old and New Testaments compiled by Dionysius Bar-Salibi, ed. by I. Sedlaček, J. B. Chabot, and A. Vaschalde, with Latin translations, *Corpus Scriptorum Christianorum Orientalium: Series Syriaca* (referred to hereafter as *CSCO syr.*) II, 98-99, 101 (1906-40); Bar-Hebraeus on the Old Testament, ed. by W. E. W. Carr with English translation (1925); Ishodad of Merv, commentary on the Old Testament, ed. by J. M. Vosté and C. van den Eynde with French translation, *CSCO syr.* II, 67, 75, 80, 81, 96 (1950-63), and commentary on the New Testament, ed. by M. D. Gibson with English translation in *Horae Semiticae*, vol. 5-7, 10 (1911-16). Regarding the role of the school of Nisibis in hermeneutic literature, see A. Vööbus, *History of the School of Nisibis* (1965).

**Acts of the Martyrs and Lives of the Saints.**—Narratives form a large group in the Syrian literary creation. To cast into the mold of a tale the history of the saints was a favourite art of the Syrians. The earliest documentary evidence leads to Edessa, where in the late 4th century the acts of Sharbil and Barsamya, martyred under Decius, and of Gurya and Shamona, martyred under Diocletian, were composed. These were followed by a long series of similar documents about the martyrs persecuted in Persia under Shapur II in the 4th century and augmented by those about the victims of later persecutions. Among this material is a collection covering the period from Shapur II to Bahram IV and concluding with an epilogue explaining the structure and extent of this ancient source, which according to the intrinsic evidence must have been composed before 399. This work has been ascribed to Maruta, bishop of Maipherqat (Martyropolis), but this is pure speculation. Another collection, the Miles trilogy, is somewhat later.

When the persecutions ceased, the theme for narratives was found in the lives of ascetics, monks, and saints. The disciples of the monks in particular felt the need of paying homage to their monastic teachers by way of panegyrics, encomiums, and biographies. The annual commemoration in the monasteries also stimulated this kind of literary production. Among the many lives are some particularly valuable as historical sources. The earliest of these among the West Syrians is the biography of Bishop Rabbula of Edessa, written shortly after his death by one of his clergy.

The life of John bar Qursos (d. 538) was written by his disciple

Eliya after 542. The life story of John bar Aphthonya (d. 537), founder of the famous monastery of Qanneshre, is the work of an anonymous disciple. The biography of Maruta, metropolitan of Tagrit, was written by his successor, Denha (d. 660). Lives of the Eastern saints by John (q.v.) of Asia, bishop of Ephesus, written after 566, dealing with the monasteries and their inmates around Amida (modern Diyarbakir), is an excellent historical source.

Among the East Syrians outstanding examples are: the biography of Catholicos Aba written by an unknown admirer; another of Catholicos Sabrisho I (d. 604) by a monk Petros; an extensive life of Hormizd, the founder of a monastery at Alqosh which still survives, written by a monk Simeon; and the story of Ishosabran, martyred in 620, written by Ishoyahb III, who later became catholicos. Among the authors who produced this genre of writings the most eminent is Babai the Great (d. after 627), abbot of the Izla monastery, whose enormous literary production consisted in a great part of such works; biographies of the martyred monk Giwargis (d. 612) and the martyr Christina are the only examples that have survived. Much literature of this kind must have been in circulation, including many works that are purely legendary in content. Yet there survives a great bulk of documents whose authors with differing degrees of success exercised their first steps toward putting their eulogies into a framework of history, whether ecclesiastical or secular.

Editions and translations of works in this class of literature include: collection of acts of Persian martyrs attributed to Maruta, ed. by P. Bedjan, *Acta martyrum et sanctorum* (1890-97); biography of Rabbula, ed. by J. J. Overbeck, *S. Ephraemi Syri, etc., opera selecta* (1865), German translation by G. Bickell, *Bibliothek der Kirchenväter*, no. 103-104 (1874); Eliya's life of John bar Qursos, ed. by E. W. Brooks with Latin translation, *CSCO syr.* III 25 (1907); anonymous life of John bar Aphthonya, ed. by F. Nau with French translation (1902); Denha's biography of Maruta, ed. by F. Nau with French translation, *PO* 3 (1905); biographies of Aba and Sabrisho I, ed. by P. Bedjan (1895); Simeon's life of Hormizd, ed. by E. A. W. Budge with English translation (1894-1902); Ishoyahb III's story of Ishosabran, ed. by J. B. Chabot, *Nouvelles archives des missions scientifiques et littéraires*, 7 (1897); Babai's biographies of Giwargis and Christina, ed. by P. Bedjan (1894-95).

**Historical Works.**—The earliest Syriac historical work is the *Chronicle of Joshua*, written in 507 by an unknown monk in Edessa who described the events of the years 495-507 in Edessa, Amida, and Mesopotamia. It owes its survival to the fact that it was included much later in a historical compilation attributed to Dionysius of Tell Mahre (see below). The *Chronicle of Edessa*, written later in the 6th century, is a valuable source, although limited in extent. Its account, which at first is too lapidary but becomes somewhat fuller toward the end, covers 132 B.C.-A.D. 540. Among works produced during the following centuries, some stand out because of their extent and the wealth of their information. John of Ephesus (Asia) toward the end of his life completed a church history in three parts, of which only the last, covering the years 572-585, has survived. An anonymous work under the name of Zacharias Rhetor contains in books 3-6 a translation of a lost work written in Greek by Zacharias Rhetor; books 1-2 and 7-12 are a compilation of a monk in Amida.

The two earliest important chronicles produced during the Islamic period were those of Jacob of Edessa, preserved only partly, and an anonymous work, wrongly ascribed by J. S. Assemani to Dionysius of Tell Mahre, which c. 775 emanated from the monastery of Zuqin (see DIONYSIUS TELMAHARENSIS). Dionysius did write a historical work, in 16 books covering 582-842, but only a fragment survives. However, it has survived in the following two great chronicles which mark the end of the West Syrian annalistic tradition. A monumental chronicle in 21 books by the patriarch Michael I (d. 1199) covers church history, secular history, and other events in three parallel columns, up to 1195. Michael's work, influenced by the chronicle of Jacob of Edessa, is valuable because it incorporates many historical sources and excerpts of documents—it is a veritable depository of lost

documents. An anonymous chronicle later than, but independent of, Michael comprises a secular and an ecclesiastical part, the latter depending frequently on Dionysius of Tell Mahre; it was completed finally in 1233/34. Bar-Hebraeus wrote several historical works, including an ecclesiastical history and a chronography which is in fact a history of the world. His "Chronicle of Dynasties" belongs to Arabic literature.

East Syrian literature displays no parallel to this rich annalistic literature. The earliest chronicle is that by Meshihazekha, composed between 540-551 and known as the *Chronicle of Arbela*. Its information about the oldest period of Christianity in Adiabene is drawn from a still older but lost work, composed by Abel about the middle of the 5th century. A counterpart to the history of the metropolis of Adiabene is that of the metropolis of Bet Garmai "History of Karka de Bet Selok and Its Martyrs," an anonymous work describing the history of the city, its bishops, and its martyrs under the Sasanian king Yazdegerd II; its last redaction belongs to the 6th century, but the original work was written earlier. The church history of Barhadbeshabba of Bet Arbaye belongs to the beginning of the 7th century.

There was little annalistic writing during the Islamic period. The "Various Narratives from Church and World History," by an anonymous monk who describes events from 590 to 680, provides data about the last period of the Sasanian dynasty. It used an earlier work. The church history by John bar Penkaye goes up to 686. The last historical work of the East Syrians is Eliya bar Shinaya's chronicle, written 1019, an important source which includes numerous chronological tables and lists of patriarchs.

The weakness of the East Syrians in this area is partly balanced by the variety of their historical interests, which cannot be paralleled in West Syrian literature. One branch particularly is eminent, created by the interest in the history of schools. Many works were devoted to education, only one of which has survived composed by Barhadbeshabba of Holwan (c. 600), giving an idea of this genre of literature. The East Syrians' historical interest was extended to the history of literature, and the catalogue of Abdisho bar Berikha is an invaluable source of information about Syrian authors and their works. A supplementary branch of study can be seen in the works on the history of monasteries, which also have no counterpart in the literature of the West Syrians. About 840 Thomas of Marga wrote the history of his own monastery of Bet Abe, the "Book of Governors." At about the same time Ishodenah of Basra, whose church history is lost, wrote a work on the founders of the monasteries and the ascetic authors.

Of Syriac historical writing, the following editions and translations are available: *Chronicle of Joshua*, ed. by W. Wright with English translation (1882); *Chronicle of Edessa*, ed. by I. Guidi with Latin translation, *CSCO syr.* III, 4 (1904); John of Asia's church history, ed. by E. W. Brooks with Latin translation, *CSCO syr.* III 3, (1935-36); Zacharias Rhetor, ed. by E. W. Brooks with Latin translation, *CSCO syr.* III, 5-6 (1919-24); Jacob of Edessa, ed. by E. W. Brooks with Latin translation, *CSCO syr.* III, 4 (1904-07); fourth part of the anonymous work ascribed to Dionysius of Tell Mahre, ed. by J. B. Chabot with French translation (1895); chronicle of Michael I, ed. by J. B. Chabot with French translation, 4 vol. (1899-1924); anonymous secular and ecclesiastical chronicle ed. by J. B. Chabot with Latin translation, *CSCO syr.* III, 14-15 (1917-37); Bar-Hebraeus' ecclesiastical history, ed. by I. B. Abbeloos and T. J. Lamy with Latin translation, 3 vol. (1872-77), and chronography, ed. by P. Bedjan (1890); *Chronicle of Arbela*, ed. by A. Mingana with French translation *Sources syriaques*, vol. 1 (1907-08); "History of Karka de Bet Selok and Its Martyrs," ed. by P. Bedjan (1891); Barhadbeshabba of Bet Arbaye's church history, ed. by F. Nau with French translation, *PO* 9, 23 (1913-32); "Various Narratives from Church and World History," ed. by I. Guidi (1891), German translation by T. Nöldeke (1893); John bar Penkaye's church history, ed. by A. Mingana with French translation, *Sources syriaques*, vol. 1 (1907-08); Eliya bar Shinaya's chronicle, ed. by E. W. Brooks and J. B. Chabot with Latin translation, *CSCO syr.* III, 7-8 (1909-10); Barhadbeshabba of Holwan's work on education, ed. by A. Scher with French translation, *PO* 4 (1907); Ishodenah of Basra

ed. by J. B. Chabot with French translation in *Mélanges d'archéologie et d'histoire*, 16:222-293 (1896); catalogue of Abdisho, ed. by A. Vööbus with Latin translation, *CSCO Subsidia* (1966).

**Theology.**—The earliest theological works bear the names of Aphraates and Ephraem Syrus. The time of doctrinal conflict and storm opened new avenues and gave new themes in dogmatics. The man who laid the groundwork of Syriac dogmatics for followers of the doctrine of the one nature of Christ (*i.e.*, the Monophysites) was Philoxenus of Mabbug with his three books on the Trinity and incarnation and ten dissertations on the subject "One of the Trinity Has Become Flesh and Has Suffered." Among the many later theological works, some stand out as special achievements. Among these is the *Hexaemeron*, composed by Jacob of Edessa toward the end of his life, a continuation of a lost book on the question of theodicy entitled "The First Cause." The latter cannot be identified with a work bearing a similar title, the "Cause of Causes," a noteworthy treatise inspired by mysticism and by irenic endeavours toward other religions, presented in an attractive way, which from internal evidence must have been composed at least two centuries later.

In the 9th century the most noteworthy author was the patriarch Qyriaqos (d. 817), who wrote on various theological subjects (Ms. Jerusalem St. Mark's Mon. 129). John of Dara, a distinguished 9th-century theologian, wrote a work in four books about the resurrection of the body; another about the heavenly and earthly hierarchy (Ms. Vatican syr. 100), which is a commentary on Pseudo-Dionysius; a work in eight books about the soul, only partially preserved (Ms. Vatican syr. 147); four books on priesthood; and works on other subjects (Ms. Damascus Patr. 4/4 and 4/5). The prolific Moshe bar Kepha's (d. 903) incomplete work on predestination and free will was cast in at least four books (Ms. Brit. Mus. Add. 14,731), that on the soul in one book (Ms. Vatican syr. 147). His dissertation on paradise in three books was long known only through Arabic translations and a Latin translation made before the original manuscript was lost; this, as well as other works, was discovered in 1965 (Ms. Mardin 368 and 381). The most outstanding apologist was Nonnus of Nisibis (9th century), whose works include a treatise on trinitarian and christological problems. The last to cultivate this genre of literature was Bar-Hebraeus, whose "Candelabrum of the Sanctuary" (Ms. Vatican syr. 168) is a comprehensive exposition of Monophysite doctrine and whose "Book of [Sparkling] Rays" (Ms. Vatican syr. 169) is a more condensed exposé of the same material.

Among the East Syrians, dogmatic works occupy a more modest place. Among the treatises produced by Ishai, Henana, and Thomas of Edessa the most important is "About Union," dealing with the problem of divinity and humanity in Christ's person, a systematic presentation of the Nestorian theological position, written by Babai.

The "Book of Scholia," completed in 791/792 by Theodoros bar Koni in 11 books, is a mélange of exegetical, speculative, theological, and apologetic discussions. The last book is particularly valuable as it contains historical data on various early religious sects from sources now lost. The "Apology" of the catholicos Timothy I (d. 823) is in the form of a discussion with the Caliph al-Mahdi. There is no significant work in this area before Abdisho bar Berikha, of whose theological writings only the *Margaritha* ("Pearl"), the official exposition of the Nestorian doctrine in its last stages, survives.

Editions and translations of theological writings include: Philoxenus of Mabbug, ed. with Latin translation by A. Vaschalde, *CSCO syr. II*, 27 (1907), and by M. Brière, *PO* 15 (1920); Jacob of Edessa's *Hexaemeron*, ed. by J. B. Chabot and A. Vaschalde with Latin translation, *CSCO syr. II*, 56 (1928-32); the "Cause of Causes," ed. by C. Kayser (1889), German translation (1893); John of Dara's four books on priesthood, ed. by A. Hobeica (1911); Moshe bar Kepha's dissertation on paradise reprinted in J. P. Migne, *Patrologia Graeca*, vol. 111, col. 481-608 (1863); Nonnus of Nisibis, ed. by A. van Roey with Latin translation (1948); Bar-Hebraeus' "Candelabrum of the Sanctuary," first two parts ed. by J. Bakos, *PO* 22-24 (1930-33), third part by F. Grafsm, *PO* 27 (1957); Babai's "About Union," ed. by A. Vaschalde

with Latin translation, *CSCO syr. II*, 61 (1915); Theodoros bar Koni's "Book of Scholia," ed. by A. Scher, *CSCO syr. II*, 65-66 (1910-12); Timothy I's "Apology," ed. by A. Mingana with English translation, *Woodbrooke Studies*, vol. 2 (1928); Abdisho's *Margaritha*, ed. by A. Mai with Latin translation, *Scriptorum veterum nova collectio*, vol. 10 (1838).

**Ethics, Asceticism, and Mysticism.**—This genre also begins with Ephraem Syrus, whose whole literary creation is permeated with, and who devoted a series of writings especially to, the ascetic ideal. An anonymous "Book of Degrees," an extensive work in 30 chapters on Christian perfection which mistakenly has been connected with the Messalians (a sect that laid great stress on asceticism and on ceaseless prayer), also dates from the 4th century. A large collection of similar treatises which point to a certain Simeon were discovered by H. Dörries (see below, *Bibliography*).

An extensive mass of writings which centres on the name of John seems to contain also texts of Syriac provenance and not merely translations of writings of John of Lycopolis. Thus cultivation of this genre of literature had a great vogue before the separation of the Syrians, and continued after it.

The West Syrian tradition was greatly enriched by the important contribution of Philoxenus of Mabbug, the chief of whose numerous ascetic writings is his collection of 13 treatises on Christian perfection. His Edessene contemporary Stephanos bar Sudaile, in his "Book About the Hidden Secrets of the House of God," unfolds a mysticism influenced by Origen and pantheistic thinking. Later works in this field do not rise above mediocrity until the last great author, Bar-Hebraeus, who wrote a work on ethics and another on asceticism, "Book of the Dove."

The literature of the East Syrians shows how widely they cultivated asceticism and mysticism. Some of their writings in this field won respect far beyond their own confessional boundaries and even beyond the frontiers of the Syriac language. Babai's commentary on the *Centuries* of the Greek author Evagrius and Sahdona's "Book of the Perfection of Works" commanded wide esteem. Isaac of Ninive (7th century) is of special importance because his conception of mystical life became fundamental to East Syrian asceticism, but all that has survived from his extensive writings is his work in 82 chapters on Christian perfection. Nearly as high a reputation belonged to another 7th-century author, Joseph Hazzaya, whose many works show a wide literary variety (Ms. Birmingham Ming. syr. 601). John of Dalyata, who wrote both homilies and letters on monastic spirituality in the 8th century, was known as the "spiritual old one" (Ms. Cambridge Add. 1999). Other authors prolific in this field in the 7th and 8th centuries were Simeon Taibuteh, Abraham Bardashandad, and Dadisho of Bet Qatraye. Only a corpus of treatises and letters (Ms. Vatican syr. 185) survives from the learned Abdmeshiha of Hirta (9th century).

Editions of works in this genre include: "Book of Degrees," ed. by M. Kmosko with Latin translation, *Patrologia Syriaca*, I, 3 (1926); Philoxenus of Mabbug, ed. by E. A. W. Budge with English translation, 2 vol. (1894); Stephanos bar Sudaile, ed. by F. S. Marsh with English translation (1927); Bar-Hebraeus, ed. by P. Bedjan (1898), English translation by A. J. Wensinck (1919); Babai, ed. by W. Frankenberg with German translation (1912); Sahdona, ed. by A. de Halleux with French translation, *CSCO syr.* 86-87, 90-91, 110-113 (1960-65); Isaac of Ninive, ed. by P. Bedjan (1909), English translation by A. J. Wensinck (1923); about other sources, see A. Vööbus, *History of Asceticism in the Syrian Orient*, I-II (1958-60).

**Civil and Canon Law.**—Much of the canon law of the Greek church was translated into Syriac. The Syro-Roman lawbook, containing decrees of the Byzantine emperors Constantine I, Theodosius I, and Leo I in Syriac translation, was not part of Oriental canon law as practised but was a handbook for instruction. On the foundation of the Greek traditions the Syrians built the traditions produced by their own genius.

With regard to synodical canons the best traditions were kept by the Nestorians. The evidence for this lies in the corpus of synodical acts (*Synodicon orientale*), beginning with the synod

held in 410 in Seleucia-Ctesiphon and ending with those of the year 775. The West Syrians had no corpus of equal extent, though there is a unique manuscript (Ms. Damascus Patr. 8/11) which among legislative documents has preserved a cycle of synodical acts otherwise unknown (Synodicon). Among the rich collections of canons that have survived, a special place is occupied by canons for monasticism. Ecclesiastical law is extant in many collections of canons set up by such West Syrian authorities as Rab-bula, John bar Qursos, Jacob of Edessa, and Giwargis, bishop of the Arabs (d. 724), and by the patriarchs, such as John III (d. 873), Theodosius (d. 896), Qyriacos (d. 817), and Dionysius of Tell Mahre (d. 845). Selected regulations were codified by Bar-Hebraeus in his *Nomocanon*.

Among the East Syrians there are the statutes of the school of Nisibis, the oldest of which date from the year 496. Many church leaders contributed to the canonical materials: Giwargis, metropolitan of Arbela (10th century), and heads of the church, such as Ishoyahb I (d. 596), Sabrisho II (d. 835), and John V bar Abgare (d. 905). Part of the lost collections of canons has been preserved in Arabic translation. Lawbooks were composed by the catholicos Mar Aba I, his later successors Henanisho I (d. 699), Timotheus I (d. 823), and Isho bar Nun (d. 828), and by two metropolitans of Rewardeshir, Simeon (7th century) and Ishobokht (8th century), who originally wrote in Persian, from which they were translated into Syriac. Selected material was incorporated into the *Nomocanon* of Abdisho.

Editions and translations of works of civil and canon law: Syriac translation of Syro-Roman lawbook, ed. by K. G. Bruns and E. Sachau with German translation (1880); *Synodicon orientale*, ed. by J. B. Chabot with French translation (1902); lawbooks by Mar Aba I and his successors, ed. by E. Sachau with German translation, 3 vol. (1912–14); monastic canons, ed. by A. Vööbus with English translation (1960); statutes of the school of Nisibis, ed. by A. Vööbus with English translation (1962); *Nomocanon* of Abdisho, ed. by A. Mai with Latin translation (1838); Bar-Hebraeus' *Nomocanon*, ed. by P. Bedjan (1898), Latin translation by J. A. Assemani (1838); *The Synodicon in the West Syrian Tradition*, ed. by A. Vööbus with English translation (1966).

**Philosophy.**—In philosophy, Sergius of Reshaina (d. 536) not only translated the works of Aristotle and Porphyry but also produced original works, the most important being on Aristotle's logic (Ms. Brit. Mus. Add. 14,658). Severus Sebokht (d. 667) wrote a dissertation on Aristotle's syllogisms (Ms. Brit. Mus. Add. 17,156) which has survived complete. Giwargis, bishop of the Arabs, cultivated peripatetic philosophy; his most important work is the commentary on the *Organon* and other works of Aristotle.

**Grammar.**—Grammatical studies, initiated by the translation of the Greek grammar of Dionysius Thrax (q.v.), were frequently treated. Among the West Syrians the work of Jacob of Edessa was an important stimulus; such writings culminated in the "Great Grammar" of Bar-Hebraeus. On the East Syrian side the studies of Hunain (d. 876) and others reached their climax in the work of John bar Zobi (13th century).

Bar-Hebraeus' "Great Grammar" was edited, with a German translation, by A. Moberg (1907–22).

**Science and Medicine.**—Encyclopaedias on the philosophical and natural sciences were written by Job of Edessa (9th century) and Jacob bar Shakkō (d. 1241). In astronomical knowledge a classical representative is the West Syrian Severus Sebokht. In medicine the Syrians drew their knowledge from the Greeks, hundreds of Greek medical works being translated by Sergius of Reshaina, whose reputation was equally great among all the Syrians; by Hunain, who also corrected earlier translations; and by other authors who were less prominent. To this, original works were added by Sergius of Reshaina, Simeon Taibuteh, and Hunain.

Job of Edessa's work was edited by A. Mingana with English translation, *Woodbrooke Scientific Publications*, vol. 1 (1935).

**BIBLIOGRAPHY.**—W. Wright, *A Short History of Syriac Literature* (1894); R. Duval, *La littérature syriaque* (1907); A. Baumstark, *Geschichte der syrischen Literatur* (1922); J. B. Chabot, *Littérature*

*syriaque* (1935); A. Baumstark, *Die syrische Literatur*, in *Handbuch der Orientalistik*, III, 2 (1954); I. Ortiz de Urbina, *Patrologia Syriaca* (1958). (Ar. V6.)

**SYRINX**, the Greek name for the musical instrument more commonly known as the panpipes (see PANPIPE). In medicine and anatomy "syrinx" refers to: (1) a tubelike structure; (2) a fistula; and (3) a kind of secondary larynx found in birds.

**SYROS** (SYRA; modern Greek SÍROS), a Greek island in the centre of the Cyclades (length about 10 mi., breadth 6 mi.). Area 34 sq.mi. (88 sq.km.); pop. (1961) 19,750. Its importance in the Bronze Age is attested by Early Cycladic remains. In ancient times it was remarkably fertile, but the destruction of its forests led to loss of soil by erosion and left it a brown and barren rock with scanty aromatic scrub, pastured by sheep and goats. The Turks took it from the Venetians in 1537. During the War of Greek Independence (1821–29) Syros remained neutral; several thousand refugees, mostly from Chios and Psará, settled there under French protection (though the island was nominally Turkish until 1832) and helped make it the commercial centre of the archipelago in the 19th century. It later declined with the rise of Piraeus and Patras.

Hermoupolis (Greek Ermoúpolis; also called SÍROS), the chief town (pop. [1961] 14,402), and capital of the *nomos* of the Cyclades, stands on a bay on the east coast. Old Syros (Áno SÍROS), on a conical hill behind the port town, was built by the Venetians in the 13th century and still houses a large Roman Catholic settlement, mostly of Italian descent. Hermoupolis itself was founded by the refugees in the 1820s. The town is still of considerable industrial (tanneries, weaving, and loukoumi) and mercantile importance.

**SYZRAN**, a town of Kuybyshevskaya (Kuibyshev) Oblast' of the Russian Soviet Federated Socialist Republic, U.S.S.R. stands on the right bank of the Volga at its confluence with the Syzran River and just below its great loop around the Zhiguli hills. Pop. (1959) 148,866. The town was founded in 1683 as a stronghold at the eastern end of the Syzran defensive line. It is a significant river port and a major centre of the western part of the Second Baku oil field, and oil shales are mined near the town. Oil refining, glassmaking, engineering (agricultural machinery and hydroturbines), timber working, leather working, and food processing are the main industries. It is an important rail junction, with lines to Kuibyshev, Saratov, Penza, Saransk, and Ul'yánovsk. (R. A. F.)

**SZCZECIN** (German STETTIN), a town of northwest Poland and an important Baltic port, stands on Stettin Bay near the mouth of the Oder, 41 mi. (66 km.) from the sea. It is the administrative centre of Szczecin województwo (province). Pop. (1939) 268,915, almost entirely German and Protestant; (1960) 268,900, almost entirely Polish and Roman Catholic; (1964 est.) 303,000. The great shift in the population's composition resulted from the Potsdam Agreement of Aug. 2, 1945, which restored the town to Poland and transferred all German inhabitants who had not already fled to Germany.

Szczecin arose on the left bank of the Oder, in a valley surrounded on three sides by hills. The Old Town, with its fine Renaissance castle, still forms its heart. When the city walls were demolished in 1874 a new district was established, radiating from Grunwald Square. The neighbouring villages and hills were gradually incorporated, and residential districts were then built there. The industrial districts occupied the northern sector, along the Oder. The valley, there 4.3 mi. (7 km.) wide, is cut by tributary streams and canals, along which the port installations have been erected. Szczecin is one of the most picturesque towns in Poland, with lakes and parks and green spaces occupying nearly one-fifth of its area. The town has been rebuilt since World War II, when two-thirds of its buildings were destroyed or damaged.

The development of the port began in 1826, when regular navigation was started on the Oder. In 1926–27 the waterway to Swinoujście (Swinemünde) was deepened. All port installations were demolished during World War II, and the canals were blocked by rolling stock and cranes; restoration was slow. The

port's turnover increased by the mid-1960s to more than 11,000,000 tons. It has the largest turnover of all Polish ports and is the main coaling port. The cargoes handled are mainly coal, coke, and iron ore. Szczecin port constitutes an organic whole with the outport at Swinoujscie, which is also an independent junction for international sea lines and a harbour for deep-sea fishing fleets. The situation of both at the mouth of the Oder has led to the development of transit traffic with the German Democratic Republic, Czechoslovakia, and Hungary. Further deepening of the waterway has allowed still larger vessels to reach Szczecin.

The most highly developed industry of Szczecin is the building of ships, fishing boats, and yachts. Food-processing, chemical, and metal industries are also developing. There are an academy of medicine, a college of engineering, and a college of agriculture. The town also has four theatres, an opera house, a concert hall, and two museums.

A settlement was formed on the site of the present town about 2,500 years ago. A Slav Pomeranian fortress was erected there in the 9th century A.D., and the place became an important trade centre on the water and land routes. At the end of the 10th century it was incorporated in the Polish state by Mieszko I. The name of the town comes from *sacacina* (bristle), and it was known to the Danes as Børstaborg ("brush castle"). In 1243 Szczecin received municipal autonomy from Duke Barnim I, and it remained the capital of the originally Slavonic dukedom of Western Pomerania or Pomorze (q.v.) until 1637, when it passed to Brandenburg. It joined the Hanseatic League (q.v.) in 1360, and this contributed to its germanization. It was seized by the Swedes in 1648 and passed to Prussia in 1720. It was returned to Poland in 1945.

SZCZECIN *województwo* lies on the Baltic Sea bordering the German Democratic Republic and has a coastline of 53 mi. (85 km.). Pop. (1964 census) 838,000. The province was incorporated in Poland after World War II. It covers the western area of the Pomeranian lakelands, with varying moraine formations and numerous lakes. A deep layer of glacial formations covers Tertiary rocks with brown coal and Mesozoic rocks. The soils are mainly sandy and gray. Good chernozem soils are found only in the southern area of the province. About 32% of the population is employed in agriculture. The main crops are grain (rye, wheat, barley, and oats), potatoes, and sugar beet. Cattle breeding has not developed well, despite the meadows and pastureland. About 27% of the region is forested, and the timber economy of the province is at a high level.

Szczecin *województwo* is one of the least industrialized in Poland. Szczecin itself employs about 60% of those who work in industry. After shipping and shipbuilding, the principal industries are agriculture and timber. Fishing from Swinoujscie, Dziwnow, and Wolin is an important part of the economy. The best-known of the resorts along the coast are Miedzyzdroje and Swinoujscie. The main towns, after Szczecin, are Stargard Szczeciński, Swinoujscie, Solenow, and Gryfice. (T. K. W.)

**SZÉCHENYI, ISTVÁN**, COUNT (1791-1860), Hungarian reformer and patriot whom his antagonist Lajos Kossuth called "the greatest of the Magyars." He was born in Vienna, capital of the Austrian Empire, on Sept. 21, 1791, of a Hungarian family with a tradition of national service. He served with distinction as a cavalry officer against the French in the Napoleonic Wars. When peace was concluded, he spent several years traveling and was deeply impressed by the economic development and political institutions of France and, still more, of England, which he contrasted with Hungary's backwardness. His first intervention in public affairs (1825) was to offer a year's income (60,000 florins) from his estates toward the foundation of a Hungarian National Academy of Sciences. Thereafter he launched a variety of projects: some were apparently rather frivolous, such as the promotion of horse racing and the foundation of an aristocratic club, the National Casino; others were of obvious utility, such as the introduction of a steamship service on the Danube.

Széchenyi put the case for far-reaching reforms in a series of books, including *Hitel* ("Credit," 1830), *Világ* ("Light," 1831), and *Stádium* (1833). His originality as a reformer lay in his

iconoclastic attitude toward his nation's prejudices. While his fellow nobles believed all virtue to lie in the defense of the Hungarian constitution against Vienna, he declared boldly that the root of Hungary's evils lay in the antiquated nature of that constitution and, still more, in the laziness and complacency of its defenders: Hungary must reform its institutions and itself. His heart's inspiration was a love of his country and his people, but he put the case for all his reforms on realistic economic arguments: the nobles' exemption from taxation made it impossible to finance the modernization of the country; the inalienability of their estates meant that they could not raise credit on them for improvements; the servile condition of the peasants resulted in inefficient agriculture. The real purpose of his horse racing was to improve the breed of horses; that of the National Casino was to enable its members to read and to exchange ideas. So, too, he proposed to pay off the cost of a permanent bridge between Buda and Pest by a toll payable by all users, noble or not.

The effect of Széchenyi's activities was genuinely revolutionary. The traditionalist nobles were scandalized beyond measure, yet in a few years Széchenyi, almost single-handed, set the tide moving toward reform. By 1841, however, he was already a back number. His loyalty to the Austrian connection and his doctrines of self-criticism and self-help were distasteful to the younger generation; he in return feared that their chauvinism would drive Hungary into a conflict with Austria that must end in disaster. In his presidential address to the academy (1842), he protested against the attempt to Magyarize the non-Magyars of Hungary and was rewarded with a storm of abuse. He tortured himself with self-reproach for having opened an abyss and led Hungary to its verge. He joined forces with the Conservatives, for whom he took charge of the regulation of the Tisza River and the lower Danube. His *Fragments of a Political Programme* (1847) was an envenomed attack, political and personal, on Kossuth (q.v.).

Széchenyi took office in Lajos Batthyány's Cabinet of 1848 (see HUNGARY: History) as minister of communications and public works, but when conflict with Vienna broke out, his reason gave way; he was removed to an asylum at Döbling, a suburb of Vienna (Sept. 5). Even so, in 1859 he could publish a barbed polemic against Austrian absolutism in Hungary. Threatened with prosecution for sedition, he took his own life on April 8, 1860. Collected editions of his works appeared in 1884-96 and in 1922-30. See A. Zichy, *Gróf Széchenyi István*, 2 vol. (1896-97). (C. A. M.)

**SZECHWAN** (SSU-CH'UAN SHENG), a province of southwest China, almost 220,000 sq.mi. (569,000 sq.km.) in area following the reaccession of Sikang (q.v.) in 1955. Pop. (1953) 65,685,063 (including Sikang); (1957 est.) 72,160,000. It contains four autonomous areas formed since 1952, inhabited predominantly by non-Han peoples (under 2% of total provincial population) living in the mountainous west and southwest: Ahpa (A-pa), Kantzu and Mu-li—all mainly Tibetan; and the Liang-shan area. Szechwan was once almost a separate country because of its size and population, as well as its self-sufficiency in resources.

**Geography.**—Topographically it is distinctive, with lofty mountains everywhere and tremendous rivers of unmeasured power potential. From cloud-ringed O-mei Shan, 9,900 ft. (3,020 m.) (famed for temples, monkeys and pines), southwest of Ch'eng-tu, to the infinite complexity of irrigated garden-patch farms, and the inspiring 1,000-2,000 ft. (300-600 m.) gorges of the Yangtze (q.v.), the marks of man's adjustment and transformation of the landscape are everywhere. The heart of the province is the Szechwan or Red basin that occupies a region that continued as a sea gulf well into the later Paleozoic period, and changed to a fresh-water lake during the Mesozoic with deposition of red sandstones and limestones that were later wrinkled into a northeast-southwest ridge and valley system. On the west are the young Great Snow mountains (Tahsüeh Shan) and the eastern plateau of Tibet, 13,000 ft. (4,000 m.) above sea level; to the north, the Tsingling Shan at 10,000 ft. runs into the Ta-pa Shan and Wu Shan on the east, while the south is marked by the Kweichow limestone plateau. The largest flat area is the Ch'eng-tu plain in the northwest of the basin. Szechwan means "four streams"; they are usually regarded as the Min, T'o, Chia-ling and the Ch'ien or Wu;

sometimes either the Yangtze or Fou Chiang is given instead of the Ch'ien. Most of the major streams flow south, cutting steep gorges through former Sikang, or widening their valley floors in the soft sediments of the Red basin to pour eventually into the Yangtze before it slices its precipitous gorge, 150 mi. due east, through the Wu Shan below Wan-hsien. Within the basin most of the rivers are navigable and provide the most common means of transportation. Inside the mountain ring, which provides a barrier against polar winds, a mild climate permits the growth of almost every crop and tree found in China. Precipitation averages 40 in. (1,000 mm.), and the growing season is 11 months; snow and freezing are rare although the foggy winters are penetrating. Because of the high humidity and constant cloud cover, the Chinese say that in Szechwan the dogs bark when they see the sun.

**Agriculture.**—Given favourable conditions for agriculture the large population has converted lowlands and terraced hillsides into intensive gardens everywhere. Rice, sweet potatoes, sugar cane, silk, tea, citrus, tobacco, cotton and tung oil are the primary products, with wheat, corn, soy beans, white potatoes and barley as secondary. Bamboo and palms on the lowlands are matched by conifers and alpine meadows on the high mountains. Szechwan is China's largest rice producer with surpluses for transport to deficit areas, along with outshipments of sugar, citrus, tung oil, spices and medicinal products. Liang-shan writing paper made from bamboo is prized by Chinese artists. The world's best natural bristle is plucked from the backs of Szechwan hogs; goats are also reared. Within high, secluded bamboo glades in the west live the rare giant panda bears.

**Industry.**—Minerals of industrial importance are increasingly exploited. Salt has long been pumped from natural brine wells, from 300 to more than 1,000 ft. deep, at Tze Kung, while bituminous coal outcrops are numerous around Chungking (*q.v.*). Iron ores are scattered; the largest deposit, estimated at 500,000,000 tons of about 40% iron content, is in the southeast of former Sikang province. Petroleum is reported extracted and refined on the middle Chia-ling river, less than 90 mi. N. of Chungking, while in the salt well area natural gas is also being converted into petroleum. Szechwan's first major hydroelectric station (48,000 kw.) was built northeast of Chungking. From the mountains in the west, small amounts of gold, silver, copper, lead, antimony and asbestos are produced. The pace of industrialization continues to increase. Chungking, the major industrial centre of southwest China, has an automatic thermoelectric power plant, iron and steel plants (open hearth and electric), textile mills, chemical works and lighter industries. Electric trolley buses run in the widened downtown streets, while cable cars have replaced many of the long flights of stone steps down to the rivers. In 1952 Szechwan's first railway, 313 mi., between Chungking and Ch'eng-tu, the provincial capital, was opened, followed in 1958 by the Pao-chi to Ch'eng-tu line, 400 mi. across the Tsinling Shan to the north. Two more lines are growing south, one from Chungking to Kuei-yang in Kweichow (190 mi.), by a bridge across the Yangtze; the other from Nei-chiang, the sugar centre, to K'un-ming in Yunnan (420 mi.). Ch'eng-tu is the terminus of the motor roads to the west. That change will continue is obvious, for there remains the challenge of damming the lower end of the great Yangtze gorges, a project first drafted during World War II and taken up again in China in the late 1950s; this would be one of the world's largest multipurpose river control projects, with 10,000,000 kw. power available for a 300-mi. area.

**History.**—In the past the keynote of Szechwan was isolation. Non-Han peoples related to the Thai stocks had their centres of the Shu and Pa states at Ch'eng-tu and Chungking respectively at least as early as the Chinese settlement in the Yellow river valley. They were conquered by the Ch'in from the north in 316 B.C., augmented by a large number of transported Chinese settlers who enlarged Ch'eng-tu's great irrigation system and built the walled city. A possible remnant of the pre-Chinese exists southwest of the Min Chiang in the Liang-shan autonomous area formed in 1952. During the Three Kingdoms period (A.D. 221–265), Ch'eng-tu formed part of the base of Chu-ko Liang, one of China's shrewdest and most admired historical strategists. At

the end of the Ming dynasty widespread massacres left vacant land that was occupied in the 18th century by whole outside communities—most notably a large contingent from Kwangtung whose descendants around Ch'eng-tu still speak Cantonese. Since the main routes into Szechwan were over the Tsinling Shan, with the shift of Chinese power east and then south the province was somewhat forgotten except as a rice granary and control base against the non-Hans to the west. During the warlord days of the republic, the area was practically impregnable. After the start of the Chinese-Japanese war in 1937, industrial enterprises and millions of refugees from coastal provinces were evacuated to Szechwan which resulted in rapid economic development of the area. Chungking, former treaty port and the wartime capital of China, made Szechwan the political and economic centre and became the site of important military bases and headquarters installations for Chinese and allied forces.

Although the Japanese bombing of Szechwan cities, especially Chungking, was severe, the province was not entered by the invaders. However, in spite of other large cities like Ch'eng-tu, Luchow, Wan-hsien and I-pin (*qq.v.*), most of the population remains basically rural. (T. H.)

**SZEGED**, a city in Hungary with *megye* (county) rights, lies just below the confluence of the Maros and Tisza rivers, geographically within Csongrád *megye*, 118 mi. (190 km.) SE of Budapest by rail. Pop. (1960) 99,061. A stronghold and trading entrepôt in the time of the Árpád kings (c. 890–1301), Szeged was sacked by the Tatars and Turks. The oldest building is the 16th-century Mátyás (Mathias) Church in the lower town (Alsóváros). The town developed in the 19th century as an important rail and road intersection point and river port, trading in Transylvanian timber, rock salt, and local farm produce. It became the economic centre of the Banat (a fertile region producing grain, paprika, tobacco, and hides) but lost this position after 1920 when most of the Banat was ceded to Rumania and Yugoslavia. Its university, founded in 1921, was originally a branch of the university at Cluj (Kolozsvár) in Rumania; there is a separate medical university. After World War II the textile industries were vigorously developed.

The town was rebuilt after the disastrous spring floods of 1879 with an encircling protective dike and two concentric arcs of boulevards. Apart from a conventional 19th-century town centre and the developing industrial quarters, a steppe village-town plan predominates, comprising low-built houses (with attached farmyards) that border wide streets. These sprawl out to the dike and beyond into the Great Alföld (plain), forming an extensive suburban area that was once part of the city but incorporated into Csongrád *megye* in 1950. (H. G. S.)

**SZÉKESFEHÉRVÁR** (German *STUHLWEISSENBURG*), the capital of Fejér *megye* (county) in west-central Hungary, lies 41 mi. (66 km.) SW of Budapest by rail. Pop. (1960) 55,934. The site of a Roman settlement, Alba Regia, it was chosen by Stephen I in the 10th century as capital of the early Hungarian kingdom which it remained for 500 years. It became a strong fortress with a natural defense of marsh surround. In 1543 it was occupied by the Turks who sacked it before their withdrawal in 1686. The later 18th-century town was built largely from the ruins of the old one and contains a Baroque episcopal church and an episcopal palace in Empire style. Székesfehérvár was badly damaged (1944–45) during the fighting between German and Soviet troops. The town's traditional economic importance is as a market centre for local truck farmers, vine growers, and horse breeders, but it now has some light industries. Since the 19th century it has been a road and rail junction on the main routes from Budapest to the southwest. (H. G. S.)

**SZEKLERS** (Magyar *SZÉKELY*), a people inhabiting the upper valleys of the Mureş and Olt rivers in what was eastern Transylvania and is now Rumania. They were estimated to number very roughly about 400,000 in the 1960s and are officially recognized as a distinct minority group by the Rumanian government. Their origin has been much debated. According to their own tradition, repeated in Procopius' *De bello Gothico*, they were descended from Attila's Huns, while others have seen in them Black

Ugrians. It is, however, now generally accepted that they are true Magyars (or at least the descendants of a magyarized Turki people) transplanted there to guard the frontier, their name meaning simply "frontier guards."

Their ethnic identity as distinguished from other Rumanians is largely preserved by the continuing vitality of the Szekler (Szekel) language, a Magyar dialect (see HUNGARIAN LANGUAGE). Runes of ancient Turkic origin continue to be used as a written alphabet, the latinized Rumanian script being largely used for official and commercial communication, however. By the terms of the 1952 Rumanian constitution, the province of Mureș (with the highest concentration of Szekler population) was legally designated as the Magyar Autonomous Region (1964 pop. 819,429).

See also RUMANIA: *The People*.

**SZENT-GYÖRGYI, ALBERT** (1893– ), Hungarian-U.S. biochemist, who was awarded the 1937 Nobel Prize for medicine and physiology "for his discoveries in connection with the biological combustion processes, with especial reference to vitamin C and the catalysis of fumaric acid," was born in Budapest on Sept. 16, 1893. His medical education at Budapest was interrupted by World War I, but he used an interval of leave after being wounded to complete his studies and graduate M.D. (1917). After the war he held posts at Pozsony (later Bratislava), Prague, Berlin, Hamburg, Leiden, and Groningen. In 1927 he transferred his laboratory to Cambridge, Eng., and subsequently spent a year in the United States. He returned to Hungary in 1932 and held the chairs of medical chemistry at Szeged and at Budapest. In 1947 he emigrated to the United States and became director of the Institute for Muscle Research at the Marine Biological Laboratory at Woods Hole, Mass. He became a citizen of the United States in 1955.

Szent-Györgyi's greatest achievement was the isolation from the adrenal glands and from various plant juices of hexuronic acid (ascorbic acid) and the provision of definite proof that this substance is identical with vitamin C. He was also the first to demonstrate the presence of flavin (riboflavin, or vitamin B<sub>2</sub>) in animal tissues. With S. Ruznyak and others he investigated a substance, which he called vitamin P, that prevents abnormal capillary permeability in scurvy.

**SZOLD, HENRIETTA** (1860–1945), founder of what became through her leadership the world's largest Zionist group, Hadassah (q.v.), the Women's Zionist Organization of America, was born in Baltimore, Md., Dec. 21, 1860. She pioneered in Americanization work after 1882, originating (1891) the night school for immigrant workers in Baltimore. A founder of the Jewish Publication Society of America (1888), she served until 1916 as the society's editor general, translator of Jewish classics and writer. In 1912, with 12 members, Miss Szold founded Hadassah. As its president she organized in 1916 a medical unit for Palestine comprising staff and equipment for hospitals, nurses' school, clinics and epidemiological and teaching services. The first woman elected to the World Zionist executive and member of the Palestine Jewish National Council, she held their portfolios of health, education and social welfare. She established Lema'an Hayeled (named after her death the Szold Foundation) for child welfare and research in juvenile problems. In 1933 she became director of Youth Aliyah, a worldwide movement to rescue and rehabilitate in Israel young victims of Nazi and other persecution. She worked also for Arab-Jewish *rapprochement* through common so-

cial and political planning. Miss Szold died in Jerusalem Feb. 13, 1945. She was recognized as the outstanding Jewish woman of her time, a pioneer in international social service, education and Zionist thinking.

See Marvin Lowenthal, *Henrietta Szold: Life and Letters* (1942); Rose Zeitlin, *Henrietta Szold* (1952). (T. DE S. P.)

**SZOLNOK**, a town of central Hungary and capital of Szolnok megye (county), lies 57 mi. (92 km.) ESE of Budapest at the confluence of the Tisza and Zagyva rivers. Pop. (1960) 45,553. Under the Árpád kings (c. 890–1301) it became a market and distributing centre for the rock salt of the Maramureș Basin. In the Middle Ages it was a noted strongpoint, fiercely contested by Magyars and Turks. In modern times it developed as a road and rail junction. The main road from Budapest to Debrecen passes through it, and railways with connections to Rumania, Yugoslavia, and the U.S.S.R. converge to cross the great bridge over the Tisza, completed after World War II. The town's activity is concerned mainly with the transit of goods rather than with industrial production, although several modern factories have sprung up on the right bank of the Tisza. One of Szolnok's assets is the subterranean supply of medicinal waters pumped from artesian wells, at a depth of more than 3,000 ft. (900 m.), to baths near the Tisza bridge. (H. G. S.)

**SZOMBATHELY** (German STEINAMANGER), the capital of Vas megye (county), Hung., lies near the Austrian-Hungarian frontier on the Gyöngyös River, a tributary of the Rába (Raab), 162 mi. (261 km.) W of Budapest. Pop. (1960) 54,465. The town is the successor of the nearby Roman settlement of Savaria (Sabaria), the capital of Pannonia (q.v.), and it was there in 193 that Septimius Severus was proclaimed emperor by his legions. St. Martin, bishop of Tours, was born there c. 330. The town was sacked by the Huns in the 5th century and declined in medieval times. In the 18th century Maria Theresa of Austria chose the city for the seat of a bishopric. The episcopal palace (Püspökvár) and the fine Baroque cathedral were built between 1781 and 1813. Szombathely grew in importance as a railway junction for the trunk lines from Vienna, Graz, Budapest, and Zagreb and developed as an agricultural centre, especially for local wines, fruit, honey, and spices, and for the manufacture of agricultural machinery. (H. G. S.)

**SZYMANOWSKI, KAROL MACIEJ** (1882–1937), Polish composer of orchestral music and the leading figure in the Polish musical revival, was born on Oct. 6 (new style; Sept. 24, old style), 1882, at Timoshevka, near Elisavetgrad in the Ukraine. He studied with his father and Gustav Heukas and in 1901 with Z. Noskowski in Warsaw. His early piano works include preludes, studies, and the variations, op. 3. Though influenced by Scriabin and Richard Strauss, his style developed between 1909 and 1913 in his second symphony, second piano sonata, and the opera *Hagith* (Warsaw, 1922). During World War I he wrote his third symphony, showing oriental affinities; *Métopes* for piano; the *Mythes* for violin, including *The Fountain of Arethusa*; and the first violin concerto. Szymanowski's later works were remarkable for their lyrical inspiration and ornate craftsmanship. The best of his songs were written from 1915 onward and include the cycle *Słowieńce*. His style reached maturity in the opera *Król Roger*, containing the well-known "Song of Roxana" (Warsaw, 1926). Folk-song elements were used in his ballet *Harnasie*. In his *Stabat Mater* and *Litania* he revived an archaic style. In 1926 he became director of the Warsaw Conservatory. His last compositions include the *Symphonie Concertante* and the second violin concerto. He died at Lausanne, Switz., on March 29, 1937.

See Stefania Lobaczewska, *Karol Szymanowski* (1950).

THIS letter corresponds to Semitic *tau* (meaning “mark”), the form of which on the Moabite stone (see MOAB) was **X**. In all Greek alphabets, as well as in the Lydian and the Latin, the form was **T**. Etruscan had a form **†** from which probably were derived the Umbrian form **†** and the Faliscan **†** and **‡**.

Latin cursive gives a form that leans to the right **T**. Carolingian **T** is based upon uncial **T**. Generally speaking, in medieval manuscripts the minuscule letter did not rise above the line and is sometimes difficult to distinguish from a minuscule *c*. In modern handwriting and printing, it is the custom to extend the vertical stroke above the horizontal.

The sound represented by the letter throughout its history has been the unvoiced dental stop. In English this has become more alveolar than dental, that is to say, it is pronounced by the tongue pressing upon the gums rather than the teeth. English unvoiced stops are probably also to be distinguished from the corresponding sounds in ancient Greek by the addition of a slight puff of breath following the sound, thus bringing the sound near

to being an aspirate. Greek would perhaps have transliterated the English unvoiced stops by the letters  $\theta$ ,  $\phi$ , and  $\chi$  rather than  $\tau$ ,  $\pi$ , and  $\kappa$ . This tendency toward aspiration is carried to much farther lengths in the Irish dialects of English.

For an account of the Germanic consonant shifts involving the letter T, according to Grimm’s Law, see GERMANIC LANGUAGES. See further ALPHABET. (B. F. C. A.; J. W. P.)

**TAAFFE, EDUARD, GRAF VON** (1833–1895), Austrian statesman whose tenure of office lasted longer than that of any other prime minister of the emperor Francis Joseph (*q.v.*). He was born in Vienna on Feb. 24, 1833, into a noble family of Irish origin. Brought up with Francis Joseph, he entered the public service in 1852 and was governor of Upper Austria in 1867. After being minister of the interior under F. F. von Beust (*q.v.*), he became minister of defense and public security on Dec. 30, 1867, in

the “bourgeois ministry” of Prince Carlos Auersperg, whom he succeeded as prime minister of Austria on Sept. 24, 1868. Advocating concessions to the Czechs, against the majority of his colleagues, he resigned on Jan. 15, 1870, but was recalled to be minister of the interior under Alfred Potocki in April. When that cabinet fell (Feb. 4, 1871), he was appointed governor of Tyrol.

Taafe became minister of the interior again on Feb. 15, 1879, under Karl von Stremayr, and succeeded him as prime minister on Aug. 12. Professing himself devoted solely to his emperor, he relied mainly on the support of the Catholic Church and of the Slavs of the Austrian lands (Czechs and Poles) against the German nationalists (Liberals and others). His adroit opportunism, with the successes of his foreign minister G. S. Kalnóky (*q.v.*), recovered much of the prestige that Austria had lost since the 1850s (see AUSTRIA, EMPIRE OF), notwithstanding the scandal of the suicide of the crown prince Rudolf (*q.v.*) in 1889. His concessions to the Czechs, however, failed to satisfy the Young Czech Party (see BOHEMIA), and finally he tried to conciliate the Social Democrats with a bill for universal suffrage. When this was rejected by the *Reichsrat*, he resigned (Nov. 11, 1893). He died at Ellischau (Nalžový), in Bohemia, on Nov. 29, 1895.

**TABARI, AL- (ABU JA’FAR MOHAMMED IBN JARIR AL-TABARI)** (c. 838–923), Arab historian and theologian, was the author of a history of the world generally known as the *Annals*. Born at Amol in Tabaristan, he studied in Baghdad, Syria, and Egypt. Most of the rest of his life he spent in Baghdad, first as tutor to the vizier’s son, then as a teacher of law and Tradition.

Originally a follower of the Shaf’ite school of law, he later established a school of his own; its influence was, however, short-lived. The *Annals* (*Tarikh al-Rusul wa-al Mulk*, “History of the Prophets and Kings”) are a general history from the Creation to A.D. 915 and are famous for their detail and, in the later parts, their accuracy (see ARABIC LITERATURE: *History and Biography*). His second great work, a commentary on the Koran (*Jami’ al-Bayan* or *Tafsir*), is marked by the same fullness of detail.

**BIBLIOGRAPHY.**—The *Annals* were ed. by M. J. de Goeje, 13 vol. (1879–1901). The commentary on the Koran was published in 10 vol. (1905–12), ed. by M. M. Shakir and A. M. Shakir, 3 vol. (1954–). See also D. S. Margoliouth, *Lectures on Arabic Historians* (1930).

**TABASCO**, a Gulf Coast state of southeast Mexico. Area 9,522 sq.mi. (24,661 sq.km.). Pop. (1960) 496,340. The surface is generally low and flat, largely covered with lagoons, water-courses, and swamps. In the south and southeast there is a higher area. Tabasco, a region of very heavy rainfall, is covered by dense forests that provide valuable fine woods and dyewoods. It is traversed by two large rivers, the Grijalva and Usumacinta. The Grijalva, also called Tabasco, is navigable for 62 mi. (100 km.). The Usumacinta forms the boundary between Guatemala and Chiapas until the frontier of Tabasco is reached; it eventually flows into the Grijalva, the two rivers having a common outlet. The Usumacinta, including its headstreams, is about 500 mi. (800 km.) long; it is navigable for about 310 mi. but only about 180 mi. by large steamers. There are few good roads, and the rivers are the principal means of transportation in the state. There are also air and rail lines. The state capital is Villahermosa. The next most important town is Frontera, a port 3 mi. within the mouth of the Grijalva.

Juan de Grijalva explored the area in 1518, and in 1519 Cortés first clashed with the Indians, from whom he acquired his faithful ally, Malinche. Francisco de Montejo partially subdued them after constant uprisings in the 1530s and 1540s. Tabasco, an Indian name meaning “damp earth,” became a state in 1824. The potential oil wealth of the area began to be exploited in the 1950s. Cattle, copra, bananas, cocoa, coffee, rice, sugarcane, rubber, vanilla, tropical fruits, and corn are the main agricultural products.

VILLAHERMOSA lies on the Grijalva River in an area of heavy rainfall. Pop. (1960) 52,262. It serves as a market centre for

the cattle ranches and banana plantations of the surrounding countryside. In the mid-20th century Villahermosa became an important airline terminal.

**TABERNACLE** (Hebrew *mishkān*, literally "dwelling"), the name given in the English Bible to the portable sanctuary said to have been constructed by Moses in the wilderness as a place of worship for the Hebrew tribes (Ex. 25-31, 35-40). It is commonly held by scholars that this elaborate building, together with the complex ceremonies connected with it, is largely the product of a theoretical attempt to read back into the wilderness period the architecture and ceremonies of the later Jerusalem Temple.

The historical nucleus of this idealized structure is found in the ancient tradition that Israel's earliest sanctuary, before the building of a permanent Temple, was a simple tent—set up outside the tribal camp—within which God manifested his presence and communicated his will ("the tent of meeting," Ex. 33:7-11). The present biblical account of the building of the tabernacle is of exilic or postexilic date and is contained in the "Priestly" document of the Pentateuch (see **PENTATEUCH**), which reflects the theology of the Jerusalem priesthood. For them it was of transcendent importance that God should have a habitation where he might "dwell" among his people (Ex. 25:8; cf. I Kings 8:12 ff.; Ezek. 37:27). Characteristically, the Priestly writers transfer the portable sanctuary from outside the camp to its centre. As with the Solomonic Temple, the entire complex consisted of a large court surrounding a comparatively small building (the tabernacle proper). The court, to which alone the congregation

was admitted, was enclosed by linen hangings and had the form of a rectangle composed of two squares. In the centre of the eastern square stood the altar of sacrifice (burnt offering), with a laver (a copper-bronze basin holding the water with which the priests performed their ritual ablutions) nearby; the corresponding position in the western square was occupied by the ark (*q.v.*), situated in the inner sanctuary of the tabernacle.

The tabernacle itself was constructed of tapestry curtains, decorated with cherubim, spread over a framework of wood covered with gold. These delicate tapestries were protected by successive coverings of goat's hair cloth, tanned rams' skins, and goatskins. The entrance, at the east end, was closed by a "screen" (or portiere) hung from five pillars; the interior was divided into two rooms—"the holy place" and "the most holy place" ("holy of holies")—by a veil of the same material as the curtains of the walls and ceiling, hung on four pillars. The outer of these rooms (the holy place) contained the table on which the bread of the Presence (the shewbread) was placed, the altar of incense, and the seven-branched lampstand. The inner room (the most holy place), which was a perfect cube having just half the floor area of the outer, was conceived to be the actual dwelling place of the God of Israel, who sat invisibly enthroned above a solid slab of gold (the propitiatory or mercy seat) that lay upon the ark, a gold-covered wooden box containing "the testimony" (*i.e.*, the tablets of the Decalogue). At either end of the golden slab rose the golden figures of the cherubim. See also **TEMPLE, JEWISH**.

**TABES DORSALIS (LOCOMOTOR ATAXIA)** is a form of neurosyphilis characterized by chronic degeneration in the posterior columns of the spinal cord. The disease results in loss of muscular coordination. The first symptom, which occurs between about 15 and 25 years after infection, usually is a lessening or the loss of the ankle and knee reflex. As the disease progresses, the patient gradually loses his ability to walk and stand normally. Treatment is the same as for other forms of late syphilis. See also **VENEREAL DISEASES: Syphilis; Neurosyphilis**.

**TABLE**, a fundamental piece of furniture, in its simplest form is a flat slab supported on legs or pillars. From very early times the table was used for eating; in more advanced civilizations a great variety of designs were devised for other uses.

## EARLY TYPES

The table was known in a small and rudimentary form to the Egyptians, who used wood for its construction. The Assyrians had tables of metal and possibly other materials. Grecian tables were of bronze supported on three or four legs; in Roman villas the most favoured form was the tripod, but tables were also made with a single pillar or with four legs. The more costly examples were carved, inlaid, or otherwise ornamented. Cedar and other woods with a decorative figure were used in their construction. The legs, usually of bronze, were cast in the form of animals, sphinxes, or grotesque figures; examples found at Pompeii and Herculaneum are of graceful design and delicate workmanship. Most of the Greek and Roman tables were made for the use of persons who reclined on couches while eating and, therefore, were considerably lower than modern Western dining tables.

In early medieval times all furniture was very primitive, but some faint memory of the refinements of classical Roman civilization must have survived. Thus the emperor Charlemagne (d. 814) possessed three tables of silver and one of gold. (These were doubtless of wood covered with thin sheets of precious metal.) In the later Middle Ages long tables with rectangular tops were used in the great hall where the entire household assembled for meals, while smaller tables with circular or rectangular tops were set in the private chamber of the master of the house. In the hall the high table for the master and his guests stood on a dais, sometimes surmounted by a canopy, while at right angles to it down the length of the hall side tables were placed for the remainder of the company. Some medieval illuminated manuscripts show state banquets taking place at round tables with the guests seated on curved benches; a 15th-century example survives in Winchester Castle (Hampshire). The characteristic medieval table, consisting of massive boards of oak or elm resting upon trestles, could be dismantled and removed after meals.

Tables with attached legs, joined by heavy stretchers fixed close to the floor, appeared in the 15th century and became standard in the following century. These tables could not be dismantled and were not easily removable. In the early 16th century there was introduced an ingenious form of joined table, known as a "draw" table, which allowed for easy extension to double its normal length. The top was composed of three leaves, two of which were placed beneath the third. The two under leaves, supported on runners, could be drawn out, and when they were fully withdrawn the upper leaf fell into place between them. Such tables were commonly of oak, but walnut, elm, cherry, and other woods were also used. They remained in general use until well into the 18th century. The typical Elizabethan draw table was supported on four vase-shaped legs terminating in Ionic capitals at the top. In the 17th century the vases were often of vastly exaggerated proportions but became more modest as the century progressed. The illustrated inventory of the 25 tables of "Walnuttree and Markatre" and 14 of marble owned by Lord Lumley in 1590 shows a cosmopolitan taste; many are of Italianate style, with inlaid marble tops on a single baluster support. In Italy the Florentine artists in *pietra dura* (or coloured marbles) produced costly table tops overlaid with intarsia of semiprecious stones, which were exported widely.

## LATER TYPES

**The Folding Table.**—The most important innovation of the 17th century was the gate leg table, the distinctive feature of which was a top with one or more flaps supported on pivoted legs, each pair being joined at top and bottom by stretchers and so constituting a gate. Tables with folding tops were known in the 16th century, but their use did not become general until the 17th. The earlier examples had as a rule a single flap, but a triangular type with three flaps is known. By the mid-17th century two flaps were usually provided, producing an oval table large enough for dining, which took up very little space when the flaps were lowered and the gates folded into the frame. This construction has remained in use until the present day.

The smaller flap table with a single pivoting leg remained very popular in England throughout the 18th century, particularly for card tables. These were constructed in walnut, mahogany, or satinwood and when not in use were set against the walls as side tables. Excellent carving was lavished on the cabriole legs of these tables; on the finer examples the knees were carved with a shell or mask, and the feet ended in a claw and ball or a sensitively modeled volute. The folding table did not enjoy the same popularity in continental Europe as in England. Its appearance there—mostly in the west—was due to English influence, and its form varied little from the English prototype.

**The Side Table.**—A side table or serving table came to be an indispensable feature of the dining room, and in some instances it was fitted with shelves upon which the gilt plate of the house was displayed. The 18th-century side table was often intricately carved, either in gilded softwood or mahogany, and usually had a marble top. The weight of the marble necessitated a robust construction, but the elegance of the design with cabriole legs, carved frieze, and mask pendants gave an impression of lightness. Toward the end of the 18th century furniture makers began to pay more attention to convenience than to magnificence of effect, and the side table (which when used as a dining room serving table had provided no accommodation apart from its upper surface) developed into the true sideboard (see *CABINET FURNITURE: Neoclassicism*).

**The Console Table.**—This term is used to describe a type of table supported on brackets like consoles, or on two legs of similar form; it was designed to be placed against a wall and the back was usually screwed to the wall. The form originated in France or Italy in the latter part of the 17th century but soon became universal in noblemen's houses throughout Europe. The frames were elaborately carved and gilded, and the tops were made of coloured marble, or even semiprecious stones. Console tables were usually made in pairs or sets of four designed to stand between windows or on each side of doors and often had mirrors *en suite*. Their makers tended to borrow their designs from printed pattern books, and this has resulted in some uniformity of design, even in places geographically remote.

**The Silver Table.**—During the second half of the 17th century there appeared side or toilet tables with wooden frames completely covered with plaques of embossed and chased silver; such tables usually formed part of a suite consisting of table, looking glass, and a pair of candlestands. A number of late 17th-century examples survive in England (e.g., in Windsor Castle), while some of the German palaces (Dresden or Hanover) have 18th-century suites of silver furniture. In England the silver table was replaced in the early 18th century by tables of similar design covered with gilt gesso, which was much less costly.

The term "silver table" is also applied to a light four-legged table of wood with a gallery around the edge. It was used to support the tea or coffee service, which might be of silver or of porcelain; the gallery prevented pieces from being knocked off.

**Writing and Toilet Tables.**—In the 18th century both English and French cabinetmakers showed great ingenuity in designing writing and toilet tables with numerous mechanical devices that could be folded into a small space. The pattern books of Thomas Sheraton (*q.v.*) show many such devices; the cabinetmaker David Roentgen, who worked in Germany and France, achieved fame throughout Europe as a constructor of toilet tables of this type.

**The Wine Table.**—Another invention of the latter years of the 18th century was the wine table, which was narrow and of semi-circular or horseshoe form; the guests sat around the outer circumference. In the more elaborate versions the tables were fitted with a revolving wine carriage or bottle holder.

**The Gueridon.**—This is a small table designed to support a lamp or candelabrum. It originated in France toward the middle of the 17th century. Later examples, produced in Venice in the 18th and 19th centuries, were often supported by exotic figures.

**Other.**—The mahogany table with extra flaps, which could be inserted and supported on hinged legs to meet the varying needs of the company, had appeared in England in the 18th century and continued in vogue, with increasing heaviness, throughout the Victorian era. The elaborately carved and inlaid legs of the Victorian table were usually hidden beneath a voluminous tablecloth, but outstanding makers, such as Gillow or Holland, produced original designs that were carried out by craftsmen of unequalled skill. Apart from the low coffee table, no essentially new table forms have been devised in the 20th century. The architectural features of the table have, however, attracted architect-designers, such as Alvar Aalto. Space problems in modern apartments have encouraged experiments in convertibility. Such experiments as these have included adjustability of height, so that the dining table when not in use as such could be lowered to become a coffee or decorative table.

## THE ORIENT

Tables have occupied a far less important place in the Orient. In both Near and Far East the custom of sitting on the ground when eating has resulted either in very low tables or in no table at all for this purpose, and it is only in China, where chairs were adopted, that there has been any development analogous to that of the West. Large tables were never in favour, however, and large gatherings would sit at multiple tables; these were often round, the dishes being placed in the centre, and the radius conditioned by the length of the human arm. In both Near and Far East low tables were used for writing, and Indian miniature paintings show small tables placed by the side of couches for drinking vessels or smoking equipment. From the 18th century there has been a large production of small decorative tables in China, Japan, and the East Indies for export.

See *FURNITURE DESIGN* for illustrations and bibliography.

(J. F. H.)

**TABLE MOUNTAIN** (TAFELBERG) is the conspicuous flat-topped mountain lying to the south of Cape Town, South Africa, and towering above the city. The mountain forms the northern end of the high and rocky Cape Peninsula, which is composed of granite, Malmesbury shales, and, uppermost, the beds of the Table Mountain Series (Cape System), of which the Table Mountain Sandstone is the hardest and thickest rock. It is this sandstone lying almost horizontal, which gives the mountain its characteristic tabular form, vigorous water and wind erosion having formed the precipitous two-mile-long northern face. The surface of the mountain is a plateau about 3,500 ft. (1,065 m.) high, backed by a lower plateau deeply dissected in places by stream erosion. The highest point (3,567 ft. [1,087 m.]) is Maclear's Beacon (near the northeastern face), set up by Sir Thomas Maclear in 1865. Detached from the main mountain by erosion are two subsidiary peaks: to the northeast the Devil's Peak (3,270 ft. [997 m.]) formerly called Windberg or Windy Mountain; and to the northwest Lion's Head (2,178 ft. [664 m.]), the lion's "back" declining northward to Signal Hill (often called the Lion's Rump).

The mountain is sometimes covered by the so-called "tablecloth," a more or less thick cloud, produced most often by southeasterly winds, the cloud or fog soaking the mountain top and the eastern slopes. Most of the annual rainfall is brought by the northwesterly winds in winter, the amounts varying between about 60 in. (1,525 mm.) at the top and 22 in. (560 mm.) in parts of Cape Town at the foot of the mountain. Five reservoirs on the mountain contribute to the water supply of Cape Town.

The flora of the mountain includes many proteas, heaths, and the very beautiful disa orchids which flourish in the very moist

areas. The Compositae or daisy family of the Cape Peninsula number more than 60 native genera and 250 species, many of these being found on the mountain. On the drier western side of the mountain, succulents occur, including a few euphorbias and the stapelia or "carrion flower." Trees include the characteristic silver tree, together with the stinkwood, yellowwood, ironwood, and other trees also found in the Knysna Forest.

There are more than 300 classified routes up the mountain, varying greatly in difficulty. Access to the top was provided in 1929 by an aerial cableway, which transports 50,000 passengers annually to the summit.

See C. A. Lückhoff, *Table Mountain* (1951).

(J. H. Wn.)

**TABLE TENNIS**, an extremely fast indoor game, similar in principle to lawn tennis, was apparently derived from real or royal (indoor) tennis about 1880. It was known also under various trademarks ("Gossima," "Ping-Pong," etc.); in 1926 the present name was adopted by the International Table Tennis Federation (ITTF). Table tennis is a popular tournament sport in the Orient and Europe. There is limited interest in tournament competition in the United States, but it is a popular participant sport; tables and equipment are widely available at schools and public recreational facilities and in many private clubs and recreation rooms.

The ITTF, founded in Germany in January 1926, called a meeting that was attended by representatives of Austria, England, Germany, Hungary, and later that season of Czechoslovakia and Sweden. Thirteen congresses were held between the years 1926–27 and 1938–39 in European cities and in Cairo, Egypt. Suspended during World War II, it held its first postwar congress in Paris in March 1947. Congresses were later held (1948–57) in Europe, India, and Japan. The World Congress of 1957 was held in Stockholm, Swed., and thereafter it was held biennially beginning with the congress in Dortmund, Ger., in 1959.

International competition was dominated by European players through the 1930s. From 1927 through 1939 the men's singles was won by representatives of Hungary eight times, and of Austria and Czechoslovakia twice each; England's F. J. Perry won once, in 1929. When international competition was resumed after World War II, Czechoslovakia took the first men's singles title (1947), and then it went to England four times in a row, to J. Leach in 1949 and 1951, and to R. Bergmann (a naturalized English citizen who had won for Austria in 1937 and 1939) in 1948 and 1950. Thereafter, except for F. Sido's win for Hungary in 1953, the men's singles championships moved to the Far East, led by Japan (H. Satoh in 1952, and four in a row from 1954 through 1957), with Communist China coming on to win its first men's singles in 1959. The other events—men's doubles, women's singles and doubles, and mixed doubles, and the men's team (Swaythling Cup) and women's team (Marcel Corbillon Cup)—followed much the same pattern, although the United States, Yugoslavia, Rumania (especially in the women's and mixed doubles events in the 1950s), Germany, and Scotland managed to get in the winner's column on occasion. After the world titles, the greatest interest is generated by the European and the Asian championships.

**The Game.**—Table tennis is played by striking a pale, hollow celluloid ball ( $4\frac{1}{2}$ – $4\frac{3}{4}$  in. circumference, 37–39 g. weight, or 37–41 g. weight in the U.S.) with a racket (bat or, loosely, "paddle") over a net (6 in. high, 6 ft. long) fixed across a dark, nonreflecting table top (9 by 5 ft., 30 in. high). The blade of a typical racket is made of wood and is usually faced on both sides with stippled rubber to control the ball and to impart spin. The sponge-faced racket, which Japan used in winning a world championship in 1954, was banned under rules adopted by the ITTF in 1959.

The server's racket hits the ball behind his end of the table so that it bounces first on his side of the table, then over the net on his opponent's side. In U.S. tournament play, the server

cannot impart spin to the ball except by use of his racket. The ball is then struck to and fro directly over the net, after bouncing (volleying is illegal) until a point is scored by failure to make a good return. Service, after every 5 points, alternates and the winner is the player who first scores 21 points; but at score 20-all service alternates after each point. As in tennis, a game must be won by at least two points. In doubles, the ball must first touch the server's right half court and after passing over the net the receiver's right court; once in play, it may be placed anywhere on the table, as in singles, except that partners must alternate in returning the ball. One U.S. law prevents strictly defensive play.

The orthodox grip is assumed by "shaking hands" with the racket, as in lawn tennis, except that the table tennis racket or bat is not held at the end of the handle. The forefinger rests along the blade on the rear (backhand) side of the table tennis racket and the thumb on the forehand side. Slight variations from this grip are common. Many Asian players, including the Chinese and the Japanese, have used the "penholder" grip (handle held between forefinger and thumb, like a pen).

The basic shots are the push or half-volley, usually executed by meeting the ball with the racket in a near vertical position as the ball rises from the table; the forehand and backhand drives (characterized by topspin), executed by an upward stroke with the racket usually tilted toward the net; and the forehand and backhand chops (which impart underspin), executed by a downward stroke with the racket tilted away from the net and usually a defensive shot. There are many variations.

In the United States, the U.S. Table Tennis Association (USTTA) interprets the rules of the ITTF and publishes USTTA laws. There are comparable national organizations throughout the world. (P. W. R.; X.)

**TÁBOR**, a town in South Bohemia, Czech., lies on the Lužnice River, a tributary of the Vltava, 55 mi. (89 km.) S of Prague. Pop. (1961) 20,142. It was founded in 1420 as the regional centre of the militant Hussites (*q.v.*) by the more radical members of the movement, subsequently known as the Taborites, and led by Jan (John) Žižka. The Old Town is situated on a steep ridge rising from the right banks of the Lužnice; it is protected by ramparts and the large Jordan "pond" where the inhabitants once baptized their children. It has many important medieval buildings, including the town hall (1521), which houses the Hussite Museum. The town gate (*Bechyňská brána*) dates from 1420. In the central market place stands Žižka's statue. The square is fringed by crooked, narrow streets, planned to impede access by enemy intruders; underneath it extends a labyrinth of passages and cellars, also of tactical significance. Small-scale industry (agricultural machinery, textiles, and tobacco) has grown up at Tábor, which is a railway junction and nodal point in the road system. (H. G. S.)

**TABRIZ** (ancient TAURIS), the second largest city of Iran and capital of the Third ostan of East Azerbaijan province, lies at an altitude of about 4,400 ft. (1,340 m.) at the northern foot of Kuh-e Sahand, about 330 mi. (530 km.) NW of Teheran. It is almost equidistant from the Turkish and Soviet frontiers and lies in the valley of Talkheh Rud (Aji Chai, "bitter water"), which flows westward to Lake Urmia. Pop. (1956) 289,996. The climate is continental: hot and dry in summer and severely cold in winter. It is surrounded by hot springs and is in an earthquake zone liable to frequent and severe shocks.

The most notable ancient buildings are the Blue Mosque or Masjid-i-Kabud (1465–66), built by Jahanshah, and the citadel or Arg. The mosque, renowned for the splendour of its blue tile decoration, had by the mid-1960s been extensively repaired. The citadel, built as a mosque before 1322, was adapted to its present use in 1809. It is remarkable for its simplicity, size, and the excellent condition of its brickwork.

The process of modernizing the town was accelerated after World War II. Streets were widened, buildings erected, and public gardens laid out with fountains and pools. The new buildings include a railway station, the largest in Iran, the Ustandari (office of the governor general), and Tabriz University with its faculties

TABLE TENNIS TABLE

of arts, science, agriculture, medicine, and pharmacy. Just outside the city is a summer resort with the lake and pavilion of Shah Goli.

Tabriz is an important commercial centre with expanding industries. The principal product is carpets; others include soap, matches, paint, leather goods, cotton and wool textiles, and dried fruit and nuts. The city is a rail and road centre; it is linked by rail with Teheran and through Jolfa with the Soviet system. The extension of the railway from Tabriz to Turkey was under construction in the mid-1960s. An airfield lies east of the city.

The early history of Tabriz is unknown. The name is said to be derived from *Tap-riz* ("causing heat to flow"), a reference to the many thermal springs in the area. As Tauris, it was for a short time the capital of the Armenian king Tiridates III in the 3rd century A.D. It was rebuilt by Zubaïda, wife of Harun al-Rashid, in 791, after being destroyed by an earthquake. Similar disasters followed, in 858, 1041, 1721, and 1780. In the 13th century Tabriz twice escaped being sacked by the Mongols by the payment of heavy ransoms; and on its final submission it was made the capital of Il-khan Ghazan (1295-1304) and his successor. In A.D. 1392 it was taken by Timur (Tamerlane), and was made a provincial capital by his son Miran Shah. About 30 years later, the Kara-Koyunlu (Black Sheep) Turks made Tabriz their capital, and the Blue Mosque was built. It retained its position under the Safavid dynasty until 1548, when Shah Tahmasp I moved his capital westward to Kazvin (Qazvin), which was less exposed to Turkish attack. During the next 200 years Tabriz changed hands several times between Persia and Turkey. Under Nadir Shah (1736-47) it was the capital of northwestern Iran. In 1908 it became the centre of the Nationalist movement and has continued to play an important part in Iranian politics. Between 1900 and 1945 Tabriz was occupied five times by Russian troops. (M. V. S.-W.)

**TABU.** The basic meaning of the word tabu (taboo) in English is "forbidden," "prohibited," but it usually refers to actions barred by rules of manners or morals rather than of law; i.e., by social convention in which there are nonrational elements. It has also been extended to apply to any ritual distinction of persons or things sacred or accursed.

**Origin and Scope.**—The term is of Polynesian origin. The form *tabu*, which Capt. James Cook noted when he first discovered its use at Tonga (Friendly Islands) in 1771, was later used by the Tongans when they adopted a written alphabet, but they later came to write the word as *tapu*. This is the most common Polynesian form with *kapu* as a variant, and various speculative etymologies have been given for the literal meaning; e.g., *ta*, "to mark," "strike," *pu*, "exceedingly." In Melanesia, corresponding terms in form and meaning are *dabung* (Busama) and *tambu* (generally). The term and the concept are not always equivalent even in Polynesia: in Samoa, the notion of "forbidden" is expressed by *sa* and some similar Oceanic words have different overt meanings. *Tabu* in the Trobriands is a kinship term applying among others to a female cross-cousin or other relative appropriate for marriage, while in Dobu it means a magic charm to cause disfigurement or disease. On the other hand, notions very similar to tabu are found widespread ethnographically and expressed by a great range of linguistic expressions, as for example in Rhodesia by *tonda* among the Ila and *bwanga* among the Bemba, or *haram* in the Arabic-speaking world.

The concept of tabu was soon adopted into European languages and, by its suggestion of mystery and of being related to primitive religious ideas, provoked an extensive literature. A major contribution was made by Sir James G. Frazer in his article on "Taboo" in the 9th edition of the *Encyclopædia Britannica* (1875-89) and in *The Golden Bough* (1890). He regarded tabu as a system of religious prohibitions, attaining its fullest development in Polynesia but traceable under different names in most other parts of the world; and, as something sacred, he contrasted it with the concept of *noa* (a Maori word meaning "profane"). He also regarded tabu as the negative aspect of magic, the rules of prohibition as contrasted with the positive aspect of magic, the charms and formulas for securing success. Frazer gave an elaborate classification of tabooed things and acts, and his work was valuable in

bringing together a great mass of ethnographic information, in showing the range of the phenomena, and in stimulating enquiry into primitive religion; but his treatment was not sociological and many of his general ideas have not found modern support.

It should be emphasized that the meanings of tabu current in English and other western languages may be very different from those current in any one of the Polynesian or other communities in which the notion has been identified. Moreover, specific tabus are often not current for Polynesia as a whole. Frazer wrote that "the rule which forbids persons who have been in contact with the dead to touch food with their hands would seem to have been universal in Polynesia." But, while this rule was valid for many Polynesian societies, it did not apply, e.g., to Tikopia, where it was quite proper for someone who had handled a corpse to prepare and partake of food, even without washing his hands. Again, tabu has been treated as if it represented an integral, closely knit system of prohibitions, but this is not so even in any single Polynesian society. The range of items and activities to which *tapu* may be applied need have no obvious general pattern, though the major items usually show consistency.

**Nature and Functions.**—One simple usage of *tapu* (in Tonga) is as a conventionalized expression of respect: at the beginning of a public address the speaker may say *Tapu mo hou 'eiki* ("My respects to the chiefs"). In conversation when something has been said which by Tongan ideas of propriety may perhaps be regarded as disrespectful or improper—such as a reference to a part of the human body or to an animal—the expression *Tapu mo koe* (equivalent to "If you will excuse my mentioning such a matter") is interpolated.

To modern Polynesians *tapu* may mean no more than a thing that must not be interfered with. So a Tikopia man may tell his child not to touch a visitor's camera or fountain pen, saying "It is *tapu*," by which is meant not that the article in question has any particular quality of its own, but that interference with it is not allowed. Similarly in modern Melanesia a board set up on a tree with the word *tambu* on it may be simply a warning to people against going along a path or into an orchard, broadly equivalent to "trespassers will be prosecuted," or simply "keep off."

But the notion of tabu is usually much more complex. Generally it includes the idea that the object or action interdicted has some ritual quality, or that the sanction against a breach of the rule is extrahuman or supernatural. Very frequently this sanction is regarded as automatic in its action: a breach of tabu is followed logically and necessarily by some kind of trouble to the offender; e.g., lack of success in fishing or hunting, sickness, death of a relative. In ordinary terms this would be regarded as accident or bad luck, but to the people concerned it is regarded as a punishment for breaking the tabu. A person meets with an accident or has no success in his pursuit and, in seeking for its cause, he or others infer that he has in some manner committed a breach of tabu.

With some tabus, however, the sanction is not automatic, but is invoked by the person controlling the tabu, and is believed to consist in the power of a god or spirit to punish the offender. From this point of view, Frazer's equation of tabu with negative magic is inadequate, according to his distinction between magic and religion, for this kind of tabu should come in the religious category. Another theoretical equation of tabu with negative mana (*q.v.*) by R. R. Marett, also fails. These two concepts in their Polynesian setting belong to different categories; standing for efficacy and power of a supranormal kind, mana is not necessarily connected with tabu.

In general, tabu has a dual significance. Much attention has been paid to the apparent inconsistency between the notions of holiness or sacredness apparent in many kinds of tabu (the holiness of a Polynesian chief is tabu as part of his general character as a sacred leader) and the notions of uncleanness in others (contact with a menstruating woman may be tabu in a defiling sense). But common to both these ideas is respect, associated with the idea of not touching. It is not found, as Frazer thought, that primitive peoples can make no moral distinction between the conceptions of holiness and of pollution, nor is it paradoxical that

redness and prohibition should attach to the same object. Things that are sacred have some elements of prohibition attaching to them, but all things that are prohibited are not necessarily of sacred quality.

Tabus are often thought to be entirely irrational, even absurd, as in some societies regular tabus have important social functions, e.g., those against incest. Others have economic effects; e.g., food tabus that restrict the diet of pregnant women or of totemic clans. Some kinds of tabu are not always in operation, but are set up for specific purposes; e.g., those prohibiting fishing or picking fruit at certain seasons may be valuable in food conservation. Many tabu rules ritually symbolize important social relationships and may thus be a substitute for laws and form part of the moral code of the society.

**Theories.**—There have been many attempts at explanations of the origin of such beliefs and behaviour. One of the most ingenious was that of Sigmund Freud, who associated the concept of tabu with that of neurosis. He argued that tabus were generated in ambivalent social attitudes in which the social components largely replaced the sexual elements of the neurosis. The basis of tabu then is a forbidden action for which there exists a strong unconscious inclination. This may well hold for some (e.g., incest tabus) but ignores the fact that an essential feature of tabu is the freedom of the individual to restrictions imposed by social tradition. Moreover, much of the desire to break through the prohibitions of the tabu may be quite conscious; e.g., when tabus are placed upon food supplies.

Social anthropologists are not unanimous in their theoretical explanations, but there is broad agreement that the tabus current in any society tend to relate to objects and actions that are significant for the social order, and belong to the general system of social control. They may do this directly, as in emphasizing the status of chiefs and religious objects, or indirectly, as in the prohibitions on the killing or eating of totemic species which in themselves are of no particular significance but which, as indices of social units, form part of a symbolic framework for the society. It is often impossible to know why a particular action or article has been singled out for such respect behaviour. But a general assumption is that such ritualization of respect involves implicit recognition of danger in disturbing significant social relations.

See MORALITY, PRIMITIVE; PASSAGE RITES; PURIFICATION. See also references under "Tabu" in the Index.

**TABULATING MACHINES:** see OFFICE MACHINES AND APPLIANCES.

**TACHEOMETRY**, a method used in surveying for quickly determining horizontal and vertical distances. The term is generally applied to operations in which distance is obtained by the measurement of a small angle lying opposite a short known base. Tacheometric instruments usually make use of a detached base; as in the case of the range finder (*q.v.*), the base line is sometimes an integral part of the instrument. Because of its size, the ordinary range finder is not useful to the surveyor.

The instruments that make use of an external base may be divided into two groups: (1) those that make use of a fixed angle to measure an intercept on a distant staff, and (2) those that measure an angle subtended by a fixed base. In the latter case, the horizontal angle, subtended by a standard "subtense" bar of two metres and oriented at right angles to the line of sight, is measured on the circle of a theodolite (*q.v.*). In the former case, the

theodolite is equipped with stadia wires that intercept a portion of the length of a graduated rod held vertically at the distant point by two rays that include the fixed angle. A double-image type of tacheometer causes a portion of the image to be displaced with respect to another and the linear displacement is read on a horizontal graduated staff. The tacheometric instruments are generally theodolites or transits modified by the addition of the optical distance measuring devices and implemented by various self-reducing devices for finding the horizontal and vertical components of the slope distance.

See RANGE FINDERS; SURVEYING.

(K. S. Cs.)

**TACHINID FLY**, any species of the dipterous family Tachinidae (or Larvaevoridae), the larvae of which are internal parasites of other insects. As adults many tachinids superficially resemble house flies but are much more bristly, particularly on the abdomen; however, there is considerable diversity of form among the more than 5,000 known species. They range in size from 2 to 18 mm. Although most species are dull gray or black, some are marked with red, orange, or yellow, and a few are metallic green or blue.

Tachinids are of great importance in the control of destructive insects, particularly lepidopterous caterpillars and beetle larvae, and for this reason several species have been transported from one country to another to combat native or introduced pests. Outstanding examples include reduction of the sugarcane beetle borer in Hawaii by *Ceromasia sphenophori* from New Guinea, and control of the coconut moth in Fiji by a Malayan tachinid, *Ptychomyia remota*. *Centeter cinerea*, highly destructive of the Japanese beetle in Japan, has been brought to the United States to control that species. Caterpillars of the armyworm have been found locally to be 20 to 90% infested by larvae of red-tailed tachinids (*Winthemia*). *Compsilura concinnata*, introduced from Europe to control the gypsy moth and brown-tail moth, has been found to attack more than 200 species of caterpillars; in contrast, most tachinids are capable of parasitizing only a small number of hosts, often a closely related group of species; and a few have but one host. Some parasitize locusts, earwigs, squash bugs and related species, and a few other kinds of flies. Certain tachinids attack honeybees and silkworms, but these are not numerous. Many adult tachinids frequent blossoms to obtain nectar and thus serve as pollinators.

The means of entering the host has become highly evolved among Tachinidae. Some attach eggs to their victims, the larvae burrowing through the skin upon hatching. Others deposit living larvae, either directly upon the host or in situations allowing the larvae to attach to passing insects. Certain species lay their eggs on vegetation, which is eaten by caterpillars. Tachinid maggots usually breathe by an opening through the body wall of the host or by contact with its respiratory system. Larvae may remain within the host to pupate or may leave it. Most tachinids destroy their hosts, but others do not. (G. W. Bs.)

**TACHIRA**, a state in the Andean region of Venezuela bordering on Colombia. Area 4,286 sq.mi. (11,100 sq.km.). Pop. (1961) 399,163. Agriculture dominates the economy and coffee and sugar are leading commercial crops. Rural industry, closely related to agriculture, is to a considerable degree carried on in homes. San Cristóbal, the state capital and leading commercial centre, is on a trans-Andean highway about 34 mi. (55 km.) W of the border town of San Antonio. Relatively large deposits of coal are found at Labatera. La Alguitrana claims the distinction of having the first oil well (1878–79) in Venezuela.

Some inhabitants of Táchira belong to privileged groups who take great pride in the purity of their European ancestry.

(J. J. J.)

**TACHOMETER**, an instrument that indicates the speed of rotation of a shaft or machine element. The major types of tachometers are classed as (1) centrifugal, (2) electrical, (3) vibrating reed and (4) electronic.

Centrifugal tachometers employ a spindle driven by the shaft whose speed is to be measured. As the spindle turns, centrifugal force causes fly-weights that are attached to the spindle to be displaced away from the axis of rotation. These weights are re-

strained by springs. The position of the fly-weights and the rotational speed of the shaft are interrelated. Through a suitable linkage the position of the weights is calibrated in terms of rotational speed and is indicated by a pointer which is on the instrument scale.

One type of electrical tachometer uses a small permanent-magnet-field direct current generator driven by the shaft whose speed is to be measured. As the voltage output of the generator is proportional to the speed of the shaft, a voltmeter, which can be remotely located, is graduated to indicate speed. Another electrical type uses a small ammeter actuated by the current flowing in a circuit due to the charging and discharging of a condenser. The instrument spindle, which is driven by the shaft, in turn drives a switch to open and close the circuit. The current flowing is proportional to the number of "makes" and "breaks" of the switch and the ammeter is graduated in revolutions per minute.

The vibrating reed type of tachometer uses a series of thin steel reeds with natural frequencies ranging from low to high and corresponding to certain speeds. When an instrument of this type comes into contact with the machine one or more of the reeds will vibrate in sympathy with the machine and indicate the rate of speed. Such a tachometer is not driven by the shaft but responds to vibrations of the machine.

Electronic tachometers are of two types. The stroboscopes employ the persistency of human vision to detect the change in speed viewed under a flashing light. When the flashes are synchronized with the shaft's rotational speed, the shaft appears stationary. There is no need for mechanical contact with the shaft. This feature is important for devices of very small power output, for contact between spindle and shaft actually slows down such machines. The other electronic-type tachometer is basically a revolution counter that receives its impulse from a pickup (often magnetic), counts the revolutions in each second and displays the count directly as revolutions per minute. (R. A. O.)

**TACHYLYTE** (TACHYLITE), in petrology the glassy variety of basic igneous rock such as basalt (*q.v.*) or diabase. Tachylytes are black in colour, with a pitchlike or resinous lustre, and in the thinnest sections are typically brown and translucent, the glass being crowded with granules of magnetite. They are found only under conditions which imply rapid cooling, and are much less common than the corresponding acid volcanic glasses, principally on account of the greater fluidity and greater power of crystallization which basic lavas possess. The principal mode of occurrence of tachylyte is as a chilled edge or selvage to thin dikes or sills of basalt or diabase. This edge may be only a fraction of an inch in thickness and merges inward into crystalline basalt. Tachylytes of this nature are common among the Tertiary igneous rocks of the Inner Hebrides of Scotland (Skye and Mull).

Exceptionally, tachylyte constitutes almost entire lava flows, as in the Hawaiian Islands. The rapid cooling of the highly fluid lavas of this region has inhibited crystallization, giving rise to vast floods of basaltic glass containing only minor amounts of crystalline material. Lastly, tachylytes occur as scoria, or bombs, thrown out by basaltic volcanoes. These are well known at Stromboli, Etna and in Iceland. Tachylytes readily undergo weathering and alteration, and are converted by oxidation and hydration into palagonite, a red, brown or yellow cryptocrystalline material. (C. E. T.)

**TACITUS, CORNELIUS** (c. 56–c. 120), historian whose accounts of 1st-century Roman history are still read for their vividness, irony, and stylistic brilliance.

**Family and Career.**—Tacitus has left the imprint of his personality upon his work but little evidence about his life, and here we are in debt to the letters of the younger Pliny (*q.v.*). Their connection may go back a generation. Pliny's uncle, the elder Pliny (*q.v.*), knew a Cornelius Tacitus, Roman knight and procurator (financial officer) of Gallia Belgica, who may have been the father or uncle of the historian. Tacitus belonged probably not to the old Cornelian aristocracy but to a rising family of Cisalpine Gaul or, more probably, Gallia Narbonensis, which had taken the Cornelian name on receiving Roman citizenship. The date of his birth was c. 56; his first name is given as Publius or Gaius. His

family circumstances and his own ability opened the way to higher education, a good marriage, and an official career.

Tacitus studied rhetoric and took up advocacy under two leading orators, M. Aper and Julius Secundus. When he wrote the *Dialogus* he laid the scene in this period (74/75) and introduced them into the discussion. In 77 he was betrothed to the daughter of Agricola (*q.v.*) and his marriage later in the year secured him influential support. Meanwhile he had entered on public office with the vigintivirate (one of 20 appointments to minor magistracies, and a military tribunate, followed by the quaestorship probably in 81. In 88 he became praetor and a member of the priestly college that kept the Sibylline Books. Then he held a provincial post for four years, possibly in command of a legion, and was away from home at Agricola's death in 93. On his return he experienced the last years of Domitian's oppression. In 97, under Nerva, he gained the consulship and delivered a funeral oration over Verginius Rufus, the famous soldier who had refused imperial power in 68–69. By now he was celebrated for his oratory and courted by aspiring advocates; but in 98 his personal feelings led him into literature: he wrote a biography of Agricola, followed by the *Germania*, an ethnographical study of topical significance. In 100, along with Pliny, he successfully prosecuted Marius Priscus for extortion in Africa. Then he wrote the *Dialogus*, and turned to political history with the *Historiae*. This work was already published when he crowned his public career with the proconsulate of Asia in 112/113. Thereafter his life was devoted to the *Annals*; he died in the early years of Hadrian's reign (c. 120).

**Works.**—As a rhetorician Tacitus knew the various genres of literature, as well as oratory, and he applied the appropriate style to each of his works; but his historical instinct, trained by political experience, was always dominant. The *Agricola* (98) is a biography of his father-in-law, Gnaeus Julius Agricola, the famous governor of Britain (77 or 78–84) under Domitian. It is laudatory but systematic, and also describes the geography of Britain and the Roman conquest that culminated in Agricola's campaigns. Tacitus depicts him as a man of true Roman virtue, who defended the state without useless defiance or craven servility toward an evil emperor. He aimed at justifying moderate, efficient men like Agricola (and himself) against the criticism of those who were indulging their freedom under Nerva to glorify the martyrs of Domitian's reign.

The *Germania* (*de origine et situ Germanorum*; 98) describes the geography and customs and the various tribes of Germany in a regular ethnographical way. Tacitus relied upon written information, chiefly from the elder Pliny. He shows the simple virtue as well as the primitive vice of the Germans: here was something of the old Roman morality in contrast to the laxity of contemporary Rome. The Germans emerge as a formidable foe, weakened only by intertribal feuds. Against them the empire needed unity and strength. But, although Trajan was on the Rhine at this time, the *Germania* is hardly a political brochure either urging him to action or defending his caution.

The *Dialogus de Oratoribus*, although set in Tacitus' youth, was written after the reign of Domitian. Its Ciceronian style arises from its form and subject matter and does not point to an early stage of stylistic development. The discussion balances the practical case for oratory against the pleasure and virtue of a poet's life: in any event oratory has declined since republican days, owing to lower standards of morality and education. The political licence of the republic had encouraged true eloquence; the imperial peace destroyed its sources of inspiration. The work may be dated shortly after 98—perhaps in 102, if the dedication was to Fabius Iustus as consul—and reflects Tacitus' mood at the time when he renounced oratory for history.

In the *Historiae* (*Historiae*) Tacitus treated the period from Jan. 1, 69, with Galba in power, to the death of Domitian in 96. Only books i–iv and part of book v survive (for the years 69–70). They cover the fall of Galba and Piso before Otho (book i); Vespasian's position in the East and Otho's suicide, which makes way for Vitellius (book ii); the defeat of Vitellius by Vespasian's generals (book iii); and the beginning of Vespasian's reign (books iv–v). The original work contained 12 (or 14) books (it is only

known that the *Histories* and *Annals*, both now incomplete, totaled 30 books). To judge from Pliny, several books were ready by 105, the writing well advanced by 107, and the work complete by 109. Then Tacitus proceeded not to the reigns of Nerva and Trajan (as he had lightly promised in the *Agricola*) but to the early principate.

The *Annals* (*ab excessu divi Augusti*), in traditional form, covered the period from the death of Augustus and accession of Tiberius in 14 to the end of Nero's reign in 68, thus linking up with the *Histories*. There survive only books i–iv, part of book v and most of book vi (these sections on Tiberius, from 14 to 29 and from 31 to 37), and books xi–xvi, incomplete at beginning and end (on Claudius from 47 to 51 and Nero from 51 to 66). The original work contained 18 (or 16) books. There is some evidence of groupings of six: books i–vi on Tiberius (subdivided into books i–iii on Tiberius and Germanicus, books iv–vi on Sejanus and Tiberius), and books vii–xii on Gaius (Caligula) and Claudius. To judge from his references to Parthian power, Tacitus had written most of books i–vi by 114 (Trajan's offensive against Parthia). If a reference in book ii, 61 to *mare rubrum* ("Red Sea") as the Roman frontier means the Persian Gulf, he was touching up these books in 116–117 (after Trajan's victory and before Hadrian's withdrawal); but the phrase refers rather to the Red Sea proper (after the annexation of Arabia in 105/106). In any event he probably completed the work early in Hadrian's reign.

**Sources.**—For the period from Tiberius to Vespasian Tacitus drew upon earlier annals and monographs, which contained material from public records, official reports, and contemporary knowledge, set out in chronological order. The work of Aufidius Bassus and its continuation by the elder Pliny covered these years; both historians also described the German wars. Among other sources may be noted Servilius Nonianus (on Tiberius), Cluvius Rufus and Fabius Rusticus (on Nero), and Vipstanus Messalla (on the year 69). They are only names to us, but much of their material will lie beneath Tacitus' narrative. He did more than combine his authorities: he consulted, where necessary, the senatorial records, the official journal, and such firsthand information as a speech of Claudius, the personal memoirs of the younger Agrippina, and the military memoirs of the general Corbulo. For Vespasian's later years and the reigns of Titus and Domitian he worked directly from official records and reports, using his own and his friends' personal knowledge.

**View of History.**—In studying Tacitus' historical attitude it is not enough to cite his personal reaction to Domitian's terrorism: his experience was more varied and constructive. While he condemned the maladministration and disorder of the republic, he had seen the corrupting effect of power upon Domitian and of powerlessness upon the Senate. He had lived through a double crisis of imperial policy when Nerva and Trajan came to the succession, and had witnessed the liberal Nerva at the mercy of the praetorian guard, and the benevolent Trajan regimenting the state. His own career had revealed to him, in court and administration, the play of power behind the facade of the principate. His experience intensified his temperamental pessimism. In the *Histories* he could describe, with overtones, how Galba's policy of adoption failed, where Nerva's was effective; how soldiers outside as well as inside Rome might make or unmake emperors; how Vespasian's restoration of order ominously degenerated into Domitian's tyranny. But, as he thought on the parallels, they stretched back to Augustus. Were they, then, symptomatic of a deep-rooted condition of the principate? It was historically logical to take up this problem in the *Annals*. The republic, he argues, had suffered under personal power but only at intervals in a course of freedom: it was Augustus who contrived permanent domination. The proof of this lay in direct transmission of power: hence the significance of Tiberius' accession in the *Annals*. Its effect was the corruption of public conduct between the extremes of despotism and servility. The loss of freedom cost Rome its virtue, and the history of the principate was a pattern of the consequences. Tacitus could claim impartiality because he was confident of his basic interpretation. Tacitus' standards were those of traditional Roman behaviour, and he conceived history in personal terms. This attitude influenced his choice of material and dictated the emphasis of his de-

scription. His facts are generally accurate: only his arrangement distorts their impression; for he will make his view of a character explain every significant action. On the critical point of Tiberius' policy he had found a tradition—it is also in Dio Cassius—of the emperor as a man who applied his words and moods to all uses except the indication of his mind: Tacitus used this feature to illustrate his theme of Tiberius' universal hypocrisy. Similarly Claudius' weaknesses are total, Nero's instability is essentially evil. He heightens the contrast of characters: Tiberius and Germanicus, Claudius and his wives, Agrippina and Nero. Yet, when his composition is analyzed, he provides the evidence with which to modify the starkness of his interpretation. Even where he appears to neglect imperial administration and its benefits, this is not merely for lack of interest: routine efficiency, in his view, is subservient to degeneracy in high places. His political interpretation is on the human plane, following the example of Sallust: he leaves the individual free to choose good or ill and be judged accordingly at the bar of history. Though he refers to the anger of the gods and the malignity of fate, such expressions appear unsystematic and casual; for in these matters Tacitus was a conventional well-bred Roman. This is equally apparent in his attitude toward Jews and Christians, as far as he distinguished between them, both in his view objectionable for their un-Roman religion, the latter also for their "hatred of the human race" (*odium humani generis*).

**Method and Style.**—Roman historiography used the old "analytic" (yearly) form as a framework of chronology. This allowed the convenient entry of official data and had a traditional appeal through its ceremonial appearance. It also provided literary advantages. The formal arrangement enclosed elaborate episodes, and the contrast varied the tension of the narrative. This procedure is less marked in the *Histories*, where the extant books describe extensive operations during a short period; it is exploited fully in the *Annals*. Tacitus applied all the techniques of rhetoric that a historian had available: geographical surveys, ethnographical digressions, set battle pieces, public debates, character summaries, and characterizing speeches. But they became less conventional as he integrated his methods in the *Annals*, under a dramatic conception of history. Hellenistic historiography had given the Romans a technique of dramatic writing which set a scene and brought the actors before the mind's eye, with direct emotional impact, heightened by colourful, poetic language. It owed much to Roman epic, the ally of Roman history. An imaginative historian who interprets in terms of character and situation and who thinks visually will be, above all, dramatic. Tacitus was master of this art. But it was not art for art's sake. He fuses his portrayal of single episodes with his historical theme: his writing is the projection of his thought, especially in the *Annals*. The dramatic element is found in construction, when books end with catastrophes involving the death of notable persons. The Roman tradition of dignity limited the cheap use of sordid details, and Tacitus practises extreme concentration of effect. This often distorts his picture, especially when he has exaggerated his characterization. It also leads to the suppression of explanatory matter before and after his literary spotlight falls on the action. In military accounts, since he focuses attention upon the battle scene, neglecting the strategic situation, he is to this extent "unmilitary." But Tacitus seizes direct control of his reader's mind and imagination.

Above all, Tacitus shows his genius in his use of the Latin language, with its qualities of strength, colour and rhythm. His style is packed, it breaks the easy balance of sentences with striking asymmetry, and it plays on word order and variation of syntax. In this he owes a debt to Sallust. He writes in the grand style, helped by solemn and poetic vocabulary, and with the passion of a satirist. The historian lives in the writer, and his style displays its strongest features in the early books of the *Annals*, where his thought is most severe. As for his epigrams, which blast so many reputations, the brilliant trick of contemporary rhetoric has become the last word of a considered historical judgment: the Tacitean epigram is the lightning that flashes from the dark cloud under which he has placed the principate. One could mention Poppaea, who "had everything except honour" (*Annals*, xiii, 45;

*huic mulieri cuncta alia fuere praeter honestum animum*), or Roman imperialism: "where they make desolation they call it peace" (*Agricola*, 30; *ubi solitudinem faciunt, pacem appellant*).

**Later Reputation.**—The immortality that Pliny prophesied for Tacitus remained in abeyance for two and a half centuries—unless the story that the emperor Claudius Tacitus (275–276) honoured and republished him is true—until Ammianus Marcellinus imitated his style in continuing his work. A thousand years later the Renaissance scholars resurrected him and studied his evidence for statecraft. The French welcomed his literary art, even before the Revolution made his history fashionable. Modern scholarship has probed his facts, examined his views, and analyzed his style, so that we may now set him critically among the immortals.

**TACITUS, MARCUS CLAUDIUS**, Roman emperor A.D. 275–276, was an elderly and wealthy senator. On the murder of Aurelian in 275, after a succession of usurpers and emperors who were by origin career officers, the army council invited the Senate to select a nobleman. After six months' delay, their choice fell upon Tacitus. His reign was ineffectual and lasted less than seven months; after the equally short and unimpressive rule of his half brother Florian, the army again chose a career officer, Probus.

(Jn. R. M.)

**TACLOBAN**, capital of Leyte Province, Republic of the Philippines. It is the largest city and distributing centre on the islands of Leyte and Samar and the only port east of Cebu with terminal facilities. Tacloban played an important role in World War II. On Oct. 20, 1944, U.S. Gen. Douglas MacArthur's forces landed at several points on the coastal plain along Leyte Gulf south of the city; from there the U.S. forces pushed rapidly northward to capture Tacloban on Oct. 21 and then westward to Ormoc, the largest Japanese stronghold and supply base on the west coast of Leyte. From the time of its capture until U.S. troops captured Manila, Tacloban was the temporary capital of the Philippine Commonwealth. Pop. (1960) 53,551.

(An. C.)

**TACNA**, the southernmost department of Peru, is bounded on the southwest by the Pacific Ocean, on the north by Moquegua and Puno, on the east by Bolivia, and on the south by Chile. It has an area of 5,701 sq.mi. (14,766 sq.km.) and a population (1961) of 69,176. The southwestern portion of the department is a part of the Peruvian coastal desert, and settlement there is dependent on irrigation provided by the Río Sama and the Río Locumba. The eastern part of Tacna is in the high Andes. The one area of concentrated settlement is around the town of Tacna, the capital. On the irrigated lowlands sugarcane, cotton, grapes, fruit, and alfalfa are grown, while the few Indian inhabitants of the highlands produce wheat, barley, and potatoes and raise sheep and alpacas. Among the known but little exploited minerals of the department are silver, borax, gypsum, and sulfur. In 1956 the Peruvians began the development at Toquepala of what it was believed might prove to be the largest copper ore deposit in the world. The outlet for the copper would be through the port of Ilo.

The town of Tacna and its port of Arica, 48 mi. (77 km.) S and connected to the capital by rail, became famous during the long

border dispute with Chile. See TACNA-ARICA DISPUTE.

(P. E. J.)

**TACNA-ARICA DISPUTE**, a controversy involving title to territory that belonged to Peru before the War of the Pacific (q.v.). The treaty ending the conflict between Chile and Peru in 1883 provided that Tacna-Arica should be governed by Chile for a period of ten years and at the end of that time a plebiscite should be taken to decide title to the territory, the party suffering loss of the territory to receive \$10,000,000 from the other. Failure to agree on terms of the plebiscite ended in the breaking off of negotiations many times—in 1893, 1901, 1905, 1910, and 1913. In July 1922 the two parties accepted U.S. Pres. Warren G. Harding as arbitrator. After Harding's death, Pres. Calvin Coolidge took the responsibility. In 1925 he recommended that the plebiscite be held and for this purpose named a commission headed by Gen. John J. Pershing. The commission went to the area but failed to work out a solution. Following this failure, the proposal by the U.S. secretary of state, Frank B. Kellogg, that Tacna-Arica be ceded to Bolivia was accepted by Chile but rejected by Peru. In July 1928 Chile and Peru resumed direct negotiations and on Feb. 21, 1929, reached a settlement providing that Tacna should go to Peru and Arica to Chile. Chile agreed to pay Peru \$10,000,000 and to carry out certain construction works in the city of Arica. See also ARICA; TACNA.

(J. J. J.)

**TACOMA**, a city in western Washington, U.S., a port of entry and the seat of Pierce County, lies on Commencement Bay, head of navigation on Puget Sound, at the mouth of the Puyallup River, 30 mi. S by water of Seattle. From Tacoma can be seen Mt. Rainier, 50 mi. (80 km.) E (see MOUNT RAINIER NATIONAL PARK); via the Narrows Bridge the city has easy access to the Olympic National Park (q.v.).

From Commencement Bay in 1841 Lt. Charles Wilkes, commander of a U.S. exploring expedition, launched the first survey of the Pacific Northwest. Wilkes commented in his official journal upon the surrounding waterways: "Nothing can exceed the beauty of these waters, and their safety . . . I venture nothing in saying, there is no country in the world that possesses waters equal to these."

Except for the activities of the Hudson's Bay Company at Ft. Nisqually, there was little in the way of white settlement of the area before 1868. In that year, its original name—Commencement City, after the bay which Wilkes described—was changed to Tacoma, when Gen. Morton Matthew McCarver platted a new city in anticipation of its selection as the western terminus for the Northern Pacific Railway. The new name was a corruption of "Tahoma," the Indian name for Mt. Rainier.

Tacoma was incorporated as a city in 1875 under the laws of Washington Territory. It operates under a council-manager form of government in effect since 1953. Its population of 147,979 in 1960 was about 95% white; many of its citizens are of Scandinavian heritage, typical of the coastal cities of Washington. Tacoma is the central city of a standard metropolitan statistical area comprising Pierce County, with a population in 1960 of 321,590, a gain of 16.6% in the decade. (For comparative population figures see table in WASHINGTON: Population.)

Tacoma's principal manufactures include lumber and lumber products, aluminum, copper and copper by-products, ferroalloys, castings, and mineral wool. Electrochemical plants produce caustic and chlorine. Several candy manufacturers ship nationally and overseas, and men's wearing apparel is also a leading industry. Heavy cranes and logging equipment are manufactured to supply the needs of forest industry. Boatbuilding yards produce fishing boats and pleasure craft as well as watercraft to supply the armed services, marking Tacoma as one of the largest boatbuilding centres on the Pacific coast. Several major armed services installations, including Ft. Lewis, McChord Air Force Base and Madigan Army Hospital, were established nearby.

The University of Puget Sound (Methodist, founded 1888) and Pacific Lutheran University (established 1890) are located in the Tacoma area. The city also serves as headquarters for the Washington State Historical Society, whose five-floor museum overlooks Commencement Bay. The city maintains over 35 parks, compos-

ing a total of more than 1,700 ac.; the largest is Point Defiance Park, whose grounds contain a public yacht basin, a zoo, landscaped gardens, and also the restoration of old Ft. Nisqually.

(B. M. L.)

**TACONIC MOUNTAINS**, a hilly upland about 125 mi. (200 km.) long (north-south) and 10 to 25 mi. wide, mainly within eastern New York State. Its southeastern corner lies near the junction of New York, Massachusetts, and Connecticut. Its northern end is about 12 mi. NW of Rutland, Vt. Most summits are under 2,200 ft. (670 m.) elevation. Mt. Everett, in southwestern Massachusetts, is the highest point (2,604 ft. [793 m.]). The Taconics are separated from the more rugged Green Mountains and Berkshire Hills to the east by discontinuous lowlands developed on folded marble strata, as in the Rutland Valley of Vermont and the Stockbridge Valley of Massachusetts. The more durable rocks of the Taconic upland, including mainly Cambrian and Ordovician slates and phyllites, also rise boldly above the shales and marbles of the Hudson Valley-Lake Champlain lowlands to the west. Structurally, the rocks of the Taconics are believed to have been highly folded and overthrust from the east upon weaker, younger beds during the Taconic revolution, a crustal disturbance that closed the Ordovician Period in eastern North America.

The upland is covered with a mixed broadleaf-needleleaf secondary forest. Taconic State Park, an interstate park near the southern end of the upland, is the major developed recreational area.

(J. E. V. R.)

**TACONITE**. The name taconite was applied originally to an iron-bearing formation of supposedly Taconic age (Cambrian to Ordovician). Though this was an error the name was associated thereafter with iron-bearing rocks on the Mesabi Range in northern Minnesota consisting of chert (fine-grained quartz), magnetite, hematite, several silicates as minnesotaite, greenalite, stilpnomelane, and amphibole, and siderite. The rocks were originally chemical precipitates which now form beds of a maximum thickness of 750 ft. and a length of about 100 mi. along the strike. Their extent down the dip is unknown. In this taconite are found the high-grade iron-ore bodies which have supplied most of the iron of the U.S. As all taconite contains on an average 27% of chemically combined iron, it is considered the largest potential reserve of ore in the U.S. About 5,000,000,000 to 6,000,000,000 tons of it are near enough to the surface and contain sufficient amounts of magnetite so that its concentration to a high-grade product was in an advanced stage of development by the second half of the 20th century, and shipments of taconite concentrate and agglomerate were being made.

See also **MINNESOTA: Mining and Lumbering**.

See J. W. Gruner, *The Mineralogy and Geology of the Taconites and Iron Ores of the Mesabi Range, Minnesota* (1946). (J.N. W. G.)

**TACTICS**, the art and science of fighting battles, is concerned with the approach to combat, the disposition of troops, the use made of various arms, and the execution of movements for attack or defense. It is distinguished from military strategy, which consists of planning for the war as a whole, the disposition of forces among the theatres of operation, and the direction of the campaigns leading up to battle (see **STRATEGY**). Karl von Clausewitz, the 19th-century Prussian military theorist, defined tactics as "the formation and conduct of single combats in themselves" and strategy as "the combination of single combats with each other. . . . In other words, strategy forms the plan of the war, maps out the proposed course of the various campaigns which compose the war, and regulates the battles to be fought in each."

No matter how precisely the two terms may be defined, however, there is seldom any fixed line of demarcation. Strategy is frequently limited by the tactical potentialities of the forces involved, and tactics in turn depend on such strategic considerations as the planning and conduct of campaigns. Actually, the two overlap more often than not. In recognition of this fact, the term "grand tactics" gained currency during the Napoleonic era, and 20th-century military commentators have used the phrase "operational strategy" to describe concentrations of such major units as corps and divisions in preparation for battle.

Designations of this sort, unfortunately for clarity, are the exception. As a rule, the student of war must appraise each operation individually and supply his own distinctions.

Following a discussion of the basic elements of tactics, this article is divided into the following sections:

- I. Tactics of the Ancient World
  1. The Greek Phalanx
  2. The Tactics of Epaminondas
  3. The Greco-Macedonian Tactical System
  4. World Conquest
  5. The Rise of Rome
  6. The Battle of Cannae
  7. Tactics of the Cohorts
  8. Tactics of the Empire
- II. The Cavalry Cycle
  1. The Byzantine Horse-Archer
  2. The Byzantine Tactical System
  3. Tactics of the Franks
  4. The Decline of Infantry
  5. Medieval Tactics of Europe
  6. Longbow and Halberd
  7. Early Victories of Gunpowder
- III. The Military Renaissance
  1. The Fall of Constantinople
  2. Pike and Arquebus
  3. Maurice of Nassau
  4. Gustavus Adolphus and the Thirty Years' War
- IV. The Age of Linear Tactics
  1. The New Age of Moderation
  2. The Wars of Louis XIV
  3. The Tactical Theories of Marshal Saxe
  4. Frederick the Great
- V. Napoleon and 19th-Century Tactics
  1. The American Revolution
  2. French Revolutionary Tactics
  3. Bonaparte's Early Victories
  4. Tactics of the Empire
  5. Wellington's Tactics
  6. Half a Century of Transition
  7. The American Civil War
- VI. World War I
  1. The Battle of the Marne
  2. Deadlock on the Western Front
  3. The Offensives of 1917
  4. The Mobile Warfare of 1918
- VII. World War II
  1. The Post-World War I Reaction
  2. Early German Victories
  3. The War in the Pacific
  4. U.S. Amphibious Victories
  5. Wide Variety of World War II Tactics
- VIII. Nuclear Age
  1. War in Korea
  2. Tactics After Korea
  3. Later Tactical Organization; Vietnam
- IX. Naval Tactics

**Opposite Poles of Tactics.**—The elements of tactics are dual in character. Attack and defense, cohesion and dispersion, protection and mobility, missile and shock effect, moral and material values—these elements have been changeless throughout the ages, regardless of variations in arms and communications. The barbarian's bow and arrow was as effective a missile weapon in its day as the machine gun in its, and elephants were esteemed for shock effect many centuries before the invention of the tank.

Seldom do armies decide arbitrarily on the tactics they will adopt. The swing from one pole to another is nearly always influenced by geographical, climatic, and economic factors. Nomads of the plains become cavalry warriors from necessity rather than choice, just as mountaineers fight on foot. Primitive tribes and nations, unsure of their military skill, were drawn toward the cohesion of the human wall, or phalanx. As such peoples grew in strength and confidence they tended to adopt formations of dispersion, which are better suited to aggression. Thus the Romans of the early city-state fought in an eight-rank phalanx, but the Romans of the conquering republic developed that marvelously flexible tactical instrument known as the legion (*q.v.*).

One of the most cherished delusions of the ancient world was the belief that a formation had a shock effect in proportion to its depth. But adding ranks to the phalanx did not add to the material might of the attack; it merely contributed to the moral impetus of the attackers. Shock effect is rarely the product of

an actual physical impact. The shock is communicated to the soldier's mind rather than his body, and during the cavalry age he was morally defeated by his dread of being trampled, though horses seldom ran down foot soldiers who stood their ground.

**Principles of Tactics.**—Basic tactical principles are few and simple. The complexity and difficulty appear when such principles as surprise, secrecy, deception, security, and the gathering of intelligence are put into actual practice.

So obvious are the tactical advantages to be gained by deception and surprise that they are sought instinctively by primitives. Both principles are combined in that most primitive of tactics, the ambush. Even wild animals know enough to hide while lying in wait to attack. Yet the ambush is one of the most effective tactics of 20th-century warfare; it was used by both British and German armoured columns in the complicated North African desert campaigns of World War II and by the Vietcong in Vietnam in the 1960s.

It is hardly necessary to add that surprise depends on the degree of secrecy with which a general masks his intentions and capabilities. The moral turning point of the American Revolution came in 1776 when George Washington crossed the ice-choked Delaware River with a supposedly beaten army and killed or captured nearly all troops of three German mercenary regiments sleeping off a Christmas celebration at Trenton. This surprise would not have been possible without the American general's accurate intelligence of the enemy's vulnerability. Nor could it have occurred if the German officers had enforced security precautions in keeping with the defense of an outpost. A famous example of tactical deception was provided a week later when Washington cheated the British of an almost certain victory. Trenton was the locale again as Lord Cornwallis brought his adversary to bay with a materially superior army. A British attack had been ordered for the following morning, but the Americans left their campfires burning and slipped away in the darkness. Cornwallis' first intimation of the escape came at daybreak when he heard cannonading ten miles in his rear as Washington defeated a detachment of British reinforcements in the small battle of Princeton.

So essential is intelligence to the tactician that a good spy is sometimes worth more to an army than a good general. Reconnaissance patrols, prisoner interrogations, and observation or listening posts also play an important part in arriving at an estimate of an enemy's intentions and capabilities.

Security, like secrecy, is maintained in all military ages by unremitting vigilance. Although the firepower of missile weapons has often been given the sole credit for the prolonged stalemate in World War I, violation of age-old principles of tactics cannot be overlooked. Several promising Allied offensives met failure because surprise and deception were sacrificed to make possible the tremendous artillery "preparations" which had no decisive effect on an enemy burrowed deep into the earth. Such large quantities of shells were required for these bombardments that the area and extent of the impending offensive were revealed to the enemy by aerial photographs of ammunition dumps.

**Tactical Formations.**—Far back in man's past primitive ancestors perceived that superior numbers did not always make for superior force. A great deal depended on the tactical direction and speed with which this force was applied, and the solution was to group fighting men so that they could give one another the most support while doing the most harm to the enemy. This was the beginning of tactical wisdom.

The two basic formations are the line and the column, which differ only by 90° of the compass. In other words, a column of men in four files, facing north, has only to execute a "right face" to become a line of four ranks, facing east.

Neither of these formations is useful for all tactical purposes. Although the column is best adapted to marching and maneuver, its narrow front and vulnerable flanks are liabilities in combat. The line lacks depth and mobility, but it is more suitable for deployment on the battlefield. Mention should also be made of two other formations which appear less frequently in the chronicles of war—the hollow square and its counterpart, the 360° perimeter. Some stout stands have been made by men facing outward in all

directions, but the defect of such formations is that ability to maneuver is sacrificed.

In the prehistoric past it was evident that forming warriors into a line or column was not enough. Some attention also had to be paid to problems of deploying them so as to make the best of both shock and missile weapons. When men learned to fight on horseback, a cavalry arm came into being. The "eyes" of the primitive army, when used for scouting and reconnaissance, horsemen were also effective for pursuing a broken foe. A crude artillery arm appeared as early as the 8th century B.C., when the Old Testament dates engines of war (*q.v.*). Not even the tactical ancestor of the tank was lacking. Armoured chariots manned by archers and spearmen led the infantry in battles on the plains of Mesopotamia many centuries before the Christian era.

**The Tactics of Attack.**—Descriptions of battles are apt to give the impression that victories are won entirely by physical pressure, as measured by the casualties inflicted. It has been the experience of history, on the contrary, that moral forces play a much larger part in the outcome than material means. An army's combative spirit is not often broken because the ranks have been so thinned that the survivors are crushed by sheer human tonnage. They are beaten because of their conviction that further resistance is hopeless, and it is the business of the tactician to convince rather than crush his opponents.

The test may be found in the fact that casualties of 30% are usually the most an army can endure without losing combative spirit. Yet seven men out of ten are still able to fight, and it may be that they outnumber the entire force of adversaries who accepted battle with a numerical disadvantage. History records instances of losers being routed while still possessing a two-to-one numerical superiority. They were not crushed; they were simply convinced.

The methods of creating a conviction of defeat may be reduced to a few plans of attack which repeat themselves throughout history. Most simple of all is the plain frontal assault all along the line. Justifiable and even desirable under some circumstances, it is as a rule the resort of unimaginative generalship. As for the direct rear attack, it is so rare as to be associated only with ambush or pursuit.

At an early age it was discovered that armies, like the individuals composing them, dread an attack from the flank or rear. An assault from one side or another is not enough, since an adversary can face in the new direction, whereupon the effort becomes a mere frontal attack. In order to deliver a true flank attack, part of the offensive force must fix the enemy's front, perhaps even defensively, while the assault force swings around to strike simultaneously from the side. If this force can make a wide enough swing to threaten an opponent's rear, the attack becomes a single envelopment. And in instances when the rear is assailed from both sides with concentric thrusts, a double envelopment is the result. Neither a flank attack nor envelopments may be possible when a general secures his flanks with natural obstacles. In that case it is sometimes possible to create two new flanks by rupturing an adversary's front and driving through the gap to strike at his rear. That is the battle of penetration and it has some distinguished victories to its credit.

In any event, the effectiveness of the attack is in direct proportion to the conviction of defeat it can instill. As evidence, history is filled with occasions when the casualties of a beaten army were the result rather than the cause of defeat.

**Offensive and Defensive Tactics.**—The relative merits of the offensive and defensive have been subjects of argument in all military ages. From one century to another each has dominated in turn, the new cycle being brought about by the introduction of new weapons or tactics.

The attacker is usually able to choose the time of the assault and sometimes the place as well. If there are several points where the blow might fall, he has an opportunity to utilize the principles of deception and surprise against an opponent who must prepare as best he can to meet every alternative.

The defender often has the advantage of choosing and fortifying his own ground, but at least temporarily he must concede the

initiative to the enemy. In most instances, of course, he expects to regain it by means of a decisive counterattack after exhausting his adversary or placing him in an unfavourable position. Passive defenses are seldom the resort of a general who retains freedom of action, though there are exceptional occasions when the object is to inflict crippling casualties on a rash enemy.

Cordon defenses are put into effect along a frontier where troops can be thinly dispersed and quickly reinforced by reserves in the event of trouble. The mobile, or elastic, defense is based on the theory that if the enemy makes a penetration his flanks will be open to counterattack. As for the so-called defensive-offensive action, it merely implies that the defender has planned from the beginning to launch a counterstroke when he has an opportunity.

Breaking off contact with the enemy is a delicate operation calling for that specialized form of the defense known as a delaying action. The rear guard force holds just long enough to compel the pursuer to deploy, then pulls back to the next prepared position before becoming seriously engaged. In a two-line delaying action the first and second lines retire through each other in turn until the main body of troops is out of danger.

The ideal instrument would be an army equally formidable in offensive and defensive tactics, but there have been few such in military chronicles. Probably the most effective combination throughout history has been the strategic offensive and tactical defensive. Invading armies are often able to choose their ground and await an attack, since the enemy is obliged for the sake of national morale to defend the homeland. No better example of this compulsion could be found than the situation faced by Roman generals after Hannibal's crossing of the Alps into Italy (see HANNIBAL). One after another, they met him in headlong attack, only to go down to crushing defeat. Finally the proud republic was reduced to avoiding battle in order to recuperate.

Whenever the balance between offensive and defensive tactics is tipped too far in either direction, the social progress of the age is affected. In the 13th century the Mongol horsemen who overran Asia left desolation and anarchy in the wake of an irresistible offensive. Meanwhile, with fortification holding the advantage over siegecraft in Western Europe, the consequences of an all-powerful defensive were political and economic stagnation.

Until the 19th century, offensive and defensive cycles were of long duration. Improvements in weapons have come so rapidly since the Napoleonic era that the swing from one to another is a matter of only a few years. Generals of all armies were confident at the outbreak of World War I that the offensive power of the arms of 1914 would prevail in a few months. The machine gun had the leading part in turning the conflict into a stalemate, however, and not until the last few months of the war did the tank provide the victors with an offensive weapon capable of breaking the deadlock. Even so, a school of military thought held after the war that the defensive remained powerful enough to curb an aggressor in the next conflict. That illusion was soon dispelled when the German armies of 1940 drove on to a succession of early victories.

## I. TACTICS OF THE ANCIENT WORLD

**1. The Greek Phalanx.**—Two great tactical systems, the Greco-Macedonian and the Roman, dominated the ancient world (see ARMY). Citizen-soldiers of the Greek city-states fought in an eight-rank phalanx of heavy infantry supported by contingents of light foot. Although the *Iliad* mentions horse and chariots a millennium before the Christian era, cavalry was not an arm suited to a mountainous peninsula, and the incessant strife of the city-states was usually decided by the clash of opposing hedges of infantry spears.

Greek warfare was distinguished more for brawn and fortitude than the intellectual brilliance which made for greatness in other aspects of Greek life. Even the double envelopment which won the battle of Marathon (see fig. 1) for the Greeks in

FIG. 1.—BATTLE OF MARATHON (490 B.C.), SHOWING TACTICS OF CONCENTRIC ATTACK

490 B.C. seems to have been the product of a fortuitous event rather than generalship. Attacking at a fast pace, before the Persian superiority in cavalry and missile weapons could become effective, the Greek hoplites (heavily armed infantrymen) of both wings hurled back the lightly armed invaders in their path. Meanwhile, their own hard-pressed centre gave ground before the enemy advance until it seemed that defeat was imminent. As it proved, this withdrawal created the opportunity for the heavy infantry of the Greek wings to converge on the flanks and rear of the Persian host. Thus the battle ended with the demoralization and rout of an army which probably outnumbered the Greeks at least two to one.

**2. The Tactics of Epaminondas.**—Defending their homeland against the Persians, the Greeks learned to place increased reliance on cavalry and missile weapons—mercenary horsemen from the plains of Thessaly and bowmen from Crete. The first Greek to distinguish himself as a tactician was Epaminondas (q.v.) in 371 B.C. Facing a Spartan army of 10,000 men with a force of 4,000 which included undependable allies, the Theban commander drew up a strange oblique order of battle by advancing his left wing and reinforcing it with his best troops to a depth of 48 ranks (see fig. 2). On the other wing he placed his doubtful allies. The Battle of Leuctra opened with a cavalry clash won by the better-trained Theban horse. Then Epaminondas bore down with the infantry of his heavy left wing on the right of the Spartan phalanx, and the factor of surprise probably had more to do with the outcome than physical shock. At any rate, the Spartan right recoiled in disorder on its own centre, and a phalanx thrown into confusion was little better than a mob. The muscular tactics of Sparta were of no avail to demoralized men too crowded together to use hand weapons, and the Thebans gained a one-sided victory.

FIG. 2.—BATTLE OF LEUCTRA (371 B.C.), SHOWING TACTICS OF THE OBLIQUE ORDER

Epaminondas received a mortal wound while winning a second battle with his oblique order, and it remained for a barbarian prince to assemble the tactics of the disputatious Greeks into a system capable of conquering the world. Young Philip of Macedon was an attentive student of Epaminondas' methods while spending three years in Thebes as a hostage (see PHILIP II [of Macedonia]). He returned to his northern kingdom to organize the first army of ancient history to combine effectively such arms as infantry, cavalry, and artillery.

**3. The Greco-Macedonian Tactical System.**—The new tactical system was built about the phalanx. Philip strengthened the mobile human fortress by doubling the eight-rank formation of the Greeks and arming his warriors with a longer and heavier spear. He perceived that the two chief weaknesses of the phalanx were the vulnerability of its flanks and the inability to maneuver or even retain its solidarity on rough ground. As a tactical remedy for both defects, he organized and trained a light infantry such as the ancient world had never known before—a disciplined force of archers, slingers, and javelin men. Their function was to act as tactical hinges on both sides of the phalanx, lending mobility as well as protection. Since the young nobles of Macedonia preferred to fight on horseback, Philip had no difficulty in organizing a heavy cavalry arm far superior to the establishments of the Greek city-states. Squadrons of light horse were also employed for scouting and skirmishing.

That the army had an efficient baggage train, medical corps, and engineering section is evident from its accomplishments. In his development of "artillery," moreover, the Macedonian king went far beyond his predecessors who had found war engines useful only for siegecraft (see ENGINES OF WAR). He originated the idea of carrying only the essential parts on the march and depending on his engineers to cut timbers for the framework whenever needed.

On the battlefield the full phalanx of about 8,000 heavily armoured spearmen was doubtless a fearsome spectacle as it advanced with menacing steel points. Several such bodies of troops

might be employed as the central bulwark of the battle line, the pivot either of offense or defense. On the wings were the heavy cavalry squadrons trained for shock effect. Between the phalangial centre and cavalry wings, the tactical hinges of light foot supplied the flexibility for maneuver.

**4. World Conquest.**—This was the army which Philip led to the conquest of Greece and his son Alexander made the instrument of world conquest. The Greco-Macedonian tactical system met its greatest battlefield test on the field of Arbela, or Gaugamela, in 331 B.C. Darius III, the Persian monarch, had a numerical advantage of perhaps five to one over Alexander's 7,000 cavalry and 40,000 foot. The action took place near the ruins of ancient Nineveh on a plain suited to the Persian cavalry and chariots (see fig. 3). Despite the odds against him, Alexander rejected the plan of a night attack urged by his nobles. He opened the battle by seizing the initiative with a rapid advance of his right wing, followed in echelon by the rest of the army. The local superiority in numbers enabled him

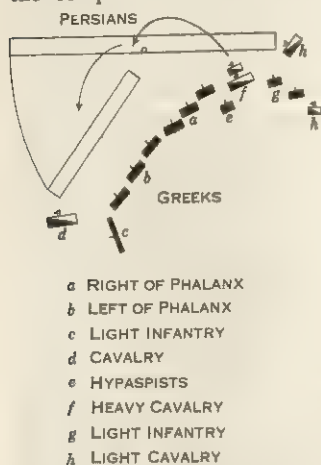

FIG. 3.—BATTLE OF ARBELA, OR GAUGAMELA, (331 B.C.), SHOWING TACTICS OF REAR ATTACK

to drive so deeply between the enemy's left and centre as to reach the rear. A more perfect example of the battle of penetration can scarcely be found in the pages of history, for the Persian host was routed while still possessing a great numerical superiority.

Alexander's campaigns took him as far as modern India and Afghanistan during the six years after his conquest of Persia. Among his most troublesome foes were the Scythian horsemen who preyed upon his flanks and rear, seeking to cut off detachments. That the nomadic riders of the Asian plains could be formidable opponents was demonstrated in later centuries when no less than four Roman armies were lured to their destruction.

The Scythians and Parthians were made natural warriors by a harsh environment. Shunning action at close quarters, fleeing when pressed, then returning to the attack in swirling envelopments, they could discharge arrows while riding at top speed.

Alexander refused to be drawn into extended pursuits by feigned flights. Noting that the indiscipline of the Scythians made them reckless at times, he trained his light infantry to launch surprise counterattacks and beat the nomads at their own game by cutting off detachments. Once the lightly armed Scythians were at close quarters, they were no match for Alexander's cavalry.

**5. The Rise of Rome.**—The conqueror's death was followed by the rapid crumbling of the great empire he had founded. But while his former generals disputed for mastery, a young and vigorous war power was rising in the west. Fighting in a simple phalanx of heavy infantry at first, the Romans learned by defeat that the human wall is not suited to battle on rough ground.

The new tactical system which gradually evolved was the legion (see fig. 4). Under the republic it consisted of small and supple infantry units known as maniples, each numbering 120 men in 12 files and 10 ranks. In a typical battle order the first two lines, drawn up in chessboard array, were composed of 10 maniples each. An interval equal to a maniple's front of 60 ft. separated the units, enabling the second line to merge with the first or the first to fall back into the second. The advantages of mobility could thus be exchanged for those of solidarity, since the two lines combined had a depth of ten ranks and a front of 1,200 ft.

FIG. 4.—LEGION IN BATTLE ORDER: FIRST TWO LINES, HEAVY INFANTRY; THIRD LINE, CAVALRY AND LIGHT INFANTRY ALTERNATED WITH RESERVES

In the third line ten units of light foot were alternated with a like number of reserve units, the former numbering 120 men each and the latter 60. The three lines were 250 ft. apart, and from front to rear one maniple of each classification formed a cohort. This was the Roman equivalent of a battalion, numbering 420 men. Ten cohorts made up the infantry strength of a legion but 20 were customarily combined with a small cavalry force and other supporting units into a self-sustaining little army of about 10,000 men.

The two famous Roman infantry weapons were the *pilum* and *gladius*—the first a 7-ft. javelin used for both throwing and thrusting, and the latter a 20-in. cut-and-thrust sword with a broad, heavy blade. For protection the legionary had a metal helmet, cuirass, and convex shield, but aggressive action was deemed a Roman's best defense. The first line attacked on the double, hurling javelins and diving in with swords before the enemy had time to recover. Then came the maniples of the second line, and only a resolute foe could rally from the two successive shocks.

**6. The Battle of Cannae.**—When Hannibal descended from the Alps in 218 B.C. with an army of Iberian, Numidian, and Gallic mercenaries, the republic paid the penalty of placing too much reliance on heavy infantry and failing to develop a cavalry arm and missile weapons. Two Roman armies, destroyed in the early encounters, were outmaneuvered and cut to pieces by the Carthaginian horse. Finally, Rome incurred a disaster which has made the name of Cannae a symbol ever since of the battle of annihilation and double envelopment (see fig. 5).

FIG. 5.—BATTLE OF CANNAE (216 B.C.), SHOWING TACTICS OF DOUBLE ENVELOPMENT

Hannibal provoked an action, though much outnumbered by a Roman army of 85,000 men. Adopting a convex formation of his foot in the centre, he gradually withdrew it in a feigned retreat until the Roman infantry rushed in recklessly, raising the victory shout. When the converging legionaries were too crowded together to use their weapons, the Carthaginian closed the trap by assailing the flanks and rear of the Roman infantry with his cavalry after driving the inferior enemy horse from the field. The result was a prolonged slaughter of helpless men which lasted until only about 15,000 scattered fugitives survived Rome's greatest disaster.

The victor managed to maintain himself for 16 years in a hostile country before the republic developed in Scipio Africanus a general who understood that a tactical system based on a single arm is as handicapped as a one-armed man would be in personal combat. He carried the war to Carthaginian territory in Spain and finally invaded Carthage. Hannibal returned in the autumn of 203 B.C. to defend his own country but was defeated on the field of Zama (202 B.C.) by the superior Roman cavalry.

**7. Tactics of the Cohorts.**—The patriotic citizen-soldier of the republic's early years was replaced during the century of civil war by a professional soldiery serving for pay and donatives. The cohort of an average field strength of 360 men gradually replaced the maniple as the tactical unit of increasingly larger Roman armies. Ten cohorts made up a legion in the operations of Sulla and Caesar. The 3,600 heavy infantry were supported by enough horse and light infantry to bring the numbers up to 6,000 in all.

The maniple survived only as a unit of a cohort of eight or ten ranks. Four cohorts in the first line and three each in the second and third lines were drawn up in chessboard array, with intervals between units so that one line could merge with another (see fig. 6). Seven legions in three lines, comprising about 25,000 heavy infantry, occupied a mile and a half of front. This was an average of about 11 men to a metre of front as compared to 28 in Alexander's army.

The practical good sense which distinguished Roman tactics was at its best in field fortification. No greater demonstration was ever seen in the ancient world than the 50 mi. of works with which Caesar gained the submission of Vercingetorix and 80,000 Gauls at Alesia. The Romans began by surrounding the strong natural

defenses with a system of walls and trenches. When Gallic allies marched to the rescue of his opponent, Caesar surrounded his own army with works of circumvallation and beat off foes both in front and rear. Finally the relieving army disintegrated and Vercingetorix was starved into surrender.

**8. Tactics of the Empire.**—A gradual change in tactics was evident as Rome evolved from a conquering into a defending power. The spade and axe continued to be effective weapons of a cordon defense established along the frontiers, utilizing such natural barriers as the Rhine and Danube. Where they were lacking, the Romans built such works as the great walls in Britain and the wooden palisades (*limes*) of Germany.

The cohort, increased to a field strength of 500 to 600 men, remained the unit of tactics which still trusted to the shock of *pilum* and *gladius*. But the 5,000 to 6,000 heavy infantry of the legion were combined with an equal number of supporting troops—cavalry, both heavy and light, and a light infantry made up of archers, slingers, and javelin men.

During the first two centuries of the empire the proportion of mounted troops rose from one-seventh to one-fourth as the legion dealt with mounted barbarian raiders. Where war engines had been used chiefly in siegecraft, the empire relied upon them for the defense of fortified border outposts. By the 4th century A.D. according to Vegetius, as many as 10 catapults and 60 ballistas were assigned to each legion—a ratio of a “gun” or “howitzer” to 1,000 infantry. This is a higher proportion than the average of three pieces of artillery to 1,000 men in Napoleon’s armies.

## II. THE CAVALRY CYCLE

**1. The Byzantine Horse-Archer.**—After the fall of Rome the Eastern or Byzantine Empire managed to survive by means of bribing the most formidable barbarians and inducing them to move on to the occupation of Italy. The respite enabled Constantinople to develop during the reign of Justinian (A.D. 527–565) a cavalry tactical system which won victories on three continents.

This system was built about the horse-archer. The invention of the stirrup in the 6th century had given an impetus to cavalry warfare, and the historian Procopius has described the tactics of the mounted mercenaries whom Belisarius led to conquests in Persia, North Africa, and Italy.

“But the horsemen of the present time go into battle wearing corselets and fitted out with greaves which extend up to the knee. From the right side hang their arrows, from the other the sword. And there are some who have a spear also attached to them and, at the shoulders, a sort of small shield without a grip, such as to cover the region of the face and neck. They are expert horsemen, and are able without difficulty to direct their bows to either side while riding at full speed, and to shoot an opponent whether in pursuit or flight. They draw the bowstring along by the forehead about opposite the right ear, thereby charging an arrow with such impetus as to kill whoever stands in the way, shield and corselet alike having no power to check its force. Still, there are those who take into consideration none of these things, who reverence and worship the ancient times, and give no credit to modern improvements.” (Procopius, *Works*, trans. by H. B. Dewing [Loeb Classical Library], vol. i, p. 7, Harvard University Press, Cambridge, Mass., 1914.)

Belisarius, landing in North Africa with 15,000 men, made easy work of the kingdom founded by the Vandals on the site of ancient Carthage. When he defeated the Ostrogoths in Italy and took Rome, another king was sent as a prisoner to join the captive Vandal monarch at Constantinople. It appeared for a time that Justinian’s generals were about to restore the ancient grandeur of Rome, but the conquests were soon lost by an eastern empire exposed to the onslaughts of Slav, Avar, Bulgarian, Persian, Saracen, Frank, Russian, and Turk during five centuries of continual warfare.

FIG. 8.—LEGION IN BATTLE ORDER: FOUR COHORTS IN THE FIRST LINE AND THREE EACH IN THE SECOND AND THIRD LINES WITH CAVALRY

**2. The Byzantine Tactical System.**—Byzantine tactics were eminently practical, the spirit of chivalry being unknown in an empire constantly fighting for existence. Greek in speech as well as tradition, Constantinople reduced war to a science with a series of treatises and manuals. The *Tactica* of Emperor Leo the Wise, written about 900, urged that operations should be varied to take advantage of each foe’s peculiar weaknesses. Fraud and feigned flights were suggested without apology. If a foe could be bribed more cheaply than defeated, eastern Roman emperors deemed it no disgrace to pay tribute.

Since most of Constantinople’s foes were mounted, the tactical system placed the emphasis on heavy cavalry, both archers and lancers. But even though the infantry ranked as a secondary arm, it was well-trained and combined with mounted troops in proportions suited to tactical demands. Squadrons of light horse were employed for scouting and reconnaissance.

Byzantine armies stood between the West and Asian invaders at a time when the impoverished Europe of the Dark Ages would probably have been overrun. Charles Martel and his Franks had difficulty in repulsing a single large-scale Moorish plunder raid on the field of Tours in 732. Yet Constantinople held its own in an 83-year war with the Saracens when Islam was at the height of its conquering momentum.

At the outset the Muslims were cavalry warriors using much the same tactics as the Parthians and Scythians. Where they differed from other plains horsemen was in the ability to learn from their foes. After experience taught the need, the Saracens organized a heavy cavalry of their own and adopted many of the East-Roman tactics. Most astonishing of all, these former desert dwellers took to the sea and built ships large enough to launch two great land and water invasions which were repulsed outside the walls of Constantinople. Only that secret Byzantine weapon known as Greek fire (*q.v.*) saved the imperial city in 673.

**3. Tactics of the Franks.**—It was fortunate that Europe was spared a severe test, for as late as the 8th century the Franks could raise only masses of untrained and largely unarmoured men using the most primitive tactics. Even after Charlemagne introduced strenuous military reforms, he was not able until the final edict of his long reign (771–814) to forbid any man appearing for duty when armed only with a club.

The low esteem in which the Franks were held by skilled warriors is evident from Leo’s *Tactica*. Admitting that the headlong charge of mounted Franks with lance and broadsword could be formidable, he advised that “it is best to decline a pitched battle with them until you have put all the chances on your side. You should take advantage of their indiscipline and disorder; whether fighting on foot or on horseback, they charge in dense, unwieldy masses which cannot manoeuvre because they have neither organization nor drill. . . . Hence they fall readily into confusion if suddenly attacked in front and rear—a thing easy to accomplish, since they are utterly careless and neglect the use of pickets and vedettes.” (C. W. C. Oman, *A History of the Art of War in the Middle Ages*, vol. ii, p. 204. By permission of Methuen & Co., Ltd., London, 1924.)

Charlemagne made an unceasing effort to create a disciplined army of mailed cavalry out of the Frankish host of unarmoured foot. Ownership of land was the basis of military duty. Proprietors of large estates were commanded to send a mounted warrior equipped with a mail shirt, while masters of smaller tracts must at least combine to arm a man with spear and shield. Thus came into being the feudal system which was to shape the warfare of Europe during the next several centuries.

Despite the emperor’s reforms, Europe was long helpless against the plunder raids of the Vikings. Both the Greeks and Romans had depended on marines trained for shipboard duty and amphibious combat landings, and Constantinople had carried on the tradition. The Norsemen in their turn were unsurpassed as amphibious warriors. Their single-deck ships with carved prows and shield-hung bulwarks were fast and seaworthy, and experience had taught them effective tactics of seizing a beachhead after pushing up such rivers as the Loire and Meuse. The Vikings were formidable fighting men with axe and sword, and their forays grew

so bold during the last half of the 9th century that they sacked London and laid siege to Paris.

There was not time to summon large armed forces from a distance against these fleet raiders. Each district had to fend for itself and the feudal system burgeoned as Europeans paid military duty to the local lord upon whom they relied for protection. Cavalry tactics were also given another impetus, for only mailed horsemen could cope with the Norsemen. Seldom has the social progress of an age been so largely shaped by tactical factors.

**4. The Decline of Infantry.**—In 1066, at the Battle of Hastings, the last infantry host of Western Europe went down to defeat in England before the descendants of Norsemen who had settled in France and learned to fight on horseback. The mounted and armoured men-at-arms had become virtually the tactical unit of artless battles which had as their first object the seizing of opponents to hold for ransom. Serfs who fought on foot were held in such low esteem that no count was taken of their numbers or losses.

Except for a few crossbowmen, Europe's armies of the crusades had no infantry worthy of the name. A similar situation prevailed in Asia, where the Mongols led by Genghis Khan built up a formidable cavalry system. The bow, lance, and scimitar were the weapons of fierce horsemen who used two varieties of bows and three "calibres" of arrows for various tactical purposes. The Great Wall of China, with its 1,500 mi. of earth-filled brick or granite, proved to be no serious obstacle to invaders who swept like a pestilence from the Yangtze to the Vistula during the 13th century without incurring a single major defeat. Whether the conquerors could have continued to win victories in the mountains and forests of Western Europe is open to speculation, for they returned to Asia after defeating the feudal horsemen of Hungary and Poland.

**5. Medieval Tactics of Europe.**—In contrast to the supremacy of the offensive in Asia, the defensive was all-powerful in medieval Europe. Concentric fortification added to the difficulties of besiegers by making it necessary to attack walls within walls as well as outer wards and foreworks, while the crossbow provided the garrison with a means of enfilade fire from rounded keeps. Meanwhile, the gradual transition from chain to plate armour made the mailed knight and his barded charger more invulnerable to the weapons of the day (*see further* ARMOUR, BODY).

The wretched communications of medieval Europe were a deterrent to maneuver even if the unruly armed forces of the 13th century had been disciplined enough to attempt it. It was seldom possible to force a battle on an unwilling opponent, and methods of supply were so primitive that an army often had to abandon a half-finished campaign after eating a province bare.

That the tactical superiority of the knight owed a great deal to his monopoly of the prerogative of bearing arms was demonstrated by despoiled Flemish burghers at the battle of Courtrai in 1302. French men-at-arms, putting down a revolt, launched their usual thundering charge only to bog down in disorder upon reaching marshy ground they had not troubled to reconnoitre. The Flemish foot clubbed the knights out of the saddle and dispatched them as they lay helpless in the mud, too burdened with armour to defend themselves.

**6. Longbow and Halberd.**—The use of gunpowder in the 13th century made it inevitable that the supremacy of the man of iron in his house of stone could not be long maintained. But the first handguns were not as effective as either the crossbow or English longbow, and it was actually the rise of disciplined forces of yeomen using infantry tactics which restored the balance between the offensive and defensive in medieval Europe.

Although a few weapons using gunpowder were present on the field of Crécy (*q.v.*) in 1346, the outcome owed more to the discipline and tactics of an English army in which every man received a fixed and regular wage. For it was truly a national army that Edward III led to France, and the French knights would probably have been defeated even if the invaders had been armed with a less effective weapon than the 6-ft. longbow. Its superiority over the crossbow of the Genoese mercenaries was proved in a preliminary exchange of missiles. Edward had placed his dismounted men-at-arms in the centre as spearmen, and on both

projecting wings the lightly armoured archers stood behind ditches and pointed stakes. They poured deadly flights of arrows into the front and flanks of the advancing French knights until 16 successive charges had been repulsed with heavy losses.

Another infantry tactical system was winning victories meanwhile in Central Europe at the expense of the Austrian knights. Swiss burghers and peasants, fighting for their liberties, depended on a medieval phalanx composed of spearmen and warriors armed with the halberd—an 8-ft. shaft which had the blade of an axe, the point of a spear, and a hook for pulling a rider out of the saddle.

The Swiss phalanx of the 15th century consisted of three-fifths halberds, one-fifth spears, and one-fifth missile weapons, chiefly crossbows with handguns slowly gaining in favour. In the interests of mobility the men of the cantons discarded all armour except the helmet and cuirass. Marching 30 mi. a day to meet the enemy, they attacked with a celerity and discipline which were disconcerting to medieval adversaries. If hard-pressed, the Swiss "formed the hedgehog" by facing outward in all directions as men from the rear ranks filled any gap in front.

**7. Early Victories of Gunpowder.**—After beating mailed horsemen who had resisted tactical change, the English and Swiss in their turn were defeated because they lagged behind the military progress of the age. It had taken weapons of gunpowder a century and a half to have much influence on tactics, but at the siege of Orléans in 1428–1429 both sides used cannon firing stone balls. The French guns were better served than the mortars and bombards brought by the English, who met defeat at the battle of Patay after abandoning the siege.

Charles VII of France raised the first standing army of the Middle Ages—9,000 permanent troops, paid and armed by the king. This force gradually won back the French territory conquered by the English in the Hundred Years' War, and at the Battle of Formigny in 1450 the invaders were decisively beaten after making their customary defensive stand with the longbowmen on both wings. Instead of launching their usual charge the outnumbered French brought up culverins, or medieval field-pieces, and cut the English archers to pieces with enfilade fire. The Swiss phalanx was granted a longer period of grace, but eventually it too was to pay with defeat for clinging obstinately to outworn tactics.

Of all the early exponents of gunpowder weapons, perhaps the most remarkable was Jan Žižka's army of Bohemian peasants. Several crusades were proclaimed by Pope Martin V against these dissenting followers of John Huss, but the German and Hungarian knights encountered the most advanced tactical system of the new age of gunpowder. Combining the strategic offensive with the tactical defensive, the Hussite military genius drew up a line of "wagonforts"—armoured wagons affording cover to infantry armed with both handguns and crossbows. Between the vehicles were cannon mounted on four-wheeled carts and protected by infantry with pikes. Behind both wings the cavalry waited in readiness to deliver a counterstroke or lead a pursuit.

The combination of the three arms continued to prevail without a single reverse after the death of the blind leader. More than 50 battles and combats were won by the Hussites in 14 years, but civil war led to the destruction of armies which had been invincible against the invading knights.

### III. THE MILITARY RENAISSANCE

**1. The Fall of Constantinople.**—In 1453 it was evident that a new military age had dawned when the Turks breached the walls of Constantinople with a siege train of 70 cannon. After 40 days of bombardment enough towers had been leveled and holes opened in the masonry for a general land and sea assault to succeed.

If weapons of gunpowder could batter down the strongest walls of Europe, it was plain that a defensive based on iron men in stone castles was no longer dominant. By the middle of the 15th century the plate armour panoply had become so heavy that special breeds of horses, the ancestors of Percherons and Belgians, were reared as chargers. Only armour of prohibitive weight could stop a ball from a handgun at close range, and men were beginning to

suspect that mobility offered more protection than iron.

Fortification (*q.v.*) and siegecraft had changed but little in 2,000 years. Down to the 14th century an Assyrian of 700 B.C. would not have found much to astonish him in the attack and defense of walled strongholds in Europe. But after the fall of Constantinople it was realized that the wall was obsolescent. Works of the future must be low and screened, burrowing into the earth for security. Besiegers must dig their way forward in a maze of parallels and approaches affording shelter from the fire of the besieged.

About this time the ponderous handgun was being superseded by the arquebus—a comparatively portable matchlock which could be fired from the shoulder. Improvements in the manufacture of wheeled cannon had resulted in slender guns of cast iron or bronze firing iron balls. The principle of the limber had been discovered thus increasing mobility, and the invention of the trunnion permitted the muzzle to be elevated or depressed for more accurate aim. (See ARTILLERY; SMALL ARMS, MILITARY.)

The new weapons were utilized by brilliant captains in the struggle between France and Spain for control of Italy early in the 16th century. Tactical values changed from one battle to another with bewildering rapidity. On the field of Cerignola in 1503 the French infantry and Swiss mercenary pikemen were mowed down by the fire of Spanish arquebusiers who counterattacked and captured the enemy's entire artillery train. Nine years later, at the battle of Ravenna, the Spaniards again put their trust in entrenched arquebusiers. But this time the French moved 24 cannon to the enemy's flank and surprised the Spanish infantry with a deadly enfilade fire which decided one of the bloodiest battles of the age.

Again in 1515 the French artillery upheld its reputation by putting an end to the Swiss legend of invincibility. After winning their independence the men of the cantons had become the competitors of the German *Landsknechte* as Europe's leading mercenaries. And though the Swiss had increased the proportion of firearms in their phalanx, they still depended mainly on the "push of pike" for victory. In the Battle of Marignano, as Spanish hirelings, they paid the penalty of obsolescent tactics when the French repulsed 30 charges by blasting holes in the Swiss ranks with cannon and launching cavalry counterattacks.

Ten years later, on the field of Pavia, the French artillery seemed on the way to another triumph. At the critical moment, however, the victory was won by a surprise advance of 1,500 Spanish arquebusiers. Taking cover behind walls and hedges to fire at will, these elusive marksmen cut down *Landsknechte* who had no opportunity to use their pikes.

**2. Pike and Arquebus.**—Not only had the Spaniards won Italy; they had also founded a new school of infantry tactics which was to rule the battlefields of Europe for a century and make incredibly daring conquests in the New World. Although the battle of Pavia had been won as much by mobility as firepower, the agile combat groups of that victory were gradually replaced by the first phalanx of the age of gunpowder—solid columns of infantry known as battles. Various combinations of "shot and pike" were used, but usually the arquebusiers were drawn up on the corners of battles 25 ranks deep. After firing at the word of command, each rank withdrew to the rear to reload and gradually moved forward by successive volleys until its turn came again. It was the function of the pikes to protect the arquebusiers while reloading. When the enemy's ranks were broken by firepower, the pikemen evolved from square into line and advanced, shoulder to shoulder, in a massive charge calculated to sweep the field (see fig. 7).

The *tercio* of about 3,000 foot was the basic Spanish tactical unit. Consisting of 12 companies of about 250 men each, the fighting strength in 1534 was divided equally between pikemen and arquebusiers. Cavalry was represented in one-twelfth of infantry strength, and artillery by an average of one gun to each 1,000 foot.

The value of tactics and discipline was illustrated during the reign of the emperor Charles V (*q.v.*) when small bands of Spaniards won amazing victories over hordes in Mexico, Peru, and the islands of the Caribbean. The natives were not wanting in sacrificial courage, and their advantage in numbers compensated for

FIG. 7.—EVOLUTION OF THE SQUARE INTO THE LINE

inferiority in weapons. One Aztec might have been a match for a Spaniard in single combat, but a thousand Aztecs were routed by a hundred Spaniards because they lacked the tenacity instilled by discipline as well as tactical system and precision.

**3. Maurice of Nassau.**—Tactical history repeated itself when the Dutch fighting for independence organized the first cohorts of the age of gunpowder to oppose the first phalanx. The Spanish forces had won the early battles of the Netherlands revolt with ease over larger armies of Dutch students, rustics, and burghers. Defeat taught the harsh lesson that patriotism was not enough, and Maurice (*q.v.*) of Nassau (prince of Orange) trained a dependable Dutch standing army. Since the Spanish battles were unwieldy in maneuver, he revived Roman mobility by forming infantry regiments of 800 to 1,000 men, consisting of ten companies of pikemen and musketeers in equal numbers.

During the Wars of Religion the arquebus had been replaced by the musket, which was simply a heavier and more effective matchlock. Accuracy was increased by the introduction of a portable iron fork serving as a rest when the soldier took aim, though it was still necessary to protect him with pikes while reloading.

Another 16th-century invention, the wheel-lock pistol, caused a revival of cavalry tactics. Fired by a steel-toothed wheel which struck sparks from pyrites after the release of a tightly wound spring, the new pistol led to the cavalry tactic known as the caracole, designed to harass squares of pikemen. Advancing in successive waves, the horsemen fired their wheel locks in the faces of the enemy, then swerved off to the rear to reload.

The war in the Netherlands was decided chiefly by siegecraft and fortification. But at Nieuwpoort in 1600 the mobile Dutch cohorts defeated the Spanish phalanx in a battle fought among sea-side dunes. Maurice's companies, drawn up in chessboard array, had a great advantage in maneuver over the three Spanish battalions of about 3,000 men each. The Dutch prince used heavy artillery to open the action and brought up fieldpieces to accompany his infantry and give close support. When the Spanish squares broke, Maurice's small but well-trained cavalry led the pursuit.

**4. Gustavus Adolphus and the Thirty Years' War.**—It remained for Gustavus Adolphus (*q.v.*) to improve upon Dutch reforms and merit the title, "father of modern tactics." The Swedish king organized his infantry into brigades, each consisting of two regiments which in turn included two battalions. Each battalion of 1,000 men was divided into eight companies of an average strength of 75 muskets and 60 pikes.

Swedish armourers had developed a lighter musket and Gustavus is credited with being first to introduce paper cartridges to speed reloading. On the firing line his six ranks advanced in open order and closed up into three, the first rank kneeling and the other two standing while firing a volley.

The Swedish artillery also benefited from innovations. Advances in metallurgy having made possible a lighter fieldpiece, Gustavus recalled most of his old ordnance. It was recast into four-pounders of 3 ft. 10 in. in length, 400 lb. in weight, and 2.6 in. calibre. Four men or a single horse could handle the new gun on the field, though the four-pounders of other armies weighed half a ton or more.

The first artillery cartridge was developed as ammunition—a thin wooden case holding a prepared powder charge wired to the ball. Improvements were also made in the "bomb" or shell—a hollow iron sphere filled with gunpowder and fired with a lighted fuze. Reloading was speeded to such an extent that the Swedish four-pounder could be discharged eight times while the best musketeers fired six volleys. This was the first regimental piece of history, and each Swedish regiment of 1,000 men brought two four-pounders into the field.

It was characteristic of the forthright Swedish king to replace caracole tactics by training his cavalry entirely for shock effect

with pistol and sabre. As light cavalry he organized Europe's first regular dragoon corps—a tactical hybrid made up of men armed with carbine and sabre who could fight either in the saddle or on foot.

The decline in body armour was accelerated when Gustavus himself discarded all protection save a leather buff coat. Field fortification was also reduced to its simplest elements by an army priding itself on the boast, "The Swedes do not defend their men with walls; the Swedes defend their walls with men."

In the Battle of Breitenfeld (1631), the first large-scale test, Gustavus opened the action by committing 100 cannon to a long-distance artillery "preparation." Then his self-sustained battalions, each a mobile combat group of pikemen and musketeers with their own four-pounder, were able by virtue of rapid shifts to concentrate fire where it was most effective (see fig. 8). Of the

33,000 imperial troops, 7,000 were captured and 12,000 killed or wounded. Only about 2,000 survivors could be rallied after the pursuit.

Although Gustavus inflicted another defeat on the imperialists in the Battle of Lützen the following year, he paid with his life. In two years of campaigning he had overrun Germany, but after his death the army soon degenerated into another of the plundering hosts which made the war one of the most destructive of history.

#### IV. THE AGE OF LINEAR TACTICS

**1. The New Age of Moderation.**—It has aptly been said that the tactics which end one war are those which will begin the next. After the bloody battles of the Thirty Years' War resulted in a prolonged stalemate, the vicomte de Turenne (*q.v.*), commanding mercenaries paid by France, cleared the enemy from Bavaria in a campaign of maneuver, compelling the king to sue for an armistice. Avoiding battle unless he had an overwhelming advantage, the French tactician relied upon caution, precision, and surprise to drive the enemy into ravaged areas while retaining his own sources of supply.

Thus the savage excesses of the war were made to appear futile by tactics which foreshadowed the most moderate era of strife in modern history. The founding father of the new military age was the marquis de Louvois (1639–91), minister of war at the court of Louis XIV of France. Recognizing that tactics are dependent on supply, he organized a quartermaster general's department and a trained commissariat. As fixed points of maneuver, he established magazines at strategic centres for storage of reserves of food, ammunition, and equipment. The French minister also foresaw that two recent improvements in weapons would lead to tactical change. The first was the socket bayonet, which superseded the pike by providing every musketeer with his own means of protection. Equally important was the invention of the flintlock musket, making it possible to dispense with the clumsy lengths of smoldering "match."

Even Gustavus had not been able to reduce the depth of his formations to fewer than six ranks. But now that it was no longer necessary to combine pikes with muskets, Louvois perceived that the day of linear warfare had dawned. His famous drillmaster, Gen. Jean Martinet, whose name has lived as a byword, trained the troops of the new French armies to deploy from column into line and advance in three ranks, pausing to fire platoon volleys at the word of command. The effect depended on precision of approach, and the men were trained to move forward in unison, keeping step at a stately cadence of 80 paces a minute.

Although the volunteer system prevailed in theory, the soldiers of the new military era were actually recruited for the most part by force, fraud, or various forms of legalized blackmail. Since it took from three to five years to train a man for linear tactics, Louvois made a study of morale with a view to reducing the high ratio of desertions prevailing in the Thirty Years' War. The French army became the first to be completely uniformed, and the war minister was a pioneer in the awarding of medals for valor. He set another tradition with his annual war games in which large bodies of troops were trained to maneuver under simulated combat conditions.

**2. The Wars of Louis XIV.**—The French army had no equal in numbers as well as quality when Louis XIV began the aggressions which were to involve him in wars throughout his long reign. But the battle of Seneffe in 1674 made it plain that grievous losses were to be expected by the best troops when opposing lines traded volleys at 50 paces as a prelude to charging with the bayonet. Only iron discipline could fit men to stand firm and fill the gaps in the ranks, for the death casualties alone in this clash amounted to 17% for both armies.

Large-scale actions depended virtually on mutual consent, since a general could refuse by withdrawing to country too hilly or wooded for the precision demanded by linear tactics. As all armies adopted the magazine system, fortification and siegecraft became more decisive than battle, and some thrifty victories were won by Sébastien le Prestre de Vauban (*q.v.*) in attacks on enemy strongholds. He prevailed on Louvois to increase the number of mortars and organize battalions of troops armed with grenades. It became the military fashion to select only the tallest men for this dangerous duty, so that the grenadiers were recognized as the elite of the infantry.

**3. The Tactical Theories of Marshal Saxe.**—Pillage and devastation were reduced to a minimum by disciplined armies of long-term troops. Payment was made for supplies even in enemy territory, and generals sought to gain their ends by maneuver rather than hard fighting. "I am not in favor of giving battle," declared Marshal Maurice de Saxe (*q.v.*), who won a memorable victory over an English and Dutch army at Fontenoy in 1745. "I am even convinced that a general can wage war all his life without being compelled to do so." Saxe foresaw the need for a trained light infantry and managed to raise companies for his Netherlands campaigns in the War of the Austrian Succession (*q.v.*). His victory at Fontenoy was made possible by redoubts from which his troops poured a deadly enfilade fire into their assailants. He also experimented with the unit which became the tactical ancestor of the division. Two brigades of infantry and one of cavalry were combined with artillery into a unit intended to be tactically self-sufficient in local operations, yet capable of concentrating with like units for battle.

**4. Frederick the Great.**—Saxe's theories might have found widespread adoption sooner if they had not been eclipsed by the dramatic victories of Frederick the Great (*q.v.*). On the field of Leuthen in 1757, Frederick won one of history's most famous victories by defeating an Austrian army of 72,000 troops with 43,000 Prussians. As a tactical innovation, Frederick brought up a battery of ten fortress guns to support his infantry battalions, each of which dragged a six-pounder to supplement the heaviest concentration of artillery ever seen on a European battlefield up to that time. The blue-clad Prussian infantry advanced in staggered alignment, so that the left was refused while the heavily reinforced right bore down on Austrians outnumbered at the point of contact. This was the "oblique order" which won fame for Frederick, though it was nothing more mysterious than a well-timed and executed flank attack which collected a victory already half-won by the fortress guns and six-pounders.

Frederick's greatest contributions to tactics, in fact, were in artillery. Regimental pieces had previously been drawn into battle by soldiers tugging at ropes, but Frederick blamed his crushing defeat in the Battle of Kunersdorf on lack of artillery mobility. As a remedy, he ordered that four horses in file be hitched to each piece, making it possible to bring larger quantities of ammunition into the field. He also placed more emphasis on how-

their fire in battle than predecessors who had regarded this type of cannon as being merely a weapon of siegecraft.

## V. NAPOLEON AND 19TH-CENTURY TACTICS

**1. The American Revolution.**—Many of the tactics of the Napoleonic era had their roots in the American Revolution (*q.v.*). Lafayette and two of Napoleon's future marshals, Jean Baptiste Jourdan and Louis Alexandre Berthier, returned from service in that war with glowing accounts of new light infantry tactics. On the British side, Sir John Moore (*q.v.*), who was to shape the tactics of Wellington's armies, participated as a youthful subaltern. It was evident to these observers that the American frontier rifle ranked as history's first infantry firearm of precision. Although it took twice as long as a smoothbore musket to reload, it had from two to three times the effective range in addition to an accuracy which was beyond comparison.

Although a majority of the Americans carried smoothbore muskets, the farmers and villagers of the New World were accustomed to hunting small game at a time when laws against poaching and possessing firearms prevailed in Europe. The greenest American recruits took aim instinctively while European regulars were trained to point the piece in the general direction of the foe and fire at the word of command. Thus at the Battle of Bunker Hill (*q.v.*) most of the British shots passed harmlessly over the heads of Americans who inflicted casualties of 45% with their limited ammunition by taking "aim at the handsome waistcoats." Because of the broken country, light infantry tactics flourished in the American Revolution. And since all the armies were small, a two-rank line gained approval as a means of adding to infantry firepower.

**2. French Revolutionary Tactics.**—The "horde tactics" of the French revolutionary armies evolved from military poverty. Lacking magazines, the *sans-culottes* gained in mobility by becoming less dependent on bases and lines of communication. Lacking tents, they learned to bivouac in the field, where all units could be more swiftly concentrated. Lacking supply wagons, they learned to march at a more rapid cadence than their opponents. Lacking training for the precision of linear tactics, they gradually developed a more effective attack of their own.

Lafayette had urged that a rifle company be included in each battalion of the revolutionary forces, and Jourdan tried to instruct his troops in light infantry tactics. Not much came of these efforts, but at least two lessons of the American conflict were put into effect—fire at will, as distinguished from volley fire, and taking natural cover on the skirmish line. Upon coming in contact with the enemy, the bolder spirits of a revolutionary army swarmed out to fire from ditches or behind hedges. The platoon volleys of linear tactics were not effective against these elusive French skirmishers, who took to their heels when threatened with a bayonet charge. Fighting of this sort was so interesting and comparatively safe that more and more men participated. Finally, at the Battle of Hondschoote in 1793, General Jourdan's forces concentrated swiftly and almost literally mobbed an allied rear guard detachment with a wild bayonet attack.

Fortunately for the *sans-culottes*, the royal artillery and engineers, as technical branches, had never attracted the nobility. Many of the officers adopted the cause of the Revolution, and by 1793 the French were able to open a battle with a respectable cannonading while the skirmishers were peppering the enemy with harassing fire. Skill and confidence came with experience until the revolutionary masses of attack bore more resemblance to columns and less to rioting mobs. The allies found it disconcerting, moreover, when a French army doubled in size within a few hours as distant units hastened to the battlefield at the quick-step from all sides.

**3. Bonaparte's Early Victories.**—It is taking no credit away from Bonaparte's genius for war to point out that he adapted rather than originated his tactics. He was the heir not only of French Revolutionary tactics but also of an army of battle-hardened veterans who had won some notable victories over the allies. From the old royal army he inherited the system of dispersion and concentration of divisions and brigades, as developed by Saxe

and Marshal de Broglie. And on the eve of the Revolution, Jean Baptiste de Gribeauval's artillery reforms had reduced the weight and increased the mobility of regimental guns.

Bonaparte was not a great battlefield tactician. He was at his best in that hybrid between tactics and strategy known as "grand tactics"—the assembling of units prior to battle for a last-minute concentration by forced marches on the battlefield itself. No longer could an adversary refuse combat, as in the days of linear tactics. Bonaparte forced such an opponent to fight by sending a column around to threaten his line of communications. When the enemy was brought to bay, Bonaparte could summon his own outlying columns as mobile reserves in less time than could the armies trained for linear tactics.

The preliminary swarms of skirmishers, the cannonading by regimental guns firing grapeshot at close ranges, the battlefield concentration, and the attack by bayonet columns of infantry—these were the four stages of Bonaparte's early victories. Some of them were gained by envelopment, some by penetration, and others by plain frontal assault, according to the dictates of his intuition.

**4. Tactics of the Empire.**—Every conqueror runs the risk of teaching the art of war to his opponents, and Napoleon, as emperor, found his own tactics being used against him with increasing skill. In the Battle of Eylau (1807) 7,000 Russian reinforcements appeared at the critical moment after the delay of the French concentration by a snowstorm. Napoleon barely escaped defeat at an appalling cost in killed and wounded.

Two years later, in the battles of Aspern-Essling and Wagram, the archduke Charles (*q.v.*) and his Austrian army gave Napoleon some anxious moments. France was weary of war and, as the quality of infantry conscripts declined, the emperor placed more reliance on bulk. He used artillery in great masses, and on the field of Wagram he sent an enormous hollow square of 30,000 men to advance on the Austrian centre behind 104 guns. This was the decisive blow, but the victory had been won at a price of 23,000 French killed and wounded.

**5. Wellington's Tactics.**—At a time when other generals were imitating Napoleon's methods, the duke of Wellington defeated French columns with linear tactics and depended on seaborne supplies while outmaneuvering an enemy living on a country eaten bare. He too was an adapter rather than an originator, for the British tactical system was largely the creation of Sir John Moore. In 1803, training troops to meet an expected Napoleonic invasion, he reduced the standard three ranks to the two-rank line of the American Revolution. He applied another American lesson by organizing three regiments of riflemen for his light division, soon to win fame as the most celebrated unit of British battles in Spain.

Moore was killed in his first peninsular operation, but Wellington applied his tactics so successfully as to become one of history's few unbeaten generals. The French, as Europe's masters, felt obliged to attack. Their opponent profited by being able in every major battle to choose his own ground and draw up his "thin red line" behind a low ridge. This gave him the double advantage of protecting his men from ricocheting cannon balls and compelling the French bayonet columns to advance uphill. A screen of skirmishers from the light division was deployed along the forward slope. Since their rifles outranged French muskets, they were able to harass the enemy columns with aimed fire while the British artillery thinned them with shrapnel. The two-rank line gave the redcoats a wider front for musketry, and Wellington met the main French shock with steady platoon volleys. If the enemy wavered, he ordered a British bayonet counterattack.

This was the tactical formula, repeated with few variations, which won victories over Napoleon's marshals for five years in Spain. Wellington proved to be a match for the French in swift concentrations, and on one occasion his light division completed a march of 43 mi. in 22 hours. But it was with infantry firepower that he beat opponents who trusted too much in the bayonet, for Napoleon had refused to adopt the rifle and neglected musketry training in spite of his assertion, "The power of infantry lies in its fire." (See also *PENINSULAR WAR*.)

**6. Half a Century of Transition.**—At Waterloo, Wellington needed only the tactics that had won for him in Spain. But an

era came to an end on that June day in 1815, when infantry, cavalry, and artillery were in close contact and could be controlled by the general as easily as a regiment a century later. All this was changed by the widespread adoption of the percussion cap and long bullet, which multiplied the range as well as accuracy of the rifle and made it a universal military weapon. No longer was it possible to place the guns in front of the infantry, as was done sometimes during the Napoleonic era, with the cavalry close behind. No longer was it possible to mass cannon only 500 yd. from the enemy, as at Borodino, and blast a bloody path to victory. Thus the old battle order, which had changed but little in essentials since the day of Gustavus Adolphus, was relegated to the past. To command an army as Wellington did at Waterloo was out of the question; to render its separate parts cooperative demanded staff work and not merely a powerful voice.

During the half century preceding the American Civil War, inventions came so rapidly that soldiers could not keep pace. The revolver and repeating carbine opened up new vistas for the cavalry and rendered obsolescent the charge of lancers. Rifled and breech-loading fieldpieces worked a revolution in artillery tactics, just as the telegraph, the railroad, and the steamship made it necessary to revise previous ideas of military transport and communication.

Few precedents were available when green armies of citizen-soldiers met in the opening engagements of the American conflict. But if they had more to learn, they had less to forget than the tradition-ridden soldiers of Europe. And before the four-year struggle ended, the Americans had put into effect many of the tactics that would shape the outcome of World War I.

**7. The American Civil War.**—Four million men bore arms in the American conflict. More than 2,000 combats took place, of which 149 were of enough importance to be called battles. Yet these far-flung operations were dominated throughout by the defensive power of the rifle, supported by the axe and the spade.

The railway gun, the land mine, the wire entanglement, the observation balloon, the hand grenade, the field telegraph—these were some of the innovations or revivals of the Civil War. But they were second to the demonstrated ability of the man in the rifle pits to hold his own against three attackers. Since most of the operations occurred in wooded country, soldiers of both sides learned to cut "head logs" with firing slits to give added protection along the parapets of trenches. Generals were taught by experience that marksmen in log-faced earthworks, supported by rifled artillery, could seldom be dislodged except at a ruinous cost in casualties. Lee at Gettysburg and Grant at Cold Harbor—the best tacticians of the war—met with bloody repulses when they underestimated the firepower of opposing riflemen.

On the other hand, paradoxical as it may seem, the defensive power of the entrenched rifleman enabled Lee to launch successful attacks on opponents with a material advantage. Relying on the proved ability of one rifleman to stand off three adversaries, the Confederate general dared repeatedly to divide his army in the face of a more numerous enemy. At Second Bull Run, for instance, Jackson "contained" more than double his own strength in a holding battle until Lee could arrive the next day and deliver the decisive counterstroke. It was Lee's turn at Chancellorsville to fight a defensive battle with half his army while Jackson led the other half around the Union right in a surprise flank attack, thus winning one of history's few authentic victories over two-to-one numerical odds.

European soldiers professed to see in the Civil War only the incoherent clashes of armed mobs, and in 1870 the French and Prussians made it evident that they had learned nothing from the American precepts. They sent cavalry in suicidal charges against infantry armed with breech-loading rifles with an effective range of 1,000 yd.; they took needless losses from rifled artillery as the penalty of close formations; and they persisted in infantry frontal attacks despite the fact that neither side succeeded in taking a single position by such tactics.

## VI. WORLD WAR I

**1. The Battle of the Marne.**—It was the tragedy of World War I that the century of comparative European peace since

Waterloo seemed to have made romanticists out of the professional soldiers who held in their hands the lives of millions of conscripted citizens. Despite the lessons of the American conflict, confirmed by the machine guns of the Russo-Japanese War, France's generals of 1914 had a mystical faith in the *offensive à outrance*—the headlong offensive, compounded of mass, velocity, and morale. They believed that the prewar scale of two machine guns to a battalion was adequate; and as late as 1915 the British commander Sir Douglas Haig asserted that it was "a much overrated weapon" and agreed that the French scale was "more than sufficient." The German generals were more realistic, but they too had complete faith in the offensive and regarded any reference to defensive advantages as bordering on defeatism. Both the French and German tacticians considered a defensive action excusable only when "each man will die in place rather than give ground."

The Germans, who were better prepared at the outset, seemed to be proving their case as they swept through Belgium and northern France. The French soldiers, uniformed in red breeches for the sake of morale, endured frightful losses. And since the German generals held that "the abandonment of close-rank formations is an evil which should be avoided whenever possible," their troops in turn provided the French artillery with lucrative targets.

In the Battle of the Marne the French stopped the invaders by taking advantage of blundering last-minute revisions in the German envelopment plan. Then began the "race to the sea" which was to result in a continuous front of trenches from the Channel to the Alps. The German losses of the first four months were 747,465 killed and wounded; the French had 854,000 casualties during the same period.

**2. Deadlock on the Western Front.**—In the spring of 1915 the entente nations believed that artillery was the key to the deadlock. But even after a prolonged bombardment by 1,140 pieces of heavy artillery, 53 French infantry divisions were able to advance only 3,000 yd. on a 12-mi. front. The enemy simply weathered the storm of steel in deep dugouts until the barrage lifted, then manned the machine guns which cut down attackers plodding across no-man's-land under heavy burdens of equipment.

The Germans risked the censure of neutral nations in an attempt to win a decision with poison gas in the Neuve Chapelle sector. But the Canadians held out until they could be reinforced, and millions of soldiers were soon carrying gas masks as all armies resorted to chemical warfare. Steel helmets also were generally adopted as protection against shell fragments.

The entente nations made a bid for victory in 1915 by launching a land-and-sea assault on the Dardanelles for the purpose of knocking Turkey out of the war and battering down "the unlocked back door" of the Central Powers. A costly failure, after an eight-month campaign, was blamed on the supposed impossibility of conducting a major amphibious operation against modern weapons. Actually, as time was to prove, British and French repulses on the Gallipoli Peninsula resulted from violations of basic tactical principles. (See DARDANELLES CAMPAIGN.)

By 1916 both sides recognized the dependence of ground operations on air warfare (see AIR POWER). The two great campaigns of the year were the German offensive at Verdun and the Franco-British offensive on the Somme. New infantry tactics were introduced by the Germans as specially trained combat groups, armed with flame throwers, advanced after a terrific bombardment. Verdun became known as "the sausage grinder" as the struggle continued for ten months with losses to the French of 442,000 men and to the Germans of 278,000. Although neither side won the battle of attrition, the French heavy artillery and chain of underground forts stopped the enemy. At Verdun, moreover, sweeping changes in tactics were indicated when the French demonstrated that an army could be supplied by motor transport.

The Franco-British offensive on the Somme turned into another heroic slaughter. German defenses in depth, extending as far back as 10 mi., frustrated every attempt at a worthwhile penetration, and "gains" of a few hundred yards were recorded in London headlines. The British made a premature and unsuccessful use of tanks, but lack of planning and preparation actually served to retard the progress of armoured warfare.

**3. The Offensives of 1917.**—The western front was not the only theatre of war, but it was recognized that France would be the area of ultimate decision. Entente generals still trusted in the spring of 1917 that by increasing the density of artillery the infantry could make headway behind a rolling barrage timed to the advance. But even a ratio of a gun to 6 yd. of front was not enough, and the German machine guns continued to reap their deadly harvest.

It had been necessary for a civilian, David Lloyd George, to provide the British Army with a realistic scale of machine guns and trench mortars in spite of the reluctance of Gen. Douglas Haig and Lord Kitchener. Another civilian spoke for the dead of France when Premier Georges Clemenceau remarked that "modern war is too serious a business to entrust to soldiers."

Although Belgian engineers had warned against destroying the drainage system of reclaimed lands, 103,000 tons of shells were fired in the preliminary British bombardments of the third Battle of Ypres, known to the soldiers as Passchendaele. Mustard gas was added to the horrors of the 100-day battle as both armies wallowed in the swamp created by 4,300,000 British shells. Haig's gains were negligible despite 300,000 casualties, and the Germans considered Passchendaele "the supreme martyrdom."

From the entente viewpoint, one of the few consolations of a gloomy year was the British breakthrough at Cambrai on a 6-mi. front with 381 tanks supported by infantry. Attacking by complete surprise, after a last-minute hurricane barrage, the clanking cavalcade ripped through defenses in depth and took 7,500 prisoners and 120 guns at a low cost in casualties. Adequate infantry forces had not been provided by high-level British generals who envisioned a cavalry exploitation, and the territorial gains of Cambrai were lost to a German counterattack. Even so, the operation had demonstrated that armour was the key to a decision on the western front. (See also CAMBRAI, BATTLE OF.)

The Germans had meanwhile developed a key of their own in a new concept of offensive tactics known as "infiltration." It called for the rapid advance of dispersed "storm groups," armed with automatic rifles and light mortars, preceding the main body of infantry. These specialists were to probe for weakness and break through wherever they could find an opening. Their mission was to surprise enemy machine guns and artillery from the flanks and rear while leaving the strong points to be enveloped frontally by following waves of infantry, closely supported by artillery and tactical aircraft. These new tactics of infiltration, carried out by secretly trained troops, promised to create enough demoralization for a penetration as far back as corps command posts and communication centres.

Leaders of both sides realized early in 1918 that it was destined to be the year of decision. All the nations which had participated from the beginning were war-rotten except Great Britain and Germany, and it was a question whether the newly trained U.S. divisions could cross the Atlantic in time to compensate for the defection of Russia, convulsed by revolution.

**4. The Mobile Warfare of 1918.**—Infiltration won the first round. The German spring offensive in Picardy resulted in gains for a few days such as the western front had not known since 1914. Within a week a salient had been extended to a maximum depth of 40 mi. in the British sector by German columns which threatened to drive to the sea. Then, suddenly, the attack ground to a halt and the front was stabilized once more.

This loss of momentum was no coincidence. What had happened was that the Germans had outrun their supplies, for the rail transportation and horse-drawn artillery of 1918 were not adequate to nourish a rapid advance. Gen. Erich Ludendorff made four bids for a decision and each time the early gains merely resulted in creating another salient and two more German flanks.

The last effort, on July 15, 1918, was a complete failure. Attacking on the Champagne front, the Germans were trapped in the French elastic defenses planned by Gen. Philippe Pétain. Here, for the first time in the war, land mines were used on a large scale, and the attackers never reached the main French positions.

The riposte came three days later when Americans and French Moroccans counterattacked on July 18 along the right face of the

salient created by the German drive to the Marne. Complete surprise was achieved by rushing the assault troops up in trucks under cover of darkness. Without any preliminary bombardment, the infantry advanced at dawn with 352 tanks and penetrated so deeply as to threaten the whole salient when other French and American troops attacked the opposite face. Before the Germans could pull out, they left 30,000 prisoners behind and suffered about the same number of killed and wounded.

The precept of motor transport set at Verdun in 1916 bore further fruit as entente generals learned that they could gain surprise unfailingly by these tactics. Dispensing with bombardment and bringing the assault forces up in trucks meant that there would be neither ammunition dumps nor troop concentrations to warn the enemy by means of his aerial observation.

The Amiens salient was next to be reduced as 13 British divisions attacked on Aug. 8 with 450 tanks while armoured cars manned by automatic riflemen spread confusion in German rear areas. On Sept. 2 another British attack struck the enemy in Flanders, and on the 12th an army composed of new American divisions wiped out the Saint-Mihiel (*q.v.*) salient.

The end was in sight during October as the British on the left and French in the centre rained blow after blow, striking by surprise when and where they were least expected. These victories stemmed in large measure from the pressure exerted on the enemy as the American troops on the right slugged their way forward in the 46-day Battle of the Meuse-Argonne against an enemy who was using a fourth of his entire strength on a 20-mi. front in difficult terrain.

## VII. WORLD WAR II

**1. The Post-World War I Reaction.**—During the postwar years the reaction of the former entente nations was in the direction of defensive tactics. The casualties inflicted by the machine gun were remembered when the victories of the tanks were forgotten. This tendency went so far as to resemble in some instances the wishful tactical thinking of 1914 in reverse.

The French, with traumatic memories of two German invasions in half a century, translated their theories of the all-powerful defensive into the concrete and steel of the Maginot line—a bristling belt of underground forts and tank traps extending from the Vosges westward to the Ardennes, where it was believed that the hills and woods would turn back armoured columns. The British, as their modern counterpart of the Great Wall of China, had a defensive military philosophy, the main tenet of which was that postwar improvements in weapons added to the risks and perils awaiting a future aggressor.

The tactical euphoria of the former entente nations was shaken in the 1930s by successful Japanese, Italian, and German aggressions. When the Spanish Civil War served as a rehearsal for Russian as well as German and Italian tactics, it was belatedly realized that improvements in weapons favoured the offensive to such an extent as to endanger laggards in preparations. Tanks were many times as fast and powerful as those of 1918; motorized artillery, on rubber tires, showed an enormous gain in mobility over horse-drawn, iron-wheeled vehicles; and motor trucks poured from the assembly lines by the thousands to solve the transport and supply problems of a new lightning warfare.

**2. Early German Victories.**—Any doubts as to the effectiveness of German preparations were dispelled during the first two years of World War II as Hitler's armoured columns swept on to victory after victory. The Maginot line was outflanked by German tanks which broke through in the Ardennes and drove from the Meuse to the Channel in a week, cutting off 335,000 men of the British expeditionary force and attached French units. It seemed an authentic miracle when these beleaguered troops were evacuated by sea from Dunkerque (Dunkirk), leaving their heavy arms behind, as the German columns raced on to the occupation of Paris.

From the late summer of 1939 to the autumn of 1941 the Germans never met with a serious reverse in land warfare. Their triumphs were gained with such swiftness, such precision, and economy of means that the blitzkrieg, or lightning war, was popu-

larly accepted as a brilliant new tactical system. Actually it was the legitimate offspring of the infiltration tactics of 1918 mated with the tank tactics. There was nothing new that could not be explained by the gains of two decades in the offensive powers of such weapons as the tank (*q.v.*), motorized artillery, and tactical aircraft. With a few exceptions such as antiaircraft guns, defensive weapons had lagged in the armament race while armour and artillery were leaping ahead from the 3 mph of 1918 to the 30 mph of 1938.

The French Army of 1940 was essentially a World War I instrument, patched here and there with tactical changes, just as the Maginot line was in effect a modernized western front. Despite warnings that the enemy might strike through the gap in the Ardennes between the French and Belgian fortified lines, the French in the Sedan area were unprepared for German "tactics of the space and gap." Only three penetrations on a 12-mi. front, each no wider than 2,000 yd., were enough as the starting point of a major breakthrough. Like a flood enlarging holes in a dam, tanks and combat groups in armoured cars poured into the gaps, depending on surprise and speed as well as Stuka dive bombers for flank protection. Their direction of attack was lateral as well as forward, the object being to widen the gaps for following German forces. Within four hours the invaders were overrunning command posts and communications centres in French rear areas too demoralized for effective resistance. The Maginot line had simply been bypassed and left behind by the torrent of armoured invasion which inundated northern France in a week.

Predictions that Hitler would meet his downfall in Russia were not upheld by military results of the first few months. The Russian Army, like the prehistoric mastodon, seemed doomed to extinction by its very bulk as German armoured envelopments swallowed up prisoners by the division and corps. Political factors influenced tactics when Hitler's doctrines of racial superiority led to cruelties which drove Russian peasants into guerrilla warfare. Effective resistance of this sort, combined with Soviet scorched earth tactics and a seemingly endless reserve of man power, enabled the Soviet Army to survive until the German transport bogged down in autumnal mud.

Even so, the tactics of Hitler's armies had been so successful during the first two years that a serious defect might easily have been overlooked. That was the apparent lack of preparation for amphibious tactics in a global war. Although the British Isles were desperately short of arms after the Dunkirk evacuation, the Germans had neither the training nor the equipment to land troops across a few miles of water. In Crete they proved their mastery of airborne attack techniques, but a clumsy attempt at an amphibious combat landing ended in disaster.

**3. The War in the Pacific.**—After the United States and Japan entered the lists as enemies, the war in the Pacific necessarily consisted in large part of amphibious operations. And despite the tradition that the English-speaking peoples are never prepared for war, events showed that the U.S. forces had developed an effective system of amphibious combat tactics. Three continents were opened up to invasion by this system, which won a score of major victories without suffering a single major defeat. In the 1920s the "Orange" plans, adopted by the United States for offensive operations in the event of war with Japan, called for attacks on that nation's shield of fortified islands in the Pacific. By a directive (1927) of the joint board of the U.S. Army and Navy, the Marine Corps was given the mission of preparing for the conduct of landing operations.

There were few 20th-century precedents, though the Gallipoli failure of 1915 supplied plenty of object lessons. Weapons and techniques had to be improvised where none had existed before. Strange landing craft and amphibian vehicles evolved as inventors were encouraged to submit designs. Large-scale simulated assault landings were made annually in fleet exercises of the 1930s held at Caribbean and Pacific bases. New bases were established, new amphibious units formed, and new types of ammunition developed. As a result, the United States possessed on the eve of World War II what Maj. Gen. J. F. C. Fuller has described in his history of that conflict as "in all probability . . . the most far-

reaching tactical innovation of the war." (J. F. C. Fuller, *The Second World War*, p. 207, Eyre & Spottiswoode, London, 1948.)

**4. U.S. Amphibious Victories.**—Within a year the outer barrier of Japan's island defenses was breached by U.S. ship-to-shore assaults. Months of detailed planning and rehearsal preceded each operation. Supply ships were "combat-loaded" so that tanks, trucks, artillery, fuel, rations, and water would be made available to the landing force in the order needed. Intricate firing plans were drawn up for artillery and rocket bombardments to scorch the target area while armoured landing craft took the assault troops to the beaches under cover of air strikes. The transition from one element to another was the critical moment. Maneuver was seldom possible during the controlled chaos of the landings and repulse meant a disaster which could hardly be retrieved. Once the beachhead was won, special units unloaded cargo ships, established supply dumps, and regulated traffic while the assault troops drove inland with the support of tanks and artillery as soon as they could be landed.

U.S. ship-to-shore assaults were conducted by troops using Navy and Marine techniques. The Army trained special units for shore-to-shore assaults, utilizing the same landing craft. New Guinea was thriftily reduced by these troops in coastal landings which bypassed strong Japanese garrisons and left them behind to "wither on the vine."

The amphibious offensive had become by 1943 the most decisive tactical system of World War II, not only in the Pacific theatre but also in North Africa and Europe. Neither the Japanese nor the Germans ever found the clue to a successful defense. Landings in Morocco, Algeria, Sicily, and Italy were followed by the climactic operation of June 6, 1944, when 4,100 ships put ashore five divisions complete with tanks and artillery on the beaches of Normandy. Nine days later in the Pacific an equally successful amphibious combat landing on Saipan brought American bombing planes within striking distance of Tokyo and led up to the assaults on Iwo Jima and Okinawa which made Japanese defeat inevitable.

**5. Wide Variety of World War II Tactics.**—So varied were the geographical and climatic conditions that it is difficult to generalize about the tactics of a war in which a score of major campaigns were being waged simultaneously in different parts of the world.

Tank battles on the plains of Russia began with tremendous artillery "preparations" and ended with armoured envelopments in which as many as 20 divisions were surrounded. In such instances the beleaguered forces were sometimes able to form a "hedgehog" or circular formation, and fight their way out of the encirclement with the aid of airborne supplies. In the long run it was a grinding war of attrition in which the Russians gained the upper hand largely as the result of arms and equipment delivered by Britain and the United States in spite of heavy losses suffered by sea convoys.

Armoured columns in the desert warfare of North Africa achieved a mobility which makes their operations instructive to the student of tank tactics. But Gen. Erwin Rommel's defeat was foreordained by the inability of the Germans to mount an amphibious assault on Malta. The campaign in the desert was actually a battle of supply, and while the British held Malta they could provide air escorts for convoys of cargo ships in the Mediterranean.

On all fronts, special units equipped for special tasks were employed to an extent never known before. Infantry was the arm of decision in most operations, but it became standard practice to organize task forces ranging in size from platoons to divisions, reinforced by tanks, artillery, rocket launchers, or such other support weapons as might be indicated for the specific mission.

So potent were the missile weapons of World War II that survival for the individual soldier depended on cover and concealment. Small infantry units took on increasing importance as experience taught that latitude of decision must be left to troops in direct contact with the enemy, since victory often depended on the initiative and intelligence displayed by platoon commanders.

Some of the infantry combat teams became standardized. The British commando units, made up of soldiers, sailors, and marines organized on a permanent basis, conducted raids throughout the

war. In Burma the British developed special penetration groups of infantry to operate behind the enemy's lines, attacking headquarters and supply dumps while being supplied by air.

All armies made an unceasing effort to gain a decision by the introduction of new weapons and tactics. But the German V-1 jet-propelled bomb came too late to change the outcome, as did the more formidable V-2 rocket after the Allies had broken through in Normandy and swept across France to the German frontier. (See **ROCKETS AND GUIDED MISSILES.**)

On the Allied side, the 2.36-in. rocket launcher and the 57-mm. and 75-mm. recoilless rifles provided the infantry with weapons which were tank-killers under favourable circumstances. The VT (variable time) artillery fuze enabled a shell to be exploded automatically in electronic reaction to waves reflected from the target itself. These tactical innovations seemed trivial, however, after the atomic bomb was dropped on Hiroshima on Aug. 6, 1945. (See further **ATOMIC ENERGY: Bomb Explosions.**)

Thus, at the conclusion of World War II the participants were confronted by the fact that "the bomb" might render obsolescent all the tactics of victory. Even the discovery of gunpowder does not represent a comparable turning point in tactical history, for the first handguns were not as deadly as the crossbow. Nor did gunpowder have a rapid evolution, considering that the TNT of the 20th century was only about twice as powerful as the explosives of the Middle Ages. Yet the world of 1945 had to adjust itself overnight to the necessity of revising all military standards of the past. See further **ARMY; ARTILLERY; INFANTRY.**

## VIII. NUCLEAR AGE

**1. War in Korea.**—It is one of history's ironies that the first war of the strident new nuclear age should have been waged with tactics reminiscent of the western front in 1917. Combat in Korea (1950-53) consisted for the most part of infantry fights with small arms on the platoon and company levels. (See **KOREAN WAR.**)

Called a "police action" at first, the intervention of 1950 proved during its first year to be the fourth most costly military effort of U.S. history. After a preliminary period of mobility, the United Nations and Chinese Communist forces faced each other in lines of trenches and defenses in depth extending across the peninsula. Neither side attempted to hold its front in force. Bunkers and outposts on the main line of resistance sheltered combat groups whose duty it was to maintain contact with the enemy and warn of a large-scale attack. Patrols ranging in size from an infantry squad to a platoon crept through no-man's-land in the darkness as both sides found the ambush an effective tactic.

The Korean War showed that even in the nuclear age an Asian peasant army using semiguerrilla tactics can be formidable in mountain terrain suited to its operations. (See **MOUNTAIN WARFARE.**) Atomic weapons would not have been effective in such a war, and the Korean experience made it appear unlikely that sound infantry tactics would soon become outdated.

**Tactical Innovations.**—The two great tactical innovations of the war were the combat helicopter and the revival of infantry body armour. Rotary wing aircraft had been developed too late for an extensive test in World War II, but in Korea the helicopter proved its value immediately in tactical as well as logistical respects. A U.S. brigade commander found it possible with the use of rotary-wing transportation to maintain combat control over units 25 mi. apart. When a U.S. squadron of transport helicopters reached the front, it was demonstrated that a battalion of infantry could be lifted in a few hours to the main line of resistance in mountainous country where an all-day march would have been necessary. On an occasion when an infantry company was surrounded, six helicopters flew in ten tons of ammunition and evacuated casualties, thus enabling the encircled troops to fight their way out of the trap.

The revival of body armour, after a lapse of several centuries, was made possible by 20th-century plastics. Nylon pads and thin slabs of Fiberglas were combined in a sleeveless vest weighing about eight and a half pounds and allowing freedom of movement. The armour was capable of stopping .45-calibre automatic pistol bullets, submachine gun slugs, and most shell, mortar, or grenade

fragments of a velocity less than 1,100 ft. per sec.

All U.S. combat troops in Korea were equipped with the garment before the war ended. On the basis of U.S. Army and Marine Corps surveys, it was established that body armour prevented from 60% to 70% of chest and abdominal wounds while reducing the severity of 25% to 30% of the wounds resulting from penetrations. Aside from humanitarian aspects, this meant that a large proportion of the enemy's most effective antipersonnel weapons were rendered useless. The tactical value of body armour was increased by its contribution to morale. Troops on the defensive had their foxholes and trenches, but the vest-protected men advanced in the open during an attack, when protection was most needed. The result, according to U.S. infantry officers in Korea, was a marked increase in combative spirit.

**2. Tactics After Korea.**—At the end of the Korean War, the military problems of the nuclear age were no nearer to solution because of lessons taught by that war. There was some reassurance, however, in the fact that neither side in an ideological conflict had even threatened to use atomic weapons, though it was known that the Soviet Union as well as the United States had conducted successful atomic tests. As further evidence that warring nations could practise restraint, it might have been cited that poison gas, one of the most deadly weapons of World War I, was not used in the next two wars, though all armies were in possession of far more destructive gases than those of 1918. Nor was any attempt made to gain a military advantage by the possibilities for wiping out entire populations offered by germ warfare.

During the first decade of the nuclear age, the U.S. tests conducted at Bikini Atoll in the Pacific and Yucca Flats in Nevada encouraged soldiers to believe that tactics might be adjusted to the new weapon by means of troop dispersion on a scale never envisioned before. Then came the announcement of the hydrogen bomb in the 1950s and predictions that thermonuclear weapons with fantastic destructive power as high as 45 megatons (45,000,000 tons of TNT) were being developed. (In 1961 the U.S.S.R. detonated a device of even higher yield.) Contemplating such a prospect military men could only admit that they knew of no tactical antidote to a force capable of wiping out a province or a metropolitan city with a single explosion. It was no longer war when such weapons were used; it was sheer insane destruction. And there was not much consolation in the thought that an enemy could be paid back in kind.

A result of these trends was the pentomic infantry division announced by the U.S. Army in 1957. Firepower, mobility, and dispersion suited to the nuclear age were the goals sought in the most sweeping changes made by any army up to that time. The three infantry regiments of the triangular division, with their nine battalions, were replaced by five battle groups, each comprising approximately 1,400 officers and men.

**3. Later Tactical Organization; Vietnam.**—In 1961 the pentomic division, designed for employment in nuclear warfare, was abandoned because it proved too cumbersome and inflexible for use in "brushfire" wars involving limited forces and conventional weapons. Its place was taken by a new divisional structure consisting of an "all-purpose" divisional base with three brigade headquarters to which could be attached varying numbers and types of combat maneuver battalions (see **DIVISION, MILITARY**). This reorganization provided a division whose size (10,500 to 19,950 men) and equipment could be tailored to each specific mission and to the type of terrain encountered in its accomplishment. Other results of the change were improved balance between nuclear and nonnuclear firepower, greater internal flexibility, and an improved command and control structure.

At about the same time a unified command was established to include the Strategic Army Corps (STRAC), designed for fast deployment by air, and the Tactical Air Command (TAC) of the U.S. Air Force. Thus was created a mobile striking force of ground troops adequately supported by aviation units. This new command helped alleviate an Army complaint that ground forces were without adequate tactical air support since the diversification of command caused by the separation of the Army and Air Force in 1947.

Still another change in tactical thinking occurred during the war in Vietnam in the 1960s with the establishment of special forces for carrying on small-unit guerrilla warfare behind enemy lines or cooperating with indigenous populations in antiguerrilla operations. The helicopter again proved its value in the 1960s in Vietnam where troops and supplies, including heavy equipment such as bulldozers, could be speedily transported over impassable jungle areas. A significant new development was the introduction of armed helicopters that played an active role in attacking the enemy. Helicopter flight crews wore a lightweight, flexible "flak jacket" that covered the upper torso. Marine Corps ground troops were not required to wear such protective body armour, because of the heat and humidity, but it was available for those who chose to wear it. (LN. Ms.; X.)

### IX. NAVAL TACTICS

Naval tactics may be said to begin when the opposing forces first "sight" each other visually or by means of radar. Tactical maneuvers are then instituted with the object of employing weapons to the greatest possible advantage, usually by concentrating overwhelming strength on one portion of the enemy fleet, and of preventing the effective employment of the enemy's weapons. Though victory won at sea has generally been the consequence of successful strategic dispositions, tactics have always set the final seal to that victory by sinking, capturing, or putting out of action a substantial proportion of the enemy fleet.

Naval tactics have been determined chiefly by the weapons mounted in fighting ships. Thus the principal weapon of the oar-propelled galley was the ram, and throughout its long period of dominance (chiefly in the Mediterranean) fleets endeavoured to disable enemy ships by ramming, and then to capture them by boarding. The arrival of the cannon in the 14th century, and still more the mounting of heavy guns on the broadside of fighting ships in the mid-16th century, rendered the galley obsolescent. The purpose of fleet commanders now became to maneuver under sail so as to bring their full broadsides to bear on the enemy in the most effective manner. Because a sailing ship's hull was least well protected at the bow and stern (especially the stern), and shot fired into her from right ahead or right astern could travel most of the length of the ship and so wreak great havoc, a much-favoured tactical purpose was to achieve a position from which the enemy could be "raked" in that manner. The easiest way of accomplishing this was by "breaking the enemy line." Hence arose the importance attached throughout the era of sail to gaining the windward position or "weather gauge." Though the enemy line could also be broken from the leeward position, as George Monck did in the Four Days' Battle (1666) and George Rodney in the Battle of the Saints (1782), it was far easier for the holder of the weather gauge to accomplish such a maneuver. Breaking the line also destroyed the enemy fleet's tactical cohesion, so making it possible to overwhelm individual ships by bringing greatly superior strength to bear on each of them in turn.

The regularization of tactical maneuvers under sail can confidently be ascribed to the issue of the first English *Fighting Instructions* in 1653, which made the line-ahead formation obligatory in battle. In the Anglo-Dutch wars of the 17th century both sides normally engaged in the line-ahead formation, which led to a large number of stubbornly fought battles from which sometimes one and sometimes the other side emerged victorious. With the decline of the United Provinces and the emergence of France as a naval power toward the end of the 17th century the French school of naval tactics became influential. The principles formulated by Paul Hoste, Sébastien Bigot de Morogues, and others were in general more elastic than the English *Fighting Instructions*, which continued to exert a cramping and restrictive influence, leading to many unsatisfactory actions in the Anglo-French wars of the early 18th century.

Tactical success depends largely on the possession of an efficient system of communication between the admiral and his fleet, and the limitations of the early signal books often produced serious misunderstandings. It was a British admiral, Richard Kempenfelt (1718-82), who initiated a revolution in signaling, and so in the

ease and confidence with which tactical maneuvers could be carried out. This, allied to the genius of Nelson, which refused to be shackled by *Fighting Instructions*, brought the British Navy to its peak of tactical success in the Napoleonic Wars.

The smoothbore gun mounted in wooden sailing ships remained the dominant weapon at sea until the Crimean War (1854-56), showed that the explosive shell had made wooden ships totally obsolete. When steam propulsion began to release warships from their long dependence on the wind, and improvements in gun design made action at much longer ranges possible, a new era of naval tactics opened. The first action between ironclads took place (March 9, 1862) during the American Civil War, which also saw the first use of mines and torpedoes. In the Austro-Italian War there took place the first engagement between squadrons partly composed of ironclads off Vis (Lissa) (July 20, 1866), and the success of the Austrian admiral Wilhelm von Tegetthoff in ramming and sinking his adversary's flagship caused a wave of enthusiasm for such tactics. In spite of the fact that the range at which actions could be fought was increasing all the time some battleships continued to be fitted with rams until well into the 20th century. The first occasion on which the tactics of the era of steam propulsion and the long-range gun were tested on a large scale was in the Battle of Tsushima (May 27-28, 1905), when the Japanese admiral Heihachiro Togo, by skilful and resolute handling of his fleet, almost annihilated his Russian adversaries.

In 1906 the launching by the British of the all-big-gun battleship "Dreadnought" ushered in the brief final period of the tactical dominance of the long-range gun. Of the actions fought during World War I the Battle of Jutland (*q.v.*) is by far the most interesting tactically. The British commander in chief, Adm. Sir John Jellicoe, gained a position of tactical advantage after he had deployed from his cruising disposition into line of battle; but his centralized and rigid system of tactical control resulted in the sacrifice of that advantage, and the greater part of the German High Seas Fleet, though markedly inferior in strength, escaped in safety to its bases during the night. The battle revealed serious defects in the British armour-piercing shell and in the magazine protection of their capital ships, which resulted in their suffering much the heavier losses.

Almost from the beginning of World War I the submarine exerted a profound influence on naval tactics as well as strategy. Together with the mine, submarines made close blockade of enemy bases impossible; they produced the need to screen the heavy ships of the fleet with antisubmarine vessels; and they forced the combatants to expend a very large effort on defending their principal ports and bases against penetration by submarines. In the North Sea the Germans frequently tried to catch the British heavy ships as they were entering or leaving their bases, and to draw them over a submarine trap while at sea: but these tactics rarely produced much result—because of the slow speed and limited vision of the submerged submarine. By far the greatest influence of the submarine lay in the field of the *guerre de course* or attack on trade. Almost from the beginning the Germans used submarines against merchant ships, but it was not until February 1917 that they adopted "unrestricted submarine warfare"—torpedoing any merchant ship in the "war zone" around the British Isles on sight. During the "restricted" phase German submarines made an effort to comply with international law, warning merchant ships and using guns to sink them after they had been abandoned. This led to the arming of Allied merchant ships. In the unrestricted phase the submarines almost invariably used torpedoes and often fired while the submarine was on the surface at night, a procedure that amounted to using the submarine as a torpedo boat. In World War II the Germans carried the tactics employed in World War I a stage further by the introduction of group attacks by 20 or even more submarines operating under the direction of the shore headquarters and in loose tactical coordination with each other. The British Navy, especially in the Mediterranean and the U.S. Navy in its operations against Japanese merchant shipping ultimately adopted similar tactics. (See further SUBMARINE: *Submarine Warfare*.)

The most important naval question left unanswered by the

events of World War I was the influence of aircraft on naval strategy and tactics. The conventional view that aircraft were still no more than a valuable auxiliary to the heavy gun prevailed, and all the naval powers continued to build battleships in the period 1918–39. Britain, the United States, and Japan did, however, devote considerable attention to the development of carrier-borne aircraft, and very soon after the outbreak of war in 1939 it became clear that these had indeed replaced the big gun as the dominant weapon. The British carrier air attack on the Italian fleet in Taranto (Nov. 11, 1940), the Japanese attack on Pearl Harbor (Dec. 7, 1941) and their destruction of the British battleship "Prince of Wales" and battle cruiser "Repulse" off Malaya (Dec. 10, 1941), and many other actions all pointed in the same direction. The development of effective carrier air tactics now became the predominant requirement. The purpose was to gain the first sighting of the enemy, and then to launch the air striking forces against the enemy carriers so as to arrive at the most advantageous moment, while fighter aircraft protected their own carriers against the expected counterblow. It was the U.S. Navy that led the field in the development and application of such tactics, and in a whole series of carrier air battles starting with Coral Sea (*q.v.*) and culminating in the battle of Leyte Gulf (October 1944) a decisive superiority was established. The Japanese adopted "suicide" air attacks in reply, but this proved quite inadequate to stem the victorious progress of the U.S. carrier task forces. With the post-war development of the nuclear submarine it seemed possible that the period of the tactical dominance of the carrier aircraft would prove even shorter than that of the battleship. (S. W. Ro.)

**TADZHIK** (Tajik), the original Iranian population of Afghanistan and Turkistan. Tadzhik constitute a majority of the population of Soviet Tajikistan (see TADZHIK SOVIET SOCIALIST REPUBLIC); in the 1960s they numbered about 1,400,000 in the U.S.S.R., with more than 300,000 in Uzbekistan. They com-

prised about one-third of the population of Afghanistan, where their communities have been reported near Kabul in the Herat region, and in a number of localities north of the Hindu Kush.

Tadzhik were the heirs and transmitters of the central Asian sedentary culture that diffused in prehistoric times from the Iranian plateau into an area extending roughly from the Caspian Sea to the borders of China. Here were built villages of flat-roofed mud or stone houses along streams and rivers that irrigated fields of wheat, barley, and millet, and gardens famous for melons and a variety of fruits. Crafts were highly developed, and towns along the caravan routes linking Persia, China, and India were centres of trade networks in the area.

Turks, and later Mongols, flowed westward into the area, and Pushtu speakers (Afghans) gradually pushed northward. As these nomadic peoples settled, they adopted Iranian culture, but in Turkistan many of the Iranians adopted Turkic speech.

The name Tadzhik refers to the traditionally settled Caucasoid people who have retained Iranian speech. Most speak dialects of Persian, but the Mountain Tadzhik or Galcha in the Pamir Mountains speak dialects of two eastern Iranian languages, Pamir and Yagnobi.

**TADZHIK SOVIET SOCIALIST REPUBLIC** (TADZHIKSKAYA SOVETSKAYA SOTSIALISTICHESKAYA RESPUBLIKA; TADZHIKISTAN, or TAJIKISTAN), a republic of the U.S.S.R. which achieved the status of a federal union republic on Dec. 5, 1929. Situated in the southeast of Soviet central Asia, the republic is bordered on the south by Afghanistan and on the east by the People's Republic of China. Area 55,251 sq.mi. (143,100 sq.km.). The capital is Dushanbe, which, from Dec. 1, 1929, to Nov. 11, 1961, was called Stalinabad.

**Physical Geography.**—In general the Tadzhik S.S.R. is high mountain terrain. Its whole eastern part covers the high-level valleys or *pamirs*. The country is traversed by many mountain ranges generally extending east-west, and including the Zeravshan-ski and Gissarski ranges in the west, and the Peter I (Petra Perovogo), Trans-Alai (Zaalaitski) and North and South Alichurski ranges in the Pamirs (*q.v.*). The north-south Sarykolski range forms the eastern frontier of the republic. Communism peak (formerly Pik Stalina; 24,590 ft. [7,495 m.]) and Lenin peak (Pik Lenina; 23,405 ft.) in the north of the Pamirs, and Karl Marx peak (22,067 ft.) in the south are the highest mountains in the Soviet Union.

South of Mt. Communism lies the 50-mi. Lednik Fedchenko, the longest continental ice stream in the world. With the exception of the Tadzhik section of the Syr-Darya (Jaxartes) in the Fergana valley; of the Zeravshan river, which loses itself in the Uzbek desert near Bukhara; and of the Markansu river, which flows into Sinkiang, all the glacier-fed streams are right-bank tributaries of the Amu-Darya (Amu-Dar'ya [*q.v.*]; or Oxus). The Amu-Darya rises in the Afghan Hindu Kush as the Vakhn-Darya and, as the Pyandzh (from Persian *panj*, meaning five; *i.e.*, the five streams which it collects on its way), it forms most of the frontier between Afghanistan and the Tadzhik S.S.R. It then receives the Vakhsh river, which rises in the Kirgiz S.S.R. and is called first Kyzyl-Su ("red water" in Uzbek), and lower down Surkh Ab ("red water" in Persian).

There are many lakes in the Pamirs formed either by glaciers or as a result of avalanches (produced by earthquakes) which dammed existing streams. The largest glacier-formed lake is Kara-Kul, 141 sq.mi. (364 sq.km.) and 780 ft. (238 m.) deep. Among lakes of such tectonic origin the largest and most recent is Sarezkoje Ozero, 38 mi. (61 km.) long and 1,657 ft. deep, formed in 1911.

The country has three types of climate. In the lowlands it is hot and dry, with a yearly rainfall averaging 10 in. and temperatures varying between 31° C. (88° F.) in July and 3° C. (38° F.) in January. In the foothills there is more rainfall and it is cooler.

In the high mountains above 10,000 ft. there is only 3 in. of yearly precipitation and the yearly average temperature is below freezing point.

The northwestern lower slopes are well covered with forest. Many varieties of vegetation are represented, from saxaul scrub and jungle grass, through deciduous and coniferous forest to alpine pasture. Animal life is also varied. In the southern lowlands tigers, deer and many kinds of water birds are found. In the higher plateaus there are antelopes and huge lizards up to 4½ ft. long, and in the Pamirs there are bears and mouflons.

**History.**—The Tadjik (*q.v.*) peoples are of Persian-speaking Iranian stock. They were included in the empires of Persia and of Alexander the Great of Macedonia. In the 8th century the Arabs crossed the Amu-Darya, conquered Sogdiana (*q.v.*; Transoxiana) which was inhabited by Tadjiks, and called it *Mavera un nahr* ("land beyond the river"). Two centuries later the first Turkic invaders (from the northeast) seized *Mavera un nahr*, and in time, as both conquered and conquerors were Muslim, many Tadjiks, especially those in the valleys of Syr-Darya and Amu-Darya, became Turkicized.

Until mid-18th century the Tadjiks were part of the amirate of Bukhara (*q.v.*), but then the Afghans conquered lands south and southwest of the Amu-Darya with their Tadjik population, including the city of Balkh (*q.v.*), an ancient cultural Tadjik centre. Another partition of the Tadjik territory took place in 1895 when an Anglo-Russian commission fixed the northern frontier of Afghanistan on the Pyandzh river and separated the Russian and Indian empires by an Afghan corridor on the Vakhsh-Darya extending to the Chinese frontier.

After the Russian Revolution of 1917 a considerable part of the Tadjik people was included in the Turkistan Autonomous Soviet Socialist Republic established in April 1918. On Aug. 23, 1920, the revolution was extended to the khanate of Bukhara, which embraced most of the territory occupied by the modern Tadjik S.S.R. In Oct. 1920 the Bukharan People's Soviet Republic was declared in being, and early in 1921 the Soviet army captured Dushanbe and Kulyab. From 1922 to the summer of 1923 Tadjikistan was the scene of the Basmachi revolt, and rebel bands under Ibrahim Bek operated in Eastern Bukhara until 1926. In 1924 the Tadjik A.S.S.R. was created as part of the Uzbek S.S.R.; in Jan. 1925 a Special Pamirs *oblast* was created out of the Kara-Kirgiz and Tadjik parts of the Pamirs; and in Dec. 1925 this *oblast* was renamed the Gorno-Badakhshan Autonomous *oblast*. Tadjikistan was thus composed of the following former administrative units: Eastern Bukhara, 7 volosts (rural districts) of the Samarkand *uyezd* (county), the 5 southern volosts of the Khodzhen (later Leninabad) *uyezd*, and 6 volosts of the Pamirs region. On Dec. 5, 1929, the status of the republic was raised to that of Soviet Socialist Republic.

Collectivization of agriculture was carried out in 1928 and 1929 in the face of considerable opposition. There were later periodical purges of the council of ministers and the party apparatus, including one in 1961.

**Population and Administration.**—According to the 1959 census the population was 1,979,897, including 1,051,164 Tadjiks (53.1%), 454,433 Uzbeks (23%), 262,610 Russians (13.3%), 56,893 Tatars (2.9%), 26,921 Ukrainians (1.4%), 25,635 Kirgiz (1.3%), and 12,551 Kazakhs (0.6%). The density of population was 13.8 per sq.km. (about 36 per sq.mi.). The most thickly populated areas are the Leninabad district in the north of the republic and the Gissar and Vakhsh valleys. One-third of the population are town dwellers living in 14 towns and 31 "settlements of town type." The main towns are Dushanbe, Leninabad (*qq.v.*), Ura-Tyube, Kulyab and Kurgan-Tyube.

In the absence of any official statistics it can be assumed that all the inhabitants of the republic other than Russians and Ukrainians are actual or nominal adherents to the Muslim religion.

The government of the Tadjik S.S.R. is the standard one for union republics. Control over every form of government, economic, social and cultural activity is exercised by the communist party. After the administrative reorganization carried out in 1962 the republic consisted of the Gorno-Badakhshan Autonomous

*oblast* (*q.v.*) and a number of *raions* under direct republican administration. Leninabad *oblast* was abolished.

**Education and Culture.**—The culture of the Tadjiks, who constitute a little over half of the population, is Iranian, their language closely resembling the Persian spoken in Iran and Afghanistan, although it has been written exclusively in Cyrillic (Russian) characters since 1940. About 27% of the population is made up of various Turkic elements, mainly Uzbek, and these, with the exception of a few small tribes in the south, stubbornly resist Iranization.

Several newspapers are published in the Uzbek language which is taught to Uzbeks attending school. During the Soviet period the Tadjiks have laid claim to some of the principal Persian poets such as Rudaki and Omar Khayyam. Sa'di, Hafiz and Jami are described as "organically entering" the history of Tadjik literature.

In the 1960s nearly 350,000 pupils were in school and 16,000 in kindergarten. Schools for young industrial and agricultural workers and "middle" special training establishments enrolled about 16,000 students, and more than 18,000 were in the seven higher educational establishments (including the Tadjik State university, established 1948). A branch of the U.S.S.R. Academy of Sciences established in Dushanbe in 1941 became an independent academy in 1951. In Dushanbe there are radio and television transmitters broadcasting in Tadjik, Russian and Uzbek languages.

**The Economy.**—The Economy of Tadjikistan is mainly concerned with the growing and processing of cotton. Industry is principally light and apart from cotton ginning and textile weaving it is connected chiefly with food processing. In agriculture the main crop is cotton, but fruit is grown extensively as well as food grains and technical crops. There is a considerable cattle-breeding industry.

Tadjikistan has about 350 kolkhozes (collective farms) and 40 sovkhozes (state farms). About half of the total sown area is under irrigation. The main canals are the Vakhsh, the Great Gissar, the Great Fergana, and the Northern Fergana. A large area is under cotton, and the yields per acre are among the world's highest.

On the unirrigated lands, principally on the northern slopes of the Turkistan range and in the southeast of the republic, food grains (wheat, barley and millet) are grown and oil grains (mainly flax) are cultivated in the southeast. Stock breeding includes sheep, horned cattle, pigs, karakul sheep, angora goats, Lokai horses and yaks (in the eastern Pamir).

There are cotton-ginning factories in all the cotton-producing valleys, the principal ones being in Dushanbe, Regar and Kurgan-Tyube. Most of the textile weaving is carried on in the Dushanbe cotton *kombinat* (combine). Leninabad is an important centre of the silk-weaving industry. Large factories for the manufacture of carpets and woollen goods are at Ura-Tyube. Cotton-seed oil processing is allied to cotton ginning, the principal centres being Kanibadam, Leninabad, Kurgan-Tyube and Shaartuz.

There are fruit canneries at Kanibadam, Leninabad, Chkalovski and Regar and wineries at Dushanbe, Leninabad and Ura-Tyube. Minerals that are being exploited include lead and zinc (Kansai), fluorspar (Takob) and brown coal (Shurab); oil is produced at Kim and Nefteabad. In its hydroelectrical resources the Tadjik S.S.R. occupies the second place in the U.S.S.R. (after the Russian S.F.S.R.), the main power stations being at Kairak-Kum on the Syr-Darya and at Perepadnaya on the Vakhsh canal. During the 1959-65 seven-year plan a gas pipeline from the Uzbek S.S.R. was planned and under construction.

**Communications.**—There are 160 mi. (258 km.) of standard-gauge and 186 mi. (300 km.) of narrow-gauge railway lines. The main line, connecting the national network, is from Termez to Ordzhonikidzeabad. From Dushanbe to the Vakhsh valley and thence to Kulyab there is a narrow-gauge line. There are main highways between Dushanbe and Khorog, Khorog and Osh, Dushanbe and Ura-Tyube; Kurgan-Tyube and Kulyab also have road links with Dushanbe.

The Amu-Darya is navigable below Faizabadkala. Air transport

is important and airlines join Dushanbe with Moscow, Tashkent, Baku and other towns. (G. E. WR.; K. SM.)

**TAFFETA** is a perfectly flat fabric in which the warp and weft threads are evenly interlaced so that equal numbers appear on the surface. There are two distinct types of silk taffeta, yarn-dyed and piece-dyed. Yarn-dyed taffeta has a stiff handle and a rustle known as "scoop" or "froufrou." It is used for evening dresses and for underskirts for couture dresses in chiffon or georgette. This type of taffeta is also used for academic hood linings. Piece-dyed taffeta, which is soft and washable, is a favourite fabric for linings. It is also used for electrical insulation and in a particularly strong form was much used for parachutes in World War II.

There are a large number of fancy taffetas, the best known being shot taffeta and taffeta chiné or warp-printed taffeta. Taffeta is also produced in yarns of wool, cotton, and man-made fibres. (D. M. LE.)

**TAFF VALE CASE**, a legal action begun in 1900 by the Taff Vale Railway Company in South Wales against the Amalgamated Society of Railway Servants (ASRS), in which judgment was given that a trade union could be sued for damages caused by the actions of its officials in industrial disputes. A number of employees of the company went on strike in August 1900 hoping to raise their wages and to secure company recognition of their union. The company imported nonunion workers in an effort to break the strike and there was much bitterness. Richard Bell, the general secretary of the ASRS, had no confidence in the outcome of the strike, however, and a settlement was reached within a fortnight. The strikers gained virtually nothing, but were protected from the consequences of defeat by the company's promise to take them back to work.

During the strike the company began a legal action in the Court of Chancery against the union, claiming that its picketing went further than the limits laid down in the Conspiracy and Protection of Property Act of 1875. The union held it was not liable for damages caused during the strike, since it was neither a corporation nor an individual. Justice Sir George Farwell decided that although the union was not a corporation, it was a corporate body, and was therefore liable for payment of damages. Organized labour strongly contested the decision, calling it a direct threat to labour's right to strike. The Court of Appeal in November 1900 revised the decision, but the House of Lords sustained Farwell's opinion on appeal in July 1901. After a hearing in December 1902, the company was awarded £23,000 damages and the total cost to the union was more than £40,000. The House of Lords' decision united labour in an effort to change the law and the Trade Disputes Act of 1906 nullified the effect of the verdict. (A. BRI.)

**TAFILALT** (TAFILET), the largest Saharan oasis of Morocco in the province of Ksar es Souk, lies about 180 mi. (290 km.) S of Fès across the High Atlas Mountains. The oasis (with an estimated population of about 150,000) is a succession of *ksour* (fortified villages) and palm groves, which correspond to the area irrigated by the Oued Ziz and extend over 31 mi. (50 km.). It is famous for its dates; fruits, vegetables, and cereals are also grown. The chief industry is the tanning of goatskins to obtain *filali* leather. Handicrafts include woolen and esparto articles, tiles, and pottery. The main towns are Erfoud, the chief trade centre, and Russani, 13 mi. (21 km.) S of Erfoud.

Sigilmassa (now in ruins) was the old capital of Tafilalt. It was founded in A.D. 757 and soon became a Berber stronghold. Lying on the direct caravan route from the Niger to Tangier, it attained considerable prosperity which it retained until its destruction in 1363. Its *kasbah* was retained by Mulay Ismail (1672–1727) but completely destroyed by the Ait Atta nomads in 1818. The oasis of Tafilalt was first occupied by the French in 1917.

The ruling Filali (Alaouite) dynasty of Morocco, of Arabian origin, settled in Tafilalt in the 13th century and rose to power in the 17th century. The oasis was also used as a place of banishment for the superfluous families of the sultans. (A. AM.)

See W. B. Harris, *Tafilet* (1895).

**TAFT, LORADO** (1860–1936), U.S. sculptor, lecturer, and

teacher, was born at Elmwood, Ill., on April 29, 1860. He graduated from the University of Illinois, Urbana, where he first worked in sculpture, in 1879, and then studied at the École des Beaux-Arts in Paris until 1883, remaining in that city with but brief interruption until 1885. Establishing himself in Chicago in 1886, he taught sculpture at the Art Institute and began his long career of public lecturer. He was elected to the National Academy in 1911. He participated actively in the formation of plans for public education in art, and served (1914–17) as director of the American Federation of Arts.

Aside from many portraits, included among his works are: "Sleep of the Flowers" and "Awakening of the Flowers" for the Columbian Exposition (1893), "Despair" (1898), "Solitude of the Soul" (1900), the colossal "Black Hawk" at Oregon, Ill. (1912), Thatcher Memorial Fountain, Denver, Colo. (1918), and the "Fountain of Time" (1920), intended as part of a monumental complex of sculpture in Chicago.

In 1903 he published *The History of American Sculpture*, the first comprehensive work on the subject. His *Some Modern Tendencies in Sculpture* was published in 1920.

He died at Chicago on Oct. 30, 1936. (J. C. T.; A. T. G.)

**TAFT, ROBERT ALPHONSO** (1889–1953), U.S. senator and four times a candidate for the Republican presidential nomination, was one of the most influential political leaders of his generation. Born in Cincinnati, O., Sept. 8, 1889, he attended the public schools in that city and in Manila, Philippine Islands, where his father, William Howard Taft, 27th president and chief justice of the United States, served as governor-general; he later prepared for college at the Taft School in Watertown, Conn. Serious and scholarly from youth, he was graduated from Yale University in 1910 with highest honours and led his class at Harvard Law School, where he was editor of the *Harvard Law Review*. He passed the Ohio bar examination in 1913.

With his brother Charles and some friends he eventually organized the law partnership of Taft, Stettinius and Hollister. Taft was a brilliant lawyer, specializing in trust and utilities cases, and he also became a director of several successful business enterprises. During World War I he was turned down for military service because of impaired eyesight. He served as assistant counsel for the United States Food Administration, 1917–18, and as counsel for the American Relief Administration in 1919.

Although Taft grew up in politics, his formal apprenticeship as a politician did not begin until 1920 when he was elected to the Ohio House of Representatives. During his three terms in the House (1921–26) he took a keen interest in tax legislation and maintained a staunch party regularity. He served as Republican floor leader in 1925 and as speaker of the House in 1926. In 1930 he was elected to the Ohio Senate, but he was defeated for reelection in 1932. Six years later Taft won election to the U.S. Senate (1938). Entering it early in 1939, when the New Deal policies of Pres. Franklin D. Roosevelt were beginning to encounter strong opposition and the Republican Party was slowly reviving, he lost no time in establishing himself as a powerful influence. A tall, balding, and somewhat ungainly man who wore rimless spectacles and spoke in a harsh, flat voice, Senator Taft hammered away at the "vain, immoral, and dangerous" precepts of the New Deal, denouncing its "socialistic trends," and calling for economy, a balanced budget, and less centralization of power in Washington. Before the Japanese attack on Pearl Harbor he was an outspoken anti-interventionist; after the attack he threw his influence behind the war effort but was critical of Roosevelt's war policies on many occasions.

Taft was reelected to the Senate in 1944 by a narrow margin. But with the end of the war in 1945 and the election of a Republican majority in Congress in 1946, he entered a new phase of power and prestige. He was tireless in his role as chairman of the Republican Senate Policy Committee and well-informed on the legislation before Congress. He made himself the master of the 80th Congress, which Pres. Harry S. Truman denounced as the "worst Congress in history." Taft's most notable legislative achievement was the enactment of the Taft-Hartley Labor-Management Relations Act of 1947, which placed restrictions on

organized labour, and, according to its sponsors, sought to balance the bargaining rights of management and labour. Taft retreated somewhat from the isolationism of his first years in the Senate, but he never became an internationalist and he was too much a partisan to accept wholeheartedly a bipartisan foreign policy. He sponsored social welfare measures in the areas of housing, health, and education, but continued to oppose increased centralization of power in the federal government.

Taft became a candidate for his party's presidential nomination in 1948. He had been Ohio's favourite son candidate at the convention of 1936 and a candidate of national influence in 1940. He came to the convention in 1948 with almost as much support as Thomas E. Dewey of New York, but was unable to prevent the well-organized Dewey group from capturing the nomination. It was a bitter defeat for Taft, who saw himself as the leader of resurgent Republicanism. He disliked the political views of Dewey and his followers, which were more liberal in domestic affairs and more internationalist than the orthodoxy that Taft represented. The election of Harry S. Truman in 1948 set the stage for what was probably the least productive period in Taft's public career, 1949-52. He attacked the Truman administration's China policy and talked of the "pro-Communist administration" and "the betrayal of America at Yalta." He endorsed the anti-Communist campaign of Sen. Joseph R. McCarthy of Wisconsin, but revealed his independence of mind when he said that he doubted whether a college professor should be fired just because he was a Communist.

In 1950 Taft was reelected to the Senate by an overwhelming majority, despite the opposition of organized labour, which condemned the Taft-Hartley Act. The next year Taft announced that he would once more seek the Republican presidential nomination. He campaigned vigorously and went to the convention with almost enough pledged delegates to win the nomination. But it was again denied him when the convention nominated Gen. Dwight D. Eisenhower. Always a strong party man, Taft supported Eisenhower and worked hard for his election.

After Eisenhower's victory, Taft became majority leader in the Senate. He was determined to work effectively with the new president and he quickly became Eisenhower's chief adviser in the Senate. His influence was apparent in many of Eisenhower's major decisions. Then, suddenly, in the late spring of 1953, Taft became seriously ill and on July 31, 1953, he died of cancer. His body lay in state in the rotunda of the Capitol on Aug. 2 and on the following day a national memorial service was held for him. In 1957 the Senate chose him as one of five outstanding senators of the past whose portraits were to be hung in the Senate reception room. The Robert A. Taft Memorial, a carillon tower near the U.S. Capitol, was dedicated in April 1959.

Taft was a superb parliamentarian with extraordinary ability to concentrate upon political and legislative problems. He became the symbol of his party in Congress and was often referred to as "Mr. Republican." His public personality inspired more confidence than affection, in part, it was said, because he tried to appeal to the logic rather than the emotions of his listeners. Walter Lippmann said, "The nation came to rely upon his character as something apart from his politics, and upon the quality of his mind rather than upon his political opinions." In 1914 Taft married Martha Wheaton Bowers, who had a flair for politics and assisted him in his campaigns. They had four sons, one of whom, ROBERT TAFT, JR. (1917- ), also Republican, served in the Ohio legislature from 1955 to 1962, when he was elected to the U.S. House of Representatives. Defeated in his bid for the U.S. Senate in 1964, he was again elected to Congress in 1966.

**TAFT, WILLIAM HOWARD** (1857-1930), 27th president and 10th chief justice of the United States, was born Sept. 15, 1857, in Cincinnati, O., the son of Alphonso and Louise Torrey Taft. His father was U.S. secretary of war and attorney general under Pres. Ulysses S. Grant and later served as minister to

Austria-Hungary and Russia. The younger Taft entered Yale University at the age of 17, graduating with high honours in 1878.

**Early Political Career.**—After two years in the Cincinnati Law School and admission to the Ohio bar in 1880, Taft divided his time between legal practice and politics. In 1887 he was appointed a judge of the Superior Court of Ohio and three years later was named solicitor general of the United States. In that office he won varied and important cases before the U.S. Supreme Court. In 1892 he was named U.S. circuit judge for the sixth circuit, comprising Michigan, Ohio, Kentucky, and Tennessee.

Taft rapidly acquired a reputation for patience, courage, and mastery of jurisprudence. His opinions in various cases relating to disputes between labour and management aroused protests from labour leaders. Though his insistence upon the legal rights of the unions was advanced for his day, he stood firm in his emphasis upon the illegality of the secondary boycott and on the obligation of the courts to enforce their authority and to restrain violence through the power of injunction. That power, however, he utilized also to protect the effective operation of the antitrust laws.

In March 1900 Pres. William McKinley appointed Taft president of the Philippine Commission. To him this summons came as an unwelcome interruption of his judicial career; he accepted it more from a sense of patriotic obligation than because of pressure from Washington. His contribution to the pacification of the Philippines and the organization of their government ranks among the major accomplishments of his career. After rapidly achieving the end of military rule and the establishment of a civil government strong enough to maintain order, he gave attention to the development of the economic wealth of the Islands, construction of roads and harbours, and the education of the Filipinos toward limited self-government. He gained a spectacular success in the settlement of the delicate issue concerning the ownership of church lands taken over by the Filipinos from Roman Catholic friars.

On two occasions during his service in the Philippines, of which he became civil governor in July 1901, Taft was invited to become a justice of the United States Supreme Court. In declining, he sacrificed personal ambition to the claims of conscience in completing his mission in the Islands. In January 1904 Pres. Theodore Roosevelt recalled him to the U.S. to become secretary of war. Taft accepted the appointment with the stipulation that he would continue in close supervision of Philippine affairs.

As a member of the Cabinet he successfully undertook assignments far beyond the scope of routine duties. He became the troubleshooter of the administration, serving actually as executive assistant to the president, and earned a reputation both as mediator and administrator. He was primarily responsible for the appointment of Maj. George W. Goethals as chief engineer of the Panama Canal and for the reorganization of the construction program that made possible its opening in 1914. Sent to Cuba in 1906 in the face of impending revolution, he effected a peaceful and successful settlement. During the same year he devised and supervised the measures taken to cope with the hardships that had resulted from the San Francisco earthquake and fire.

Such achievements gave Taft a preferred position as the Republican candidate to succeed Roosevelt as president when Roosevelt made clear his determination not to seek reelection in 1908. Taft's position was also strengthened because he was the president's choice. Taft had previously indicated a distaste for the presidency, but he was persuaded to change his mind by his wife and other supporters. At the Republican convention in 1908 Taft was nominated on the first ballot and James S. Bulloch of New York was nominated as his running mate. On Nov. 3 of that year he was elected president, gaining 321 electoral votes to Democrat William Jennings Bryan's 162 as well as a popular plurality of more than 1,000,000.

**President.**—Taft's triumph at the polls could not conceal a smooth away the difficulties that stemmed from a growing division within the Republican Party. He failed to recognize the power of the progressive, less conservative faction and included none of its members in his cabinet. Faithful to his platform promises, he determined to force a settlement of the tariff issue and, with more honesty and courage than political acumen, to

called a special session of Congress in an attempt to satisfy the demand for a reduction in duties. Congress, influenced by conservative Republican Sen. Nelson Aldrich, passed the Payne-Aldrich Tariff Act, which provided for only a limited reduction. Taft angered the Republican progressives by refusing to veto the bill.

In spite of the disunity in Republican ranks and the growing strength of the Democrats, whose election victory in 1910 gave them control of the House of Representatives, the unspectacular achievements of Taft's administration served the cause of good government. The president sponsored federal economy and took steps toward the formation of an annual budget; he established the federal postal savings system; the impetus he gave to the conservation of natural resources was notable, although obscured by a controversy over public lands between Secretary of the Interior Richard Ballinger and forestry bureau chief Gifford Pinchot; his enforcement of the antitrust law was vigorous. Two of Taft's proposals in which he took special interest failed completely. The treaties of arbitration with Great Britain and France were so grossly amended by the Senate that he withdrew them; the tariff agreement with Canada, for which, with great difficulty, he won congressional approval, was ultimately rejected by Canada.

The last months of Taft's administration were clouded by a quarrel with Roosevelt that culminated in the disruption of the Republican Party. The president was shocked by the increasing radicalism of his predecessor. Roosevelt, impatient with what he regarded as Taft's inflexible conservatism, determined to contest the nomination for the presidency in 1912. On the first ballot the Republican convention gave a clear majority to Taft. Contending that the national committee had "stolen" sufficient votes to win in the convention, Roosevelt proceeded to organize his followers into the Progressive Party (also known as the Bull Moose Party) with himself as nominee. The Republican split guaranteed Wilson in November to the Democratic candidate Woodrow Wilson, who received 435 votes in the electoral college, to 88 for Roosevelt, and 8 for Taft. The popular vote stood at Wilson, 6,291,454; Roosevelt, 4,119,538; Taft, 3,484,980. Taft's running mate, Sherman, died on Oct. 30, a few days before the election. Taft found a satisfying harbour of retirement from the presidency in his appointment as Kent professor of law at Yale. In 1914 he was appointed to the National War Labor Board by President Wilson. He was a promoter of the League to Enforce Peace and a strong supporter of United States participation in the League of Nations. On the death of Chief Justice Edward White in 1921, Warren G. Harding appointed Taft to his place.

**Chief Justice.**—Taft officially assumed the functions of chief justice on Oct. 3, 1921. He found the court far behind in its work and promptly took steps to improve the efficiency of its judicial machinery. His influence was decisive in securing passage of the Judges Act of 1925, which enabled the Supreme Court to exercise wider discretion in its acceptance of cases and allowed it to give precedence to those of national importance. He labored incessantly and successfully to keep the court's docket clear.

The opinions of Taft as chief justice were popularly regarded as conservative as they affected labour disputes as bearing out his reputation for conservatism, but actually they illustrated his inclination to take a middle-of-the-road position. His approval of use of court injunctions was limited by his insistence that injunctions not be employed to interfere with the right of workers to organize and strike. His constitutional opinions generally indi-

THE GRANGER COLLECTION  
WILLIAM HOWARD TAFT. PHOTOGRAPHED IN 1908

cated his suspicion of innovations. In the Child-Labor case (1922) in which he was sustained by all but one of his colleagues, he made clear his conviction that to permit Congress to utilize its taxing power for the promotion of social reform, however desirable, would "completely wipe out the sovereignty of the states." In the Myers case (1926), however, he rendered an opinion greatly widening the power of the president to remove executive officers—an important contribution to constitutional law.

In the field of commerce Taft displayed tendencies less conservative than generally expected. He supported broad federal powers under the interstate commerce clause of the Constitution. His outstanding dissent placed him on the liberal side in opposition to the majority opinion that invalidated the law of 1918 fixing a minimum wage for women in the District of Columbia. The law in question, Taft insisted, dealt with the public interest in that sweatshop wages did as much to impair health and morals as did long hours; because of this the law in his judgment was constitutional.

Taft's service as chief justice brought him deep satisfaction, and he served in that office for almost nine years. His health, which had weakened after a heart attack in 1926, deteriorated rapidly early in 1930. On Feb. 3, he sent his resignation to Pres. Herbert Hoover. He died in Washington, March 8, 1930, and was buried in Arlington National Cemetery.

Taft was married June 19, 1886, to Helen Herron of Cincinnati. They had three children: Robert Alphonso Taft (q.v.), U.S. senator (1939–53); Helen Herron Taft (Mrs. Frederick J. Manning), dean and professor of history at Bryn Mawr College (1926–57); and Charles Phelps Taft, lawyer, author, and mayor of Cincinnati (1955–57).

**TAGALOG**, the second largest ethnolinguistic group in the Philippines (after the Cebuano), numbered about 4,000,000 in the 1960s, and form the dominant population in the following areas: all provinces bordering Manila Bay except Pampanga; Nueva Ecija to the north; Batangas, Laguna, Marinduque, Mindoro, and Quezon to the south; and the city of Manila. The high Tagalog literacy rate is estimated at 70%; their Malayo-Polynesian language is closely related to Bisayan and Bikol (q.v.).

Next to English the most widely read and spoken tongue in the Philippines, Tagalog is by law the national language, and is a required school subject. However, English remains the language of government, business, instruction, and most of the press, sharing with Spanish and Tagalog the status of an official language.

Most Tagalog are farmers whose *sitios* (small hamlets) aggregate with surrounding farmland into barrios similar to U.S. townships. Most rice is grown in flooded, diked fields, but is produced dry in many upland areas. Almost all rice is locally consumed, but the other principal crops, sugar and coconut, are mainly for export. The importance of Manila has given the urban Tagalog leadership in local and overseas commerce, finance and manufacture, in the professions, and in clerical and service occupations, producing a most influential middle class. Because of Manila, the Tagalog served as primary mediators of more than 500 years of Chinese, Spanish, and U.S. influence, selecting from, interpreting, and adapting these foreign cultures to the basic Indo-Malayan social pattern. They have thus led in the modernization and westernization that has passed in varying degrees to all parts of the archipelago.

However, the Tagalog have sharply resisted alien economic and political control. They imitated the anti-Spanish propaganda movement of the 19th century and their generals led in armed revolts against Spain and the U.S. (1896–99). The principal national heroes of this period (José Rizal y Mercado, Andres Bonifacio, Apolinario Mabini, and Emilio Aguinaldo) were Tagalog. Tagalog were among the leaders in the subsequent achieve-

ment of Philippine independence by constitutional means (see PHILIPPINES, REPUBLIC OF THE: *History*).

More than 80% of the people in the Tagalog provinces are Roman Catholic; about 7% are members of the Philippine Independent (Aglipayan) Church, and about 3% are members of the several Protestant churches; Freemasonry is strong among them.

See C. Kaut, "Utang Na Loob: A System of Contractual Obligation Among the Tagalogs," *Swest. J. Anthropol.*, vol. 17 (1961); A. Ruñño, *A Handbook of Tagalog Grammar* ... (1963). (E. D. H.)

**TAGANROG**, a town and seaport of Rostovskaya (Rostov) Oblast' of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the northern coast of Taganrogskiy Zaliv (Taganrog Gulf) of the Azovskoye More (Sea of Azov). Pop. (1959) 202,062. Founded in 1698 on an earlier site as a naval base and fortress, it developed in the 19th century as a major grain exporting port. Heavy industry is of great importance, producing steel, welded and solid-drawn pipes, steam boilers, combines, and machine parts. There are also leather working and fish processing. The town has radiotechnological and pedagogic institutes. The author Anton Chekhov was born at Taganrog, and his house is preserved as a museum. (R. A. F.)

**TAGLIONI, MARIE** (1804–1884), Swedish-Italian ballerina whose ethereal lightness and poetic imagination made her dancing a symbol of the Romantic era, was born in Stockholm on April 23, 1804. She studied under her father, FILIPPO TAGLIONI (1777–1871), a distinguished ballet master who created for her his masterpiece *La Sylphide*, which has been called the first Romantic ballet. Taglioni made her debut in Vienna in 1822 and appeared at the Paris Opéra five years later. She attracted favourable attention in D. F. E. Auber's *Le Dieu et la bayadère*, Meyerbeer's *Robert le Diable*, and Rossini's *William Tell*, in which the "Tyrolienne" was composed especially for her. In 1832 her triumph in *La Sylphide* established her supremacy as the first ballerina of Europe. Her position was seriously challenged in 1836 by the Austrian Fanny Elssler (*q.v.*), whose fire and voluptuousness were in direct contrast to Taglioni's classicism. Taglioni soon withdrew from the contest, accepting lucrative engagements in Russia and England. In London, in 1845, she appeared with Carlotta Grisi, Fanny Cerrito, and Lucile Grahm in Perrot's celebrated *Pas de quatre*. She retired in 1847 but lived to the age of 80, dying on April 24, 1884, at Marseilles.

Taglioni married Count Gilbert de Voisins in 1832, but the marriage was soon dissolved. Her brother PAUL TAGLIONI (1808–84) was also a dancer and choreographer and ballet master at the Berlin Opera, where for many years his daughter, MARIE TAGLIONI the younger (1833–91), was ballerina.

See André Levinson, *Marie Taglioni* (1930).

(LN. ME.)

**TAGORE, DEBENDRANATH** (1817–1905), Indian philosopher and religious and social reformer, known as Maharshi, ("Great Sage" or "Seer"), combined intellectual aristocracy and saintly eminence with a practical zeal for educational reform, national liberation, and the reinstating of India's monotheistic religious traditions. He was born at Calcutta on May 15, 1817, the eldest son of Prince Dwarkanath Tagore (1794–1846). Dwarkanath Tagore, a rich landowner, had given financial support to Ram Mohun Roy's Brahmo Samaj (*q.v.*), and Debendranath Tagore succeeded Ram Mohun as leader of the movement, carrying on the founder's efforts to reform Hinduism and purify it of the excrescences it had accumulated over the many generations since the Vedic period. He emphasized the nondualistic aspect of Vedic philosophy, while stressing ethics and service as leading to direct experience of God.

Debendranath's formal education began when he was 9, at the Anglo-Indian School established by Ram Mohun, and was continued at Hindu College till he was about 17; his school years were merely a prelude to a long life of arduous self-education. He frequently visited pilgrimage places in the Himalayas, and he learned from the scholars of the northern as well as the southern regions of India. Among his achievements was the establishment of the Tattvabodhini Sabha ("Society" or "Meeting House for the Awakened Knowledge of Truth") and of the journal issued by this group. In 1886 he founded, as a retreat in rural Bengal, Santini-

ketan ("Abode of Peace"), later made famous by his son the poet Rabindranath Tagore (*q.v.*), who built there an educational centre, now an international university. Debendranath Tagore died at Calcutta on Jan. 19, 1905.

All of his publications were in Bengali except for a small book, *Vedantic Doctrines Vindicated* (1845), which contained English translations of some of his answers to critics of Indian thought. His scriptural anthology, *Brahmo-Dharma* ("The Religion of God"), incorporating Sanskrit texts mainly from the Vedas, the Upanishads, and the Bhagavad Gita, along with his Bengali translations and interpretive notes, was published in 1854.

**BIBLIOGRAPHY.**—*Autobiography of Maharshi Devendranath Tagore*, Eng. trans. (1909); Krishna Kripalani, *Rabindranath Tagore*, chapter on the poet's family background (1962); R. C. Majumdar and others, *An Advanced History of India* (1950). (AM. C.)

**TAGORE, RABINDRANATH** (1861–1941), Bengali poet and mystic, who won the Nobel Prize for Literature in 1913, was born in Calcutta on May 7, 1861. The youngest of the 14 children of the "Great Sage" (Maharshi) Debendranath Tagore (*q.v.*), he received his real education at home. He early began to write verses, and, after several books of songs in the 1880s, in 1890 published *Mānasī*, a collection that marks the maturing of his genius. It contains some of his most famous poems, including many in verse forms new to Bengali, among them the ode. It also contains his first social and political poems.

In 1891 he went to manage his father's estates in Shileida (Śilāidāh) and Sayadpur. He lived there in close contact with village folk, and his sympathy for their poverty and backwardness was the keynote of much later writing. Stories "on humble lives and their small miseries" were collected in *Galpa Guccha* ("Bunches of Tales," 1912). He also became interested in political and social problems, and supported the *svadeśī* campaign, although never regarding independence as an end in itself. At Shileida too he came to love the Bengali countryside, most of all the River (the Ganges), perhaps his most oft-repeated image. During these years he published several collections—*Sonār Tori* ("The Golden Boat," 1893), *Chitrā* (1896), *Chaitālī* ("Late Harvest," 1896), *Kāpanā* ("Dreams") and *Kṣanikā* (both 1900), *Naivedya* ("Offerings," 1901)—and two lyrical plays: *Chitrāngadā* (1892; Eng. trans. *Chitra*, 1913), in blank verse; and *Mānāsī* (1895).

In 1901 Tagore founded a school at Santiniketan, near Bolpur; there he sought to blend the best in the Indian and Western traditions. Years of sadness (his wife and a son and daughter died between 1902 and 1907) inspired some of his best poetry. His most famous collection, *Gitānjālī*, was published in 1910. An English collection under the same title won him the Nobel prize; and he was awarded a knighthood in 1915. The latter he surrendered in 1919 as a protest against the Amritsar massacre (see INDIA-PAKISTAN, SUBCONTINENT OF: *History: British Imperial Administration*).

He continued to publish songs and poems: between 1916 and his death he published 21 collections. Much of his later life was spent in lecture tours in Europe, the Americas, China, Japan, Malaya, and Indonesia. Many of his works were translated into English, by himself and others, but the English versions fall far below the Bengali originals. His novels, although less outstanding than his poems and short stories, are worthy of attention; the most famous is *Gorā* (1910; Eng. trans., 1924).

In 1924 Tagore inaugurated the Visva-Bharati University at Santiniketan, as an all-India and international centre of culture. He died at Calcutta on Aug. 7, 1941.

See E. Thompson, *Rabindranath Tagore: Poet and Dramatist* (1926; rev. ed. 1948); K. Kripalani, *Rabindranath Tagore* (1962), with bibliography of works in English. (T. W. C.)

**TAGUS** (Portuguese TEJO; Spanish TAJO), the longest river of the Iberian Peninsula (625 mi. [1,006 km.]), rises about 110 mi. (177 km.) from the Mediterranean and flows west into the Atlantic Ocean. Its drainage basin of 31,159 sq.mi. (80,701 sq.km.) is exceeded by that of the Ebro. Compared with rivers of similar length, the Tagus has relatively few tributaries (59); all the important ones come from the north and, rising on steep im-

pervious mountain slopes of granites or schists, contribute greatly to frequent and violent floods. The asymmetry of its valley floor, pushed southward by the right-bank tributaries, and the meagre flow of the left-bank streams are explained by the mountain ranges. Northward the horizon is dominated by the high mountains of the Somosierra, Guadarrama, Gredos, and Gata extending into Portugal as the Estrêla, Lousã, and Aire. To the south lie the mountains of Toledo and Guadalupe and the dry featureless plateaus of La Mancha and Extremadura.

The Tagus rises at 5,250 ft. (1,600 m.) on the borders of the Montes Universales (Cerro de San Felipe) and swings southwestward near the holiday resort of Trillo until near Aranjuez it is joined on the north bank by the Jarama, the largest tributary of its upper course (50 cu.m. per sec.). From there the Tagus flows almost due west into Portugal, keeping to the southern borders of the broad tectonic trough and, in places (e.g., Toledo), cutting through epigenetic defiles. Joined by its north-bank tributary, the Alagón, near the international frontier, it follows a series of gorges. At Constância it is joined by the Zêzere (*q.v.*), its greatest tributary, which increases its average flow to 460 cu.m. per sec. After this confluence it swings southwest to the sea. No other European river has surpassed its record of December 1876, when its flow was 15,850 cu.m. per sec.

In the Spanish basin of the Tagus, 19 dams were under construction in the 1960s on tributaries and one on the upper Tagus at Entrepeñas. The largest is at Buendia, on the Guadiela, which generates almost half of the total hydroelectric power of 591,600,000 kw-hr. About 70,000 ac. (28,000 ha.) are irrigated, especially on the Tagus near Aranjuez and on the Jarama and Henares; there were plans for the eventual irrigation of a total of 700,000 ac.

Small boats can reach Vila Velha de Ródão, Port., but in practice Santarém is the commercial limit of navigation, and then only when conditions are favourable. At Lisbon the estuary widens into the three-mile-wide Mar de Palha, which is tidal and therefore little affected by the marked irregularity of the river's flow.

(J. M. Ho.)

**TAHITI**, the largest and most important of the Windward Group and of the Society Islands, part of French Polynesia (*q.v.*), lies in the central South Pacific Ocean in latitude 17°40' S and longitude 149°22' W. It is of hour-glass shape, oriented northwest-southeast, with the larger portion called Tahiti Nui and the smaller Tahiti Iti, or Taiarapu; both portions are connected by the isthmus of Taravao. The island is about 33 mi. (53 km.) long and has an area of about 388 sq.mi. (1,005 sq.km.). Papeete (*q.v.*) is the capital and administrative centre of the island and of French Polynesia.

**Physical Geography.**—Tahiti consists of two ancient volcanic cones with secondary peaks, deeply dissected by valleys, and is surrounded by a coral reef lying from  $\frac{1}{2}$  to 2 mi. off shore. Orohena, the cone of Tahiti Nui, rises to 7,618 ft. (2,322 m.), with a lesser peak Aorai 6,788 ft. (2,069 m.); Roniu on Tahiti Iti is 4,341 ft. (1,323 m.). A narrow fertile plain surrounds the mountains, through which short, straight rivers, seasonally torrential, enter the lagoon. There is a high mountain lake, Vaihiria.

Lying in the easterly trade winds belt, Tahiti has clearly marked wet and dry sides with annual average rainfalls of 106.7 in. (2,710 mm.) and 72.3 in. (1,836 mm.); the greatest amount falls from December to March. Temperatures are high, varying from an average of 24° C (76° F) in July and August to 29° (84°) in January and February. Vegetation includes coconut palms, pandanus, lantana, hibiscus, and fruit trees.

**People and Population.**—The Tahitians are Polynesians who arrived from another of the Society Islands, Raiatea, a Polynesian cultural diffusion centre. On Tahiti they developed political districts, closely connected with a graded system of rank and authority, resting on the extended family organized around the temple. The high chiefs (*arii nui*) exercised considerable authority, supported by supernatural sanctions and a priesthood, but their relationship with lesser chiefs and people was reciprocal. This society disappeared under European impact, and intermarriage and the French policy of assimilation produced a people basically

FRED LYON—RAPHO GUILLUMETTE

BOATS TIED UP ALONG THE QUAY BORDERING THE MAIN STREET OF PAPEETE, CAPITAL AND CHIEF TOWN OF TAHITI

Polynesian, though with much admixture of other blood and deeply influenced by French culture (*see also* POLYNESIA).

The population, which declined after the first European contact, is increasing. The total population in 1962 was 45,430; of the total of 36,325 in 1956, 28,867 were French of Oceanic origin, 2,057 were French, 5,072 were Chinese (originally brought as labourers), and there were 329 others.

**History.**—The first European to discover Tahiti was Capt. Samuel Wallis in 1767; later visitors included L. A. de Bougainville (1767), Capt. James Cook (*q.v.*; 1769, 1773, 1777), and Lt. William Bligh (1788). The first permanent European settlers were members of the London Missionary Society who went to Tahiti in 1797 to settle at the usual anchorage, Matavai Bay. Their influence, and that of European muskets supplied by other settlers and visitors, raised the prestige of the local chiefly family of Tu or Pomare, who aspired to achieve supreme power over the whole island. Pomare II (1803–24) embraced Christianity in 1812. Three years later, with the support of the Europeans, he triumphed over other Tahitian chiefs and established a "missionary" kingdom with a scriptural code of law. Under Pomare III (1824–27) and Queen Pomare IV (1827–77), a reaction by Tahitian rivals, the effects of disease, prostitution, and drunkenness, and the influence of European traders and beachcombers challenged the missionaries' hold. In 1836 French Roman Catholics attempted to open a mission in Tahiti, but Queen Pomare, on the advice of the English missionary and consul, had the two French priests deported. This brought a French frigate under the command of Abel Dupetit-Thouars in 1842 to demand reparations and to arrange a French protectorate; the protectorate became essentially a naval government of limited effect and weak finances and had virtually ceased to work by 1880, when Pomare V (Queen Pomare's son) abdicated and Tahiti was proclaimed a French colony.

**Administration and Social Conditions.**—Civil administration was set up by the Organic Decree of 1885. Tahiti was divided into districts, each under a chief and an advisory council, but authority really rested with the French and, very often, with the pastor of the Tahitian Protestant Church. After World War II, during which Tahiti adhered to the Free French movement of Gen. Charles de Gaulle, an elected representative or territorial assembly was set up in French Oceania, and in 1957 a council of government was added. All Tahitians (who had been French nationals since annexation) became French citizens in 1945. In 1958 Tahiti voted to remain within the French Community.

Education is shared by government and subsidized mission schools. Health conditions are generally good; there is no malaria, but mosquitoes carry elephantiasis. Tuberculosis is the main hazard. Government hospitals exist at Papeete and other centres, with dispensaries elsewhere. A French subsidy provides social services. (See also FRENCH POLYNESIA.)

**Economy.**—Agriculture is the main occupation, with copra as the chief export. Although copra does not provide sufficient trade, most Tahitians can support themselves easily on garden produce and on fish, which are plentiful. The livestock includes pigs, horses, cattle, and fowl. Retail trade and market gardening are dominated by the Chinese settlers.

There is a good coastal road around Tahiti, and interisland traffic is maintained by small vessels. Several shipping services on the Los Angeles-Sydney route call at Papeete. The island is also linked by air with Paris, Honolulu, and New Zealand.

**TAHMASP I** (1514–1576), Safavid shah of Persia from 1524 to 1576, was born in the village of Shahabad, near Isfahan, on March 3, 1514. He was the eldest son of Shah Ismail I (q.v.), whom he succeeded in 1524. The young monarch was for long a pawn in the hands of the Kizilbash tribal leaders, and his early years as shah were troubled by repeated incursions of the Uzbeks and by local uprisings. In 1534 the Ottoman Turks, under Suleiman I the Magnificent, attacked Persia, taking Tabriz, the Persian capital, and recovering territory in Mesopotamia that Shah Ismail had wrested from them. In 1538 the Turks again invaded Persia, taking Tabriz a second time. Driven from his country by a revolt, the Mughal emperor Humayun in 1542 took refuge at Tahmasp's court. Tahmasp later lent him troops for the recovery of his kingdom. Five years later a serious situation developed when Ilkhas Mirza, the shah's brother, rebelled and threw in his lot with the Turks. In the war which ensued Tabriz was once again lost; though it was soon regained, its vulnerability led Tahmasp to move his capital to Kazvin. Peace was concluded between Persia and Turkey in 1555. In 1561 the Englishman Anthony Jenkinson arrived at Tahmasp's court bearing a letter from Queen Elizabeth, his object being to establish trade between Persia and England across Russia. Tahmasp at first received him with courtesy, but bade him depart when he found that he was a Christian.

In Tahmasp's long reign the decorative arts became highly developed and the shah himself achieved some distinction as a painter and calligraphist. In his later years Tahmasp secluded himself in his palace, paying little attention to public affairs; he thus allowed the turbulent tribal leaders to increase their power, while the Uzbeks renewed their inroads on the northeastern provinces. When Tahmasp died (probably at Kazvin) in 1576 he left Persia appreciably weaker than it had been at his accession; on the other hand, he had succeeded in keeping the redoubtable Ottoman Turks in check. **TAHOE, LAKE**, a freshwater lake occupying a fault basin on the California-Nevada boundary in the northern Sierra Nevada, fed by numerous small streams and drained by the Truckee River to Pyramid Lake, Nevada. It measures 22 mi. (35 km.) north-south and 12 mi. east-west; its surface stands at 6,229 ft. (1,899 m.) above sea level and its maximum depth is 1,640 ft. (500 m.).

Numerous camps, lodges, and motels cater to summer tourists attracted by the scenery (snowy peaks rising above coniferous forests), water sports, and trout fishing, and to winter sports enthusiasts. (R. F. Ln.)

**TAI CHEN** (TAI TUNG-YÜAN) (1724–1777), Chinese historical geographer, philologist, and empirical philosopher, considered

by many scholars to have been the greatest thinker of the Ch'ing period, leading figure in the movement called "Investigations Based on Evidence," was born at Hsiu-ning, Anhwei Province, on Jan. 19, 1724, of poor parents. He educated himself by reading borrowed books, and then, becoming acquainted with the scholar Chiang Yung, studied mathematics, philology, and the *Record of Rites* with him. Later he was invited by the emperor Ch'ien-lung (q.v.) to serve as one of the court compilers of the *Ssu-k'u ch'üan-shu*, the Imperial Manuscript Library. In this project Tai was exposed to many rare and otherwise inaccessible books.

Altogether Tai wrote, edited, and collated about 50 works, dealing mainly with mathematics, philology, ancient geography, and Confucian classics. In mathematics, he wrote the *Ts'e-suan*, a short discourse on Napier's rods (see NAPIER, JOHN); and edited a collection of seven ancient mathematical works, the last of which is his own collation. In philology, he completed two works, the *Sheng-lei-piao*, a classification of ancient pronunciation; and *Sheng-yün-k'ao*, miscellaneous notes on phonology. Tai's collation of the 3rd-century-B.C. classic *Shui-ching-chu*, a study of 137 waterways in ancient China, which he prepared on the basis of a rare edition in the Imperial Manuscript Library, incited controversy during his life and after his death. Some scholars doubted whether he ever had access to the Imperial Manuscript Library edition, others charged him with plagiarizing a work produced earlier by Chao I-ch'ing. Most modern scholars agree with Hu Shi's conclusion that the work is unquestionably Tai's collation.

Perhaps Tai's greatest contribution to Chinese thought lies in the field of philosophy. Since the rise of neo-Confucianism during the Sung period, man had been believed to have a dual nature; a material one responsible for his passions, feelings, and desires, and a spiritual endowment which derives from Heaven-will and is therefore basically good (see CONFUCIANISM; CHINESE PHILOSOPHY). Scholars before Tai Chen had attempted to refute this philosophy, but he was one of the very few who spoke out strongly against its futility, absurdity, and impracticability. He believed in the ever-presence of desires, feelings, emotions, and evil propensities; the only sure way to undermine their influence is an arduous quest for truth—truth attained by exactness, objectivity, and precision, whether it be literary, historical, philological, or philosophic. Meditation as practised by Sung philosophers is not pragmatic; search for incontestable evidence through textual criticism, on the other hand, is crucial.

Because he had no devoted followers, Tai's philosophy was not pursued during the first 100 and more years after his death on July 1, 1777. Thanks to its closeness to Western thinking, however, his work began to be appreciated by returned students from abroad, and in 1924 the bicentennial of his birth was celebrated in Peking under the joint sponsorship of Hu Shih and Liang Ch'i-ch'ao. In 1936 the Chinese scholarly world paid tribute to Tai Chen with the publication of a complete and authoritative edition of his works, *Tai Tung-yüan hsien-sheng ch'üan-chi*.

No detailed study of Tai Chen is available in English. For general information, see Arthur W. Hummel, *Eminent Chinese of the Ch'ing Period*, vol. ii, pp. 695–700 (1944); for his philosophy, see Wing-tsit Chan, *A Source Book in Chinese Philosophy*, pp. 709–722 (1963). (Y. T. W.)

**TA'IF, AT**, a city and summer capital of Hejaz (q.v.), Saudi Arabia, lies at an altitude of over 5,000 ft. (1,520 m.), about 40 mi. (64 km.) ESE of Mecca with which it is linked by road. Pop. (1963 est.) 54,000. Once the seat of the pagan goddess Allat, it is revered now for the tomb of 'Abadullah ibn Abbas, cousin of the Prophet Mohammed, and for the graves of two infant sons of the Prophet. The royal palace and airport are at Al Hawiyah, 20 mi. N. The central commercial area of At Ta'if preserves the Wabhabi fort of the early 19th century, but the suburbs have been expanded and modernized. The surrounding gardens produce a variety of fruits, with pomegranates and grapes predominating. The water supply was improved by building the 'Ikrima dam and a dam across the Wadi Mahram to the northwest.

(H. St. J. B. P.; X.)

**TAI LANGUAGES.** The Tai languages form an important branch of the Sino-Tibetan language family, which also includes Tibeto-Burman and Chinese (see SOUTHEAST ASIAN LANGUAGES).

They are spoken by more than 30,000,000 people in a vast area stretching from south China through Laos and Thailand to the Malay Peninsula, and from Assam in India through the Shan States of Burma to the highlands of North Vietnam and to Hainan Island.

Tai languages are remarkably homogeneous. Although their mutual intelligibility is limited, many differences are merely dialectal. The best-known member of the group is the national language of Thailand, Central Thai or Siamese, which is based on the dialect of Bangkok and the central plain (see THAI LANGUAGE). The major dialect areas of Thailand are central, northern (Yuan or Kammüang), northeastern (Lao), and peninsular. However, the dialects of Thailand are not easily classified in an absolute manner. Mutually exclusive sets of characteristics overlap the boundaries of subgroups in a complex way. Neither do dialectal and national boundaries coincide. The northeastern dialects of Thailand are to be classed with those spoken in the greater part of Laos. The northern dialects of Thailand have important characteristics in common with Shan and certain dialects of southern China and northern Laos such as Lü. The present-day position suggests that there has been a long history of population movement and contact, explained in part by the southward migrations of the Thai peoples.

Most of the Tai dialects of south China are classified by the Chinese linguist Fang-Kuei Li into two further groups on the basis of phonological and lexical criteria.

Tai languages have many Sinitic characteristics. They are isolating, monosyllabic, and noninflective. Syllabic structure is relatively simple, consisting of initial consonant(s) plus vowel with the possibility of syllabic closure by a strictly limited range of continuant or stop consonants. Like Chinese, Tai languages are tonal in the sense that an important determinant of lexical meaning is the pitch or contour tone on which the word is pronounced. Among dialects, there are five to seven distinctive tones. Word order is an important grammatical feature.

Despite the Sinitic character of Tai, many of its speech-groups have come into contact with Indian civilizations, partly through the ancient Mon and Khmer empires (see below). Thai (Siamese) and Lao are particularly rich in borrowings from Mon-Khmer and Indic languages. The Indian Sanskrit and Pali, though genetically distinct from Tai, are recognized as classical languages by the Siamese and Lao peoples because of the deep-seated Hindu and Buddhist cultural influence among them. Neologistic Sanskrit derivatives are preferred to Western borrowings for modern technical vocabulary. The Indic connection has provided Siamese and Lao with many polysyllabic forms. Shan is heavily affected by borrowing from Burmese, and Black and White Tai by Vietnamese.

The script tradition is ultimately Indian. The earliest known writing systems are those of the period of the Sukhothai kingdom (13th-14th centuries A.D.). Sukhothai, in north-central Thailand, lay between the Indianized Mon and Khmer states, and the scripts of these peoples are the proximate origin of Sukhothai writing, from which have developed the scripts used in Thailand and Laos, and by Thai peoples in North Vietnam. Shan and certain other Tai languages of Burma and south China use scripts derived from Burmese, which is also Indian-based. Romanized scripts were introduced for some previously unwritten Tai dialects of southern China after 1949.

**TAILLE**, the direct tax from which the French kings of the ancien régime derived the major part of their revenue; it weighed intolerably upon those liable to it. Although essentially a royal tax, the taille was seigneurial in origin and retained that characteristic until the mid-14th century.

The earliest form of the taille was the request for goods, money, or labour services that the decline of slavery in the 10th century forced landlords to make of their tenants. From the 11th century, as an annual payment due from all the inhabitants of a seignior except the clergy and the nobility, it was called *servitium*, *tallia*, *incisura* (the two latter words deriving from the notch or mark made on the collector's tally, or from the portion deducted from the wages of the taxpayer, or *focagium* [French, *fouage*, *feux*, the hearth]). The total sum required by the lord was apportioned among those liable according to their means; it was payable in installments. From the 13th century the amount due had sometimes become fixed by the custom of the manor; this was the *taille abonnée* or *taille jurée*.

The seigneurial taille which the king, like other landowners, raised from his demesne, developed as a result of the heavy expenses of the Hundred Years' War into the royal taille, levied throughout the land. For this reason its proceeds were thereafter classified as extraordinary revenue, as opposed to that derived from the royal demesne alone. At first levied (as in 1314) on their tenants by the ordinary landowners as an extra subsidy for the crown's benefit, this tax became in due course a genuinely royal taille, collected by the king's agents. The doctrine that this was a tax which the king alone could impose was first formulated in 1412; in 1439 both landlords and town authorities were forbidden to levy it without royal authorization. King Charles VII laid down the method and scales for its collection in a series of ordinances (1445-59) at the time when, along with the companies of mounted men-at-arms and the *francs archers* (*franc*, free, because exempt from the taille), the first standing armies were raised. Nevertheless the Estates General of 1484 denounced the taille as a wartime tax unjustifiably continued in time of peace.

From that time until the Revolution the taille was the subject of innumerable regulations designed to extract from it the maximum return and to establish more equitable assessment. The *tallion* or *crue de taille*, a supplement for the payment of troops, was added in 1549, and a repartition was carried out in the 17th century.

Taille was collected in two ways. In the districts of the *taille personnelle* (i.e., the north of the kingdom), it was levied on an individual basis; in the districts of the *taille réelle* (i.e., Guienne, Dauphiné, Languedoc, and Provence) it was levied on workers' land in the country districts and on businesses in the towns. In the first areas lists of those liable had to be drawn up; in the second the registers of land values had to be constantly revised. There was also another distinction. In the *pays d'élection* (districts without provincial estates and usually corresponding to the dioceses) taille was apportioned and collected by the *élus*, royal officials first established in the 14th century. But in the *pays d'état* (Brittany, Burgundy, Languedoc, Dauphiné, and Provence) the total amount was agreed upon by the estates of the respective provinces, under the fiction of a free gift. For the former the amounts required from each district were fixed and, at the parish level special assessors, appointed by the taxpayers, apportioned these amounts between the hearths or households.

Those exempt from taille in the 18th century included not only clergy and nobles who had never been subject to it, but also the inhabitants of most large towns. Exemptions (resulting, for instance, from the multiplication of ennobling offices in the judiciary and finance departments) increased steadily, leaving an even more intolerable burden on those who remained liable. The rate was also constantly raised, and it is estimated that the taille brought in 64,000,000 livres in 1780 and nearly 90,000,000 in 1789. It was abolished at the Revolution.

**TAILORING:** see CLOTHING MANUFACTURE.

**TAIN**, a royal and small burgh in the county of Ross and Cromarty, Scot., near the southern shore of Dornoch Firth, 26½ mi. NE of Dingwall by road. Pop. (1961) 1,699. The name is from the Icelandic *thing* (assembly). It is the centre of a prosperous agricultural area specializing in raising and exporting seed potatoes (mainly to England) and in rearing the valuable Calrossie short-horn cattle. There are well-known golf links. Anciently Tain was a place of sanctuary, the "Immunity of Tayne" being marked by four crosses, but the privilege was violated in 1306, when the earl of Ross abducted Robert Bruce's wife and daughter and handed them over to Edward I, and again in 1427 when McNeille of Creich burned the chapel of St. Duthac (Duthus) of which there are remains near the railway station. The church of St. Duthus was built by the bishop of Ross in 1370. In 1487 it became collegiate, the alteration being confirmed by a papal bull still preserved by the corporation. The building was used as the parish church until 1815 when it fell into disrepair, but it was restored in 1871–76. Three and a half miles southeast are the remains of the abbey of Fearn, founded at Edderton in 1230 by Farquhar, 1st earl of Ross, and transferred there in 1338.

**T'AI-NAN** (Japanese TAINAN), a city on the southwest coast of Formosa (Taiwan). Pop. (1964 est.) 393,000. It was an early settlement of Chinese emigrating from Kwangtung and Fukien provinces on the Asian mainland. From the early 17th century until 1885, T'ai-nan remained not only Formosa's largest town but also its political capital.

The city is the centre of a large rice-, sugar cane-, and peanut-producing area. Its manufactured goods include textile and rubber products, sugar, chemicals, plastics, aluminum products, small machinery, iron and steel products, and electrical appliances. T'ai-nan also is the centre of the salt industry along Formosa's southwestern coast, the headquarters of the Chia-nan irrigation system, and the service base for Civil Air Transport. It contains Chengkung University, one of Formosa's leading engineering schools.

(N. S. G.)

**TAINÉ, HIPPOLYTE ADOLPHE** (1828–1893), French thinker, literary and art critic, and historian. Although he achieved fame over a very wide range of disciplines, Tainé's deepest influence on his contemporaries was as an intellectual leader, as the embodiment of the 19th-century cult of science in its most devoted, high-minded, and often coldly rational form. His work represents, above all, a reaction against excessive emotionalism and spiritualist philosophy, and helped to provide a theoretical basis for the literary movement of Naturalism. The novel in particular, he urged, should be a "collection of experiments," a contribution to the scientific understanding of human nature, revealing the physical and psychological determinants of man's behaviour.

**Life and Works.**—When contrasted to the powerful unity of his work, the details of Tainé's life are fairly banal. The son of a solicitor, he was born at Vouziers (Ardennes) on April 21, 1828, and was educated privately at home until his father's death in 1842, when he went with his mother to live in Paris; there he became an outstanding pupil at the Collège Bourbon, and in 1848 he entered the École Normale. He already held unorthodox views, having lost his Catholic faith, and his adherence to Spinozism led to his failure in 1851 in the *concours d'agrégation* in philosophy. Thereafter he taught for brief periods at Nevers and Poitiers, but in 1852 applied for leave of absence and, having returned to Paris, devoted himself to preparing his two doctoral dissertations: *De personis platoniciis* and *Essai sur les Fables de La Fontaine* (1853; revised and published in 1861 as *La Fontaine et ses Fables*). He gained his doctor's degree in May 1853 and began an essay on Livy, *Essai sur Tite-Live* (1855), which, despite criticisms of its philosophical tendencies, was to win a prize from the Académie Française in 1855. In the same year he published his *Voyage aux eaux des Pyrénées* (entitled in later editions *Voyage aux Pyrénées*), a guidebook for which he had gathered material during a holiday necessitated by ill health in 1854.

Tainé was now following the career of a man of letters, and he contributed frequent literary and historical articles to the *Revue de l'Instruction Publique*, the *Journal des Débats*, and the *Revue des deux Mondes*. These articles formed the basis for three books which greatly increased the reputation he had already won by his essays on La Fontaine and Livy. These were *Les Philosophes français du XIX<sup>e</sup> siècle* (1857), a polemical attack upon the eclectic philosophy of Victor Cousin and his school, dominant at that time in university circles, and also a lucid statement of his own theory of knowledge; a first volume of *Essais de critique et d'histoire* (1858); and his outstanding *Histoire de la littérature anglaise* (4 vol., 1863–64). In 1864 he followed Viollet-le-Duc, the architect, as professor of aesthetics and of the history of art at the École des Beaux-Arts in Paris, where he was to lecture for 20 years. His published courses include *Philosophie de l'art* (1865), *De l'Idéal dans l'art* (1867), and those devoted to the philosophy of art in Italy (1866), the Netherlands (1868), and Greece (1869). The 1860s were very productive and happy years. A second volume of essays, *Nouveaux Essais de critique et d'histoire* (1865), includes his justly admired articles on Balzac, Stendhal, and Racine; and in 1867 appeared perhaps the most personal of his works, *Notes sur Paris: vie et opinions de M. Frédéric-Thomas Graindorge*—to be followed by his well-observed, though partial, *Notes sur l'Angleterre* (1872), the result of two stays in England, in 1858 and 1871. In 1868 he married Mlle Denuelle, the daughter of a well-known architect and artist. In 1870 he published the two volumes of *De l'Intelligence*, a major work in yet another discipline, psychology, which had been one of his basic interests since his youth and underlies much of his writing on literature and art. In it he discusses the methodology of psychology and develops the theory of psychological determinism already stated in his literary works.

France's defeat by Germany in 1870–71 deeply affected Tainé and led to a major reorientation of his work. The shift of his interests to politics is already seen in a brochure, *Du Suffrage universel et de la manière de voter* (1872). Above all he determined to seek the causes of the political instability which he held responsible for France's plight; he devoted the rest of his life to this end and to producing his great historical work, *Les Origines de la France contemporaine*. He even resigned his professorship after 1883 in order to be freer for this task, but he died (in Paris on March 5, 1893) before it was completed.

A first volume of his history, on *L'Ancien Régime*, appeared in 1876, followed by three volumes on the Revolution (1878–84). Only one volume of *Le Régime moderne* was published in his lifetime (1890); a second volume came out in November 1893. The entire work was reissued in 1899 in 11 volumes. There also appeared after his death his *Derniers Essais de critique et d'histoire* (1894), and an unfinished autobiographical and psychological novel, written c. 1861, *Étienne Mayran* (1910).

**Scientific Method and Assessment.**—Of a rationalist cast of mind even as a youth, Tainé lost his Christian faith at the age of 15, and thereafter his ideas were formed in particular by his study of the "Idéologues" (especially Destutt de Tracy [q.v.] and of Spinoza and Hegel. From the former group he took his positivism (q.v.)—his belief that all knowledge of reality must come from sense-experience; his emphasis on the collection of facts; and his rejection of all *a priori* knowledge. From the metaphysicians, on the other hand, he derived his lifelong aspiration to reach a synthetic explanation of the whole of life and the universe. According to Tainé, the scientific method gives certainty, but it lacks completeness, because it is confined to the natural sciences. He argues that it can and should be applied not only in sociology, as his predecessor Auguste Comte (q.v.) had claimed, but also in the study of literature and art, in psychology, and above all in the realms of metaphysics and ethics; he even speaks of basing "a new religion" upon science.

The method Tainé propounded for the study of literature (and also art) is well stated in the introduction to his history of English literature, perhaps his most celebrated piece of writing and a basic text for the understanding of his literary criticism. This introduction also contains his most notorious—and misunderstood—

section that "*le vice et la vertu sont des produits comme le vitriol et le sucre*" ("vice and virtue are products like vitriol and sugar"). For Taine, the examination of literary "documents" leads to a closer understanding of the psychology of their author; this, complemented by scrutiny of the facts of his life and personality, makes it possible to discern the "*faculté maîtresse*"—the predominant characteristic—which determines his work; this, in turn, can then be "explained" by reference to three great conditioning facts, "*la race*," "*le milieu*," and "*le moment*"—that is, roughly, his inherited personality, his social, political, and geographical background, and the historical situation in which he writes. The permanent impulsion of "*la race*" combines with the given environment ("*le milieu*") to produce the "*acquired speed*" ("*vitesse acquise*") at any given moment. It is evident that Taine's interest here is less in literature itself than in historical causation and psychology, and his method encouraged in his admirers an excessive preoccupation with biography and literary history at the expense of critical judgment. However, Taine's own abilities as a critic are revealed in his essays on Balzac and Stendhal (whose masterly psychological insight Taine was one of the first to acknowledge and admire), and in his lectures on painting.

Taine's scientific ambitions are most fully revealed in his psychological and philosophical writings. He stands alongside Théodule Ribot and Pierre Janet (q.v.) as a champion of scientific psychology, and though much of *De l'Intelligence* is outdated, it helped to modify contemporary methods of research by its emphasis on experiment, the search for causes, the physiological basis of personality, and the study of pathological cases. At the same time it intensified opposition to his ideas. He was angrily accused of holding a determinist and materialist view of man—not altogether unfairly, even though he himself claimed to reject materialism and argued that moral responsibility was compatible with determinism as he conceived it. In philosophy Taine seeks nothing less than to fuse positivism with German idealism, and to provide a method for a scientific metaphysics. He maintains that we can climb the pyramid of knowledge by a process of successively repeated abstractions and verifications, moving from the causes of particular phenomena to the causes of these causes, ultimately grasping the final causes of Life itself. And, as Taine contemplates this "hierarchy of necessities," which in his view comprises Nature, he yields to an exalted pantheism, inspired by Spinoza, in which he seeks to find a replacement for the Christian religion. Indeed, his personal philosophy, movingly expressed in essays on Iphigenia (contained in *Derniers Essais*) and Marcus Aurelius (in *Nouveaux Essais*), can be summarized as a fusion of pantheistic belief in the goodness of Nature with a stoic reconciliation to the individual's transitoriness and sufferings. Unfortunately, he fails to demonstrate the moral perfection he attributes to his impersonal "universal God," or to reconcile it with the existence of suffering and evil.

Taine's monumental work as a historian, *Les Origines de la France contemporaine*, is equally animated by scientific aims. Only by understanding the causes of France's situation would it be possible to legislate for its future development. His long analysis seeks to show that France's primary fault lies in excessive centralization, that this originated during the *ancien régime*, and that it was further intensified by the French Revolution, on which he shares and develops Burke's hostile view. Far from promoting liberty, as most Frenchmen believe, the Revolution merely transferred absolute power to even more illiberal hands. Undoubtedly his discussion is biased by the conservative and reactionary thesis he wishes to justify, and both the factual and the interpretative reliability of this work have been severely questioned, notably by Alphonse Aulard (see *Bibliography*). Here, as in much of his writing on literature and art, his primary merit lies less in the scientific objectivity he claimed than in his imaginative reconstruction of the past, and in his bold, stimulating generalizations, many of them not the dispassionate discoveries he believed them to be, but brilliant, intuitive hypotheses.

Émile Zola (q.v.), whose naturalist novels were particularly influenced by Taine's philosophy, once said that in Taine a poet and a rationalist were in conflict; one may sometimes think that

the living interest of his works derives from the former rather than the latter. And although the nature of his literary criticism may seem brutal compared to the nuances of Sainte-Beuve's portraits, there is more subtlety to his determinism than at first appears. More generally, it is hard to deny that Taine promised more for the scientific method than it could achieve, and his overconfident trust in it provoked in the end either disillusionment (shared in part by Taine himself in his old age) or sharp reaction toward orthodox religion. Yet while later critics have justly shown the weaknesses of his thought, he still retains his power to stimulate and his representative stature as an outstanding scientific humanist of his age.

**BIBLIOGRAPHY.**—There is no edition of Taine's collected works, but an authoritative biography and a selection of his correspondence have been edited by his widow under the title *H. Taine: sa vie et sa correspondance* (4 vol., 1902–07; *Life and Letters of H. Taine*, 3 vol., 1902–08). Most of Taine's works have been translated into English. Useful monographs include G. Barzellotti, *La Philosophie de H. Taine*, Fr. translation of Ital. original (1900); V. Giraud, *Essai sur Taine: son oeuvre et son influence* (1901; 6th ed., 1912); A. Aulard, *Taine, historien de la Révolution française* (1907); F. C. Roe, *Taine et l'Angleterre* (1923); D. D. Rosca, *L'influence de Hegel sur Taine théoricien de la connaissance et de l'art* (1928); P. V. Rubow, *Hippolyte Taine: étapes de son oeuvre* (1930); A. Chevillon, *Taine: Formation de sa pensée* (1932); M. Leroy, *Taine* (1933); A. Cresson, *Hippolyte Taine, sa vie, son oeuvre* (1951); S. J. Kahn, *Science and Aesthetic Judgment: a Study of Taine's Critical Method* (1953).

(D. G. CH.)

**T'AI-PEI** (Japanese TAIHOKU), one of the chief cities of Formosa (Taiwan). Founded in 1708, T'ai-pei after the middle of the 19th century became an important centre for overseas trade through its outport, Tan-shui. This trade was based upon tea and was dominated by British trading companies.

Situated in the centre of the largest agricultural basin in northern Formosa, T'ai-pei (population in 1964 was estimated to be 1,117,000) forms the nucleus of a major industrial area. The T'ai-pei industrial complex includes light and heavy industries within the urbanized area and also in several industrial suburbs, including Pan-ch'iao and Nan-chiang. Cotton and artificial fibre textiles, rubber goods, electrical appliances, alcoholic beverages, metal products, chemicals, coke, and printed materials are produced. T'ai-pei also is the island's major communications centre, containing the central workshops of the government-owned railway and Formosa's international airport. National Taiwan University and the Taiwan Provincial Normal University, as well as several professional and specialized training schools, are located in T'ai-pei. Because it contains more mainland Chinese than any other Formosan city, characteristic types of mainland entertainment, such as opera and fine regional restaurants, are found there.

Under Japanese rule (1895–1945) T'ai-pei was the seat of the Taiwan government-general; as a result it acquired the characteristics of an administrative centre, such as public buildings and extensive civil servant housing facilities. After the Communists took China in 1949, it became the capital-in-exile of the Nationalist government of the Republic of China, headed by Chiang Kai-shek.

(N. S. G.)

**T'AI P'ING REBELLION.** The T'ai P'ing rebellion of 1851–1864 in China was a great national religious-political upheaval. It inspired many other rebellions and revolutions in late 19th-century China, culminating in Sun Yat-sen's overthrow of the Manchu dynasty in 1911–12. Historical judgment of it has varied. The rebellion has been condemned as the work of "Cantonese bandits" or "long-haired bandits," and has been praised as a national agrarian and proletarian revolution. This great upheaval grew out of a complex background including political corruption of the Manchu regime, foreign aggression during and after the Opium War of 1839–42, agrarian distress, and severe famines that left many people homeless and ready to join the T'ai P'ings.

The titular leader of the rebellion was Hung Hsiu-ch'üan (1814–64), a Cantonese who had struggled in vain to gain office through government civil service examinations. After taking the metropolitan examination at Canton in 1836 he was given nine Christian

founded by the Rasulids (13th–15th centuries) and rebuilt by the Turks in the 16th–17th centuries. The Rasulids and the Tahirids (1453–1516) also built schools, some of which still exist. Ta'izz is linked by unsurfaced but motorable roads with Aden and Al Hudaydah, and a hard-surfaced road to San'a' was under construction in the 1960s. A water supply to the town was installed by the United States. See also YEMEN. (W. H. Is.)

**TAJ MAHAL**, the mausoleum built on the south bank of the Jumna river, outside Agra in India, on the orders of the Mogul emperor Shah Jahan in memory of his beloved wife, Arjumand Banu Begum, called Mumtaz Mahal, "chosen one of the palace" (of which Taj Mahal is a corruption). She died in childbirth in the town of Burhanpur in 1631 after having been the emperor's inseparable companion since their marriage in 1612. The building was commenced in 1632, after plans had been prepared by a council of architects from India, Persia, central Asia and beyond; the credit for the final plan is given to one Ustad Isa, either Turkish or Persian, although the master builders, masons, inlayers and calligraphists, like the materials they worked with, came from all over India and central Asia. More than 20,000 workmen were employed daily to complete the mausoleum building itself by 1643, although the whole Taj complex took 22 years to complete, at a cost of 400 lakhs of rupees.

The complex consists of a rectangle measuring 634 yd. by 334 yd. aligned north and south. A central square garden area, 334 yd. on each side, leaves an oblong area at each end; that at the south consists of the sandstone entrance gateway with its attendant service buildings, while that at the north (river) end comprises the mausoleum itself, flanked on the west and east walls by two symmetrically identical buildings, the mosque and its jawab ("answer") respectively. All is enclosed within a high red sandstone boundary wall with octagonal pavilion turrets at the corners, while outside the enclosure at the south are ancillary buildings such as stables, outhouses and guard quarters. The whole complex is the begum's memorial; it was conceived and planned as an entity, since Mogul building practice allowed of no subsequent addition or amendment. Its northern end is the most significant architecturally, with mosque and jawab both facing the mausoleum itself. The mosque and jawab of red Sikri sandstone, with marble necked (not bulbous) domes and architraves and some restrained *pietra dura* surface decoration, contrast well with the mausoleum of pure white Makrana marble. This mausoleum, standing on a 312-ft.-square marble plinth 23 ft. high, is a square of 186 ft. with chamfered corners and with a massive arch in each face, rising to 108 ft.; over all is a bulbous double dome, supported on a tall drum, the pinnacle of which stands 243 ft. above garden level. The sky-line rhythm is enhanced by parapets over each arch, corner pinnacles and domed kiosks over each corner. At each corner of the plinth stands a three-storied minaret, 138 ft. high to the crowning kiosk; the countersunk face joints of the marble bricks provide textural contrast with the highly finished marble of the mausoleum, but unfortunately recall factory chimney construction to the sophisticated western beholder. Inside the mausoleum is the octagonal chamber, embellished with low-relief patterns and fine *pietra dura*, containing the cenotaphs of the begum and Shah Jahan. These, of marble decorated with superb *pietra dura*, are enclosed by an exquisite perforated marble screen studded with precious stones. A vault below, at garden level, contains the true sarcophagi.

The minarets lead the observer's eye from the mausoleum to its setting; this is now somewhat unsatisfactory, as trees obscure the view of other structures, and from the garden there is some feeling of restlessness; but from the river or from the fort the balance restores itself, and justifies H. R. Nevill's remark that "the Taj . . . is within more measurable distance of perfection than any other work of man" (*Agra Gazetteer*, 1921). Its design, successor in the indigenous tradition to the mausoleums of Humayun and the Khan-i-khanan at Delhi, has been criticized as "too feminine"—thus complimenting the designers' intentions. The Moguls are said to have "built like Titans and finished like goldsmiths"; certainly the Taj Mahal is their finest jewel. See ISLAMIC ARCHITECTURE.

A. Smith, *History of Fine Art in India and Ceylon*, pp. 182–185 (1930); E. B. Havell, *A Handbook to Agra and the Taj*, appendix i, new ed. (1924).

**TAKIZAWA BAKIN** (1767–1848), Japanese novelist regarded as the preeminent writer of Edo (now Tokyo), who deserves a place among the world's great storytellers, was born in Edo on July 4, 1767, the third son of a low-ranking samurai. Suffering, misery, and death filled his youth. His father and mother died before he matured, and, because of the famine and plague that struck Edo after 1780, Bakin alone lived to continue his family name. After much drifting, he relinquished samurai status, married a merchant's widow (for security, not love), and devoted over 50 years to writing. He died on Dec. 1, 1848.

With his more than 30 long novels—known as *yomihon*, "reading books"—Bakin created the historical romance in Japan. Court romances, military chronicles, *nō* plays, popular dramas, legends and Chinese vernacular fiction all furnished him material. Although he borrowed from many sources, he added much that was original, and few authors have ever matched his tenacity and his devotion to craft. He freed the novel in Edo from subservience to actor, illustrator, and raconteur. Loyalty, filial piety, and restoration of once-great families comprised his main themes. His special attention to Chinese civilization, Buddhist philosophy, and national history was tempered by a concern for language and style, compassion for his fellow man, and a belief in human dignity. Still, the samurai tradition and his own innate stubbornness led him to support the established order and made him less an original thinker than an interpreter of his age. Although he himself irrevocably forsook his samurai status, he tried his utmost to preserve his son's samurai privileges. Among Bakin's *yomihon*, *Chinsetsu yomiharizuki* (1806–11; "Crescent Moon: the Adventures of Tametomo") and *Nansō Satomi hakken-den* (1814–42; "Satomi and the Eight 'Dogs'"), both on the theme of restoring a family's fortunes, are acclaimed as classics of Japanese literature. (L. M. Zo.)

**TAKLA MAKAN**, a desert in central Asia, the major central division of the Tarim basin. In general the Takla Makan is a region of drift sand and moving sand dunes, and is a waterless area except for the Khotan and Keriya rivers, which carry water northward into the desert. The sand dune desert is uninhabitable away from these rivers and from the Tarim river, which skirts the northern margins. The sand dunes occupy chiefly the south and southwest parts of the Takla Makan, where the full force of the northeast winds is felt. In this area there are two systems of dunes; one, of high chains, stretches from east to west and the second, of transverse dunes, runs from north to south or northeast to southwest. The steeper sides of the dunes generally face toward the south, away from the direction of the prevailing winds, though there is local variation in alignment, facing and movement.

Between the lower Tarim river, in the northeast, and the Charchan desert, in the southeast, the surface generally is different from that of the rest of the Takla Makan. In this region the sand dunes are interrupted by tracts of level soil, or by areas of old channels, bare mesas and erosional remnants, swept clean by the wind. This is the zone in which the Tarim river and the lake, Lop Nor, have wandered repeatedly, so that in places there is fresh to brackish water available near the surface.

Vegetation and animal life are almost nonexistent in the heart of the Takla Makan, but along the permanent streams and locally in the eastern sector various steppe plants, reeds, tamarisks and poplars provide a thin scattering of plant life. On the lower Tarim river, and around Lop Nor, heavy reed growth does occur. The animal life of the region is concentrated at localities providing water and vegetation. Hares, rodents, foxes, wolves, wild pigs, a few antelope and, in a few places in the east, wild camels are among the land animals. In general the animal population of the eastern sector is greater than that of the western zone. A variety of fish and birds are found along the lower Tarim river and throughout Lop Nor.

The climate of the Takla Makan is one of extremes. Winter temperatures as low as  $-23^{\circ}$  or  $-24.5^{\circ}$  C ( $-10^{\circ}$  or  $-12^{\circ}$  F) occur almost everywhere, and a temperature of  $-30^{\circ}$  C ( $-22^{\circ}$  F) has been observed in the southeast, where winter snowstorms sometimes occur. Temperatures as high as  $30^{\circ}$  C ( $86^{\circ}$  F) have been recorded in late spring, but it is likely that higher temperatures occur in the interior dune areas in midsummer. Suffocating sandstorms occur, often enveloping the desert for days and producing an impenetrable dust haze.

See also SINKIANG; TARIM; LOP NOR.

(J. E. SR.)

**TALAT PASHA, MEHMED** (1874–1921), a leader of the Young Turk revolution, was born in Edirne, Turkey, in 1874, the son of a minor Turkish official. After attending the Law School in Salonika (Thessaloniki), he returned to Edirne and worked in the local post office but was soon arrested for subversive political activity. Released two years later (1895), he became first a clerk, then chief clerk at the Salonika post office. In 1908 he was again dismissed, as being a member of the Society of Union and Progress, the organ of the Young Turk movement. After the Young Turk revolution in that year he became deputy for Edirne in the Turkish Parliament and was appointed minister of the interior (1909). He then became successively minister of the post office and president of the Society of Union and Progress. When World War I broke out he was again minister of the interior and in this capacity had to take responsibility for the ruthless transportation of the disaffected Armenians from the eastern vilayets to Syria and Mesopotamia, in the course of which the majority died of hunger, disease, and massacre. In 1917 he became grand vizier and held this post until the end of the war. When the armistice was signed in 1918 he escaped to Europe but was killed by an Armenian in Berlin on March 15, 1921. Although not well-educated, Mehmed Talat Pasha was intelligent and honest and was an idealist who loved and served his country well. Until the outbreak of World War I his influence was on the side of the Entente powers rather than on that of Germany.

(M. P. P.)

**TALavera DE LA REINA**, a town of central Spain, in the province of Toledo, 70 mi. (113 km.) SW of Madrid. It lies on the right bank of the Tagus near its confluence with the Alberche. Pop. (1960) 31,900 (municipal). Historic monuments include the town walls, with 18 watchtowers dating from the 12th–13th centuries; the Gothic church of Santa María la Mayor; and the Mudejar church of Santiago. The town is on the Madrid–Cáceres railway. Agriculture is the main occupation, with tobacco and cotton crops forming the basis of much local industry, which also includes the manufacture of olive oil and agricultural machinery, and milk processing.

The town was of Roman origin and was conquered by Alfonso VI in 1083; Alfonso XI gave it to his queen, Maria of Portugal, whence the name “de la Reina.” From the 16th century it was an important centre for woolen manufactures, but was even more noted for its silk and porcelain. In the 18th century the porcelain industry declined although it was revived to some extent after 1905. The royal silk factory, established in 1748, was closed in 1851. Economic recovery in the 20th century was largely due to the irrigation of land on the right bank of the Tagus which facilitated the cultivation of new crops.

In the Battle of Talavera (July 1809) during the Peninsular War (*q.v.*), the English under Sir Arthur Wellesley, in cooperation with Spanish troops, defeated the French, who were commanded by several generals including King Joseph Bonaparte. As a result of this victory Wellesley was made Viscount Wellington.

**TALBOT**, the name of one of the oldest families in the English nobility; it traces its descent from RICHARD TALBOT (d. 1174/75), who held Eccleswall and Linton, in Herefordshire, in the time of Henry II. Records mention several persons called Talbot living earlier in England, and in Normandy before 1066, among them Geoffrey Talbot (d. 1140), an opponent of King Stephen; but since Talbot was at first a nickname and not a hereditary surname, their relationship is obscure.

The descendants of Richard Talbot, with whom the proved pedigree begins, ranked for several generations among the lesser families of the Welsh border counties. GILBERT TALBOT (1276–

1346) took part with other Marcher lords against Edward II's favourites, the Despensers, who had wrested estates from his daughter-in-law Elizabeth Comyn. With his son, Richard, he was taken prisoner by the royal forces at Boroughbridge (1322) but was later pardoned and restored to his estates. He was afterward king's chamberlain and justice of south Wales, and was summoned to parliament as a baron (1332). His son, RICHARD (c. 1305–56), 2nd lord, claimed extensive lands in Scotland in right of his wife, Elizabeth, daughter of John Comyn of Badenoch, and in 1332 he joined Edward Balliol in his invasion of Scotland, being present at the victory of Dupplin (Aug. 12). Captured by the Scots in Sept. 1334, he was released for a ransom of £2,000. His wife, also a coheirress of the Valence earls of Pembroke, brought him the manor of Painswick in Gloucestershire and the castle of Goodrich on the river Wye; their grandson later acquired in her right the Irish lordship of Wexford (1389). Richard afterward fought with the English armies in France at Morlaix (1342) and Crécy (1346). His son, GILBERT (c. 1332–87), served in France and also Spain. The family estates in Herefordshire, Gloucestershire, Oxfordshire and Kent were further increased by the marriage of Gilbert's son, RICHARD (c. 1361–96), to Ankaret, daughter and heiress of John, 4th Lord Strange of Blackmere, who brought him Whitchurch in Shropshire and other lands. His son, GILBERT (c. 1383–1418), 5th lord, campaigned in Wales against Owen Glendower, and, after proving himself one of Henry V's most vigorous captains in France, died during the siege of Rouen. On the death of his infant daughter and heir (1421), he was succeeded as 7th lord by his brother, JOHN (1384–1453), whose marriage to Maud, heiress of the lords Furnival, had brought him wide estates in Yorkshire, including Sheffield castle, which became a favourite family residence until 1618. In reward for his distinguished services in France he was created earl of Shrewsbury (1442) and earl of Waterford (1446).

The 1st earl's son, JOHN (c. 1413–60), was chancellor of Ireland during his father's lifetime and treasurer of England (1456–58). A strong Lancastrian, he was rewarded with grants from the forfeited Yorkist estates (1459–60) and was killed fighting for Henry VI at Northampton (July 1460). JOHN (1448–73), 3rd earl, at first shared his father's loyalties and was present in Henry VI's army at the second battle of St. Albans and at Towton (1461), but afterward made his peace with the new king, Edward IV, and was appointed chief justice of north Wales in 1471. His son, GEORGE (1468–1538), 4th earl, began a family tradition of devoted service to the Tudor kings. He fought at the battle of Stoke (1487), was steward of the household (1506–38), commanded the army which invaded France in 1513, and, as king's lieutenant in the north, crushed the rebels of the Pilgrimage of Grace (1536). FRANCIS TALBOT (1500–60), who succeeded his father as 5th earl, joined in the invasions of Scotland (1542 and 1544) and spent much of his life on the Scottish borders, being president of the council of the north from 1549 until his death. His son, GEORGE (c. 1522–90), 6th earl, who was styled Lord Talbot during his father's lifetime, was selected by Elizabeth I for the unenviable position of custodian of Mary Stuart, who spent the years 1569–84 in his castles at Sheffield and Tutbury or at Chatsworth house. His task was complicated by the limited funds allowed him by Elizabeth, and by the malicious attempts to discredit him of his second wife, Bess of Hardwick.

The 6th earl was succeeded in turn by two of his sons, but in 1618 the direct male line descended from the first earl ceased, and the title and estates passed to the head of a cadet branch of the family founded by SIR GILBERT TALBOT (d. 1517) of Grafton, Worcestershire, a younger son of the 2nd earl. This was GEORGE TALBOT (1566–1630), 9th earl, a Roman Catholic like nearly all his descendants until 1856, who had been ordained priest before he succeeded to the title. His great great nephew, CHARLES (1660–1718), 12th earl, was raised to the dignity of a duke for his services to William III (*see* SHREWSBURY, CHARLES TALBOT, Duke of), but as he left no son this title died with him and the earldom passed to his cousin, GILBERT (1673–1743), a Roman Catholic priest who never assumed the title. From this time the direct line of Sir Gilbert Talbot of Grafton began to fail. A

nephew three times succeeded to an uncle, and the title then passed to a cousin, **BERTRAM ARTHUR TALBOT** (1832–56), the 17th earl, who died unmarried. The lands were claimed under his will by Lord Edmund Howard, a younger son of the 14th duke of Norfolk and afterward Viscount Fitzalan, but the courts decided that the title and estates should remain together, and a successor to the earldom was found in **HENRY JOHN CHETWYND-TALBOT** (1803–68), Earl Talbot, head of another line of the descendants of Sir Gilbert Talbot of Grafton, who became the 18th earl of Shrewsbury. The head of this family a century before had been **WILLIAM TALBOT** (d. 1730), successively bishop of Oxford, Salisbury and Durham. His son, **CHARLES** (1685–1737), lord chancellor (1733–37), was created Baron Talbot of Hensol in 1733. Charles's son, **WILLIAM** (1710–82), was raised to the dignity of Earl Talbot in 1761, and William's nephew **JOHN CHETWYND** (1750–93) added the title of Viscount Ingestre (1784), now usually borne by the earl of Shrewsbury's eldest son. All these titles have since been united in the line descended from the 18th earl. (C. D. R.)

**TALBOT, ARTHUR NEWELL** (1857–1942), U.S. engineer, one of the foremost authorities of his day on reinforced-concrete construction, was born in Cortland, Ill., Oct. 21, 1857. He was graduated from the University of Illinois and later served there as assistant professor of engineering and mathematics (1885–90) and professor of municipal and sanitary engineering, in charge of theoretical and applied mechanics (1890–1926).

Talbot was instrumental in establishing the engineering experiment station in 1904 at the University of Illinois, the first of its kind. His early investigations of concrete and reinforced concrete led to a number of important publications by the station, and he established in the United States the mechanical method of analysis of reinforced-concrete beams.

In 1914 Talbot began extensive studies on stresses in railroad tracks, which led to important findings for improvement of rails and roadbed. He also served as a consultant on problems concerning water purification and municipal sanitary works. Talbot died in Chicago on April 3, 1942. (S. C. Hr.)

**TALBOT, MARY ANNE** (1778–1808), English "Amazon" who served in the English army and navy disguised as a man, was born in London on Feb. 2, 1778. She believed herself to be the illegitimate child of William Talbot, 1st Earl Talbot. Seduced in January 1792 by a Capt. Essex Bowen, she accompanied him to Santo Domingo, in the Caribbean, disguised as his footboy and with the name John Taylor, and then to Flanders as a drummer. She was present at the capture of Valenciennes (July 1793), where Bowen was killed, and then deserted and joined a French lugger. Captured by the British in the English channel, she was transferred to the "Brunswick" and was wounded in Adm. R. Howe's victory of June 1, 1794. Soon at sea again, she was captured by the French and imprisoned for 18 months at Dunkirk. After a voyage to the United States in 1796, she returned to London in November 1796 and was seized by a press-gang, when her real identity was discovered. She later became a servant of Robert Kirby, a London publisher, who published her story in his *Wonderful and Scientific Museum*, vol. ii (1804) and in *The Life and Surprising Adventures of Mary Anne Talbot* (1809). She died in Shropshire on Feb. 4, 1808.

**TALBOT, WILLIAM HENRY FOX** (1800–1877), English photographer, contributed the basic process for photogravure (see GRAVURE: History; PHOTOGRAPHY: History). He was born at Melbury House, near Evershot, Dorset, on Feb. 11, 1800, and died there on Sept. 17, 1877. He was educated at Harrow and at Trinity College, Cambridge; for the 50-year period after he earned his M.A. (1825), he published many articles in physics, chemistry, mathematics, astronomy, and archaeology. Before L. J. M. Daguerre in 1839 exhibited pictures taken in sunlight, Talbot had obtained similar success, and as soon as Daguerre's discoveries became known he communicated the results of his experiments to the Royal Society. In 1841 he made known his invention of the calotype or Talbotype process and, after the development of the collodion process by F. S. Archer (1851), devised a method of instantaneous photography (see CAMERA LUCIDA AND CAMERA OBSCURA). His antiquarian interests led him to become one of

the earliest to decipher the cuneiform inscriptions from Nineveh (q.v.).

His works include *Pencil of Nature* (1844–46), of unusual interest because it was the first known book to be illustrated entirely with photographs; *Hermes, or Classical and Antiquarian Researches* (1838–39); *Illustrations of the Antiquity of the Book of Genesis* (1839); *English Etymologies* (1846).

See G. Grigson and C. H. Gibbs-Smith (eds.), *People . . .* (1954); B. Newhall, *The History of Photography . . .*, rev. and enlarged ed. (1964).

**TALBOT OF HENSOL, CHARLES TALBOT**, 1st BARON (1685–1737), English lawyer, lord chancellor of Great Britain from 1733 to 1737, was the eldest son of William Talbot (later bishop of Durham), a descendant of the 1st earl of Shrewsbury. Educated at Eton and at Oriel College, Oxford, he became a fellow of All Souls College in 1704. He was called to the bar in 1711 and in 1717 was appointed solicitor general to George, prince of Wales (later George II). He was a member of parliament for Tregony, Cornwall (1720–22) and for Durham (1722–33). He became solicitor general in 1726 and lord chancellor in 1733, when he was created Baron Talbot of Hensol. He died at his house in Lincoln's Inn Fields, London, on Feb. 14, 1737. Talbot an efficient and scrupulous chancellor, enjoyed the reputation of a wit; he was a patron of the poet James Thomson, and Joseph Butler (later bishop of Durham) dedicated his *Analogy* (1736) to him.

See J. Campbell, *Lives of the Lord Chancellors*, vol. iv (1846).

**TALC** is the mineral name for the familiar hydrous magnesium silicate, a common mineral occurring as veins, foliated masses and as a constituent in certain rocks in metamorphic terranes. Talc is distinguished from almost all other minerals by its extreme softness. The hardness of 1 (easily scratched with the fingernail) imparts a soapy or greasy feel which accounts for the name soapstone or steatite for the compact aggregates of talc. Soapstones have been employed since ancient times for carvings, ornaments and utensils. Assyrian cylinder seals, Egyptian scarabs and Chinese figure carvings are notable examples. The resistance to attack from most reagents and to moderate heat makes soapstones especially suitable for sinks and countertops. Talc is also used for lubricants, leather dressings, toilet and dusting powders and certain marking pencils. The major industrial uses of talc and soapstone are in ceramics, paint, rubber, insecticides, roofing and paper.

The colour of talc is white, gray, yellow or various shades of green with a pearly or silvery lustre. Talc is usually found in foliated masses of thin, small, sometimes hexagonal plates. The individual plates easily separate along the perfect basal cleavages into thin flexible but inelastic lamellae (cleavage fragments of muscovite (q.v.) which can be confused with talc are elastic). Pyrophyllite (q.v.) can be distinguished from talc only by optical or chemical methods.

**Mode of Occurrence and Composition.**—Talc is found as a metamorphic mineral in the lower facies of metamorphism and is often associated with other minerals such as serpentine, tremolite (amphibole) (qq.v.) and forsterite (olivine; q.v.) and almost always associated with carbonate: calcite, dolomite or magnesite (qq.v.). Talc,  $Mg_3Si_4O_{10}(OH)_2$ , can occur as an alteration of a pre-existing mineral such as tremolite or forsterite as evidenced by preserving the crystal outlines of the pre-existing minerals. Talc also occurs as veins and masses formed at the expense of and replacing pre-existing mineral aggregates. Soapstones have two general types of occurrences: (1) a large group of soapstones are found intimately associated with metamorphosed carbonate rocks probably originally rich in magnesium. By the addition of water and silica and the removal of carbon dioxide, talc can be formed.

(2) a large group of soapstones are found intimately associated with olivine- and/or pyroxene-rich igneous rocks which have been extensively altered by the addition of water and carbon dioxide or water and silica to form talc, for example:

or the reaction may be as follows:

A sequence of mineral formation ending in talc is very commonly observed: olivine plus pyroxene is altered to tremolite, which is altered to serpentine, which in turn is altered to talc plus carbonate. The alteration of serpentine by the addition of silica to form talc is common, with the result that serpentine-rich rocks and soapstones are usually found together. The conditions for the formation of talc apparently are often met in metamorphism—as evidenced by the world-wide occurrence of soapstones in many metamorphic terranes.

One of the remarkable features about talc is its simple, almost constant composition. Unlike other silicates, even closely related ones, talc appears to be unable to accept iron or aluminum into its structure and form solid solution series (see *MINERALOGY: The Nature of Minerals: Solid Solution*). This is especially curious because an iron analogue of talc is known, and the structurally related chlorite (*q.v.*) forms at least a partial solid solution series between the iron and magnesium end members.

**Crystal Structure.**—The crystal structure of talc, a phyllosilicate, accounts for its physical properties. The phyllosilicates are characterized by a hexagonal sheet structure arrangement of the  $\text{SiO}_4$  tetrahedral groups formed by the sharing of three oxygen atoms from each  $\text{SiO}_4$  tetrahedron with neighbouring  $\text{SiO}_4$  tetrahedra with the silicon atoms arranged at the corners of hexagons. The fourth (unshared) oxygen atom of the tetrahedron is capable of forming chemical bonds with other metal atoms. (For description of this structure see *AMPHIBOLE; PYROXENE*.) In most phyllosilicates, talc included, the unshared oxygens are on the same side of the sheet. Two such sheets (oriented such that their unshared oxygens face each other) are bonded together by the magnesium atoms with the remaining charges balanced by OH groups (located at the centres of the hexagonal groups) also bonded to the magnesium atoms. This arrangement results in a double-sheet structure which completely satisfies the valence demands of the atoms. Therefore, these double-sheet units cannot be bonded to adjacent units by other metal atoms satisfying remaining charges. Consequently, the talc crystal is made up of stacks of these double-sheet units held together in the stack by the weakest of chemical bonds—the van der Waals' forces. Thus, this stacking can be disturbed by slight forces causing the slipping of the double-sheet units along this perfect cleavage direction.

(G. W. DE V.)

**TALCA**, a province of central Chile, spans coastal mountains, central valley, and the Andean cordillera. Separated in 1833 from Colchagua Province and then enlarged (1927–36) by the annexation of Curicó Province, Talca has an area of 3,915 sq.mi. (10,141 sq.km.). Pop. (1960) 206,154. Molina and Curepto are secondary administrative and trading centres. Grapes, wheat, edible legumes, and alfalfa are the major irrigated crops of the predominantly agricultural province. Sheep, particularly numerous in the coastal mountains, and cattle are the main livestock interests. Talca is served by the national north-south railway and paved highway, and by the railways to Constitución and Perquín. Tourist attractions include the Mondaca hot springs and sports fishing in Laguna del Maule and the Maule and Claro rivers.

**TALCA CITY** in the central valley, is the provincial capital. Founded in 1692, it is one of Chile's larger urban centres, with a population in 1960 of 68,148. Its wide streets and attractive central plaza give Talca a prosperous appearance. The city is a commercial and rail transportation centre. Its industrial products include matches, biscuits, candy, flour, tobacco, and clothing.

(J. T.)

**TALLADEGA**, a city of Alabama, U.S., the seat of Talladega County, is 57 mi. E of Birmingham in the foothills of the Blue Ridge Mountains. The city is in an agricultural and dairying region, with marble and limestone quarries and iron mines. The chief industrial products are cotton textiles, cottonseed oil, ma-

chine parts, pipe fittings, soil pipe, lumber, woolen worsted fabric, and yarn. Talladega College, a coeducational institution founded in 1867 by the American Missionary Association, and the Alabama School for the Deaf and Blind are located there. Nearby are Cheaha State Park and Talladega National Forest. The name Talladega, also applying to mountains south and east of the town, is Indian for "border town" as its site was on the edge of the Creek Indians' land. Andrew Jackson defeated a large force of Indians there in 1813. Talladega was settled in the 1830s and incorporated in 1835; the county was established in 1832. For comparative population figures see table in *ALABAMA: Population*.

(B. CR.)

**TALLAGE**, a term employed, while it was in ordinary usage, in the general sense of "tax," and applied to various seignorial, royal and municipal taxes (most of them also known by other names such as "aid"), but particularly to a tax imposed by the lord of an estate upon his unfree tenants. Tallage of this kind was already an established seignorial perquisite in England, as elsewhere in western Europe, in the 12th century. Its arbitrariness was generally greater than that of similar aids taken by lords from free tenants. Its frequency or its amount or both might be at the lord's will, though on many estates in the 13th century it had already become a fixed charge. In England from the reign of Henry II a lord sometimes required specific royal authority to take a tallage—when, for instance, the estate to be tallaged was a former royal estate.

In England at the end of the 12th century, "tallage" established itself as the name of a royal tax (developed by Henry II but not in principle novel) levied on estates in the king's hand and on boroughs. It was assessed by the king's itinerant justices, who had administrative as well as judicial duties, or by special commissioners. The assessors usually negotiated with the community of a borough or estate for a lump sum, but sometimes took the less popular course of tallaging individuals separately. Royal tallages were most frequent during John's reign; objection to them found expression in the Magna Carta. Under Henry III an interval of two to four years was usual and the average yield seemed no greater than before. At its highest, the yield of a tallage exceeded £5,000, and payment was prompt. London's contribution was by far the largest single item, sometimes exceeding a third of the whole. In the reign of Edward I, as the summons of representatives of boroughs to parliaments became more frequent, parliamentary taxation of boroughs and the king's estates was preferred to tallage. Edward I took a tallage in 1304 after a lapse of 36 years. It was last taken in 1312. An attempt to revive it in 1332 was abandoned in favour of a parliamentary grant.

(ER. S.)

**TALLAHASSEE**, a city of Florida, U.S., the capital of the state and the seat of Leon county, is in the northern part of the state 166 mi. W. of Jacksonville, 200 mi. E. of Pensacola and 20 mi. N. of the Gulf of Mexico. The city and the surrounding region are characterized by rolling hills, lakes, streams and giant magnolia and oak trees. Leon county and the 12 counties immediately to the west and east comprise the "big bend" of north central Florida, an agricultural area producing livestock, "shade-cured" (formerly called Spanish or Florida) tobacco, pecans, tung oil trees and diversified farm products. Among the industries of the city are lumber-planing mills, naval store refineries and pecan processing plants. It is a key wholesaling and distribution point for northwest Florida and southwest Georgia and is the seat of two coeducational universities, Florida State university and the Florida Agricultural and Mechanical university (see *FLORIDA: Education*). Among its stately homes are the Grove (completed in 1830), the Columns (1835), Goodwood (1843) and the governor's mansion (1957).

In 1539–40, Hernando De Soto and a Spanish expedition spent the winter in the vicinity, this incident leading to a local assumption that the first observance of Christmas in the present United States was conducted in or nearby the site at that time. Other Spaniards, while fighting the Apalachee Indians of the region, are supposed to have fortified a hill near the site in 1638. By 1675 seven Franciscan missions were established in the region, San Luis de Talimali, in the western section of the present city,

being the most important. This mission, sometimes called Fort San Luis, was destroyed and the Apalachee Indians were dispersed by Gov. James Moore of South Carolina during Queen Anne's War (the War of the Spanish Succession, 1701–13), when he invaded Florida to punish the Spanish for having incited Indian attacks against white settlers in South Carolina. Tallahassee then acquired its name from a Creek Indian word meaning "abandoned village." From this time until Spain ceded Florida to the United States in 1821, Tallahassee remained quite insignificant.

When Florida became a U.S. territory it had two capitals, one in St. Augustine and one in Pensacola. The first territorial legislature met in Pensacola in 1822, the second in St. Augustine the next year. Tallahassee was named permanent capital in 1823 and the legislature first met there in 1824. Incorporated in 1825, it became the state capital when Florida entered the union in 1845.

Before the American Civil War Tallahassee became a trade centre for the rich cotton plantation country of middle Florida, partially because of its connection with the little port of St. Marks nearby. Negro slavery was more prevalent in Leon and adjoining counties than elsewhere in the state. During the war it was far removed from the significant battle areas. In the late 1800s and early 1900s, when south Florida entered its boom era, Tallahassee declined as a commercial and business centre. After 1940 it regained importance because of its position as the governmental centre of the state. The city has a council-manager form of government, in effect since 1920. The population (1960) was 48,174; standard metropolitan statistical area (Leon county), 74,225. For comparative population figures see table in FLORIDA: Population.

(W. T. Jo.)

**TALLAPOOSA**, a river of northwestern Georgia and east central Alabama, U.S., rises in the piedmont area of western Georgia about 30 mi. WNW of Atlanta and flows southwest in an irregular, steplike course for about 268 mi., joining the larger Coosa River about 10 mi. N of Montgomery, Ala., to form the Alabama River. Its only large tributary is the Little Tallapoosa which joins it about midway in its course. All but the lower part of the drainage basin of about 4,500 sq.mi. lies in the Alabama-Georgia piedmont. Falls at Tallassee, Ala., chief city on the Tallapoosa, about 43 mi. upstream from its mouth, and a steep gradient above that prevented use of the river for navigation. Three private power dams (Martin, Yates, and Thurlow) above Tallassee created reservoirs such as Lake Martin (1,630,000 ac.ft.) for river control and recreation as well as power.

The name Tallapoosa is of Creek origin and many Indian villages were situated along the lower river before the 19th century. The Creek War Battle of Horseshoe Bend (1814) was fought in a river bend near what is now the northern end of Lake Martin, about 9 mi. N of Dadeville, Ala.

**TALLCHIEF, MARIA** (1925– ), U.S. ballet dancer noted for the crisp perfection of her technique, was born in Fairfax, Okla., Jan. 24, 1925, of American Indian descent. After studying with Bronislava Nijinska she joined the Ballet Russe de Monte Carlo in 1942 and soon became a leading dancer. In 1947 she was guest artist at the Paris Opéra, and in 1948, the year it was founded, she joined the New York City Ballet and was for a time its prima ballerina. She joined the American Ballet Theatre in 1960. Tallchief particularly excelled in the roles created for her by George Balanchine in *The Firebird*, *Orpheus*, and *The Nutcracker*.

(Ln. Me.)

**TALLEMANT DES RÉAUX, GÉDÉON** (1619–1692), French writer of informative and entertaining *Historiettes*, or short biographies. Born at La Rochelle on Oct. 2, 1619, of a rich Protestant family, Tallemant went early to Paris and began to frequent literary circles. In 1646 he married Elisabeth Rambouillet in the Protestant temple at Charenton. His later life was made miserable by family bankruptcy and by separation from his wife. She was received into the Catholic Church in 1665, he not until July 1685, about three months before the revocation of the Edict of Nantes. Tallemant died in Paris on Nov. 10, 1692.

Tallemant published nothing in his lifetime save a few poems in anthologies. His *Historiettes* were not published till 1834, from a folio manuscript that had appeared in a Paris auction. This

contains a mass of particulars about leading men and women in Parisian society and French public life of the first half of the 17th century. Tallemant appears to have started writing in 1657 from data collected earlier. A good listener, he also took the trouble to seek out well-informed authorities for his lives (such as Boisrobert on Richelieu and Racan on Malherbe), with the aim of recording anything of interest that was not in the printed histories. His new, disturbing, and apparently chatty information about dignified persons was at first decried, but research has done much to establish its reliability. These acute jottings, often so near to the actual event, may be considered a firsthand source and have been useful as a corrective to later interpretations. There are modern editions by G. Mongrédien, 8 vol. (1932) and in the "Pléiade Series" by A. Adam (1960– ).

See E. Magne, *La Joyeuse Jeunesse* . . . (1921) and *La Fin trouble de Tallemant des Réaux* (1922); also E. Gosse, *Tallemant des Réaux or the Art of Miniature Biography* (1925).

(W. G. Me.)

**TALLENSI**, a Negro tribe of about 40,000 sedentary cultivators densely settled in the open savanna zone of northern Ghana who speak a dialect (Talni) of the Gur language family allied to that of the Dagomba (q.v.). They are barely self-sufficient, growing millet and sorghum as staples, eked out with minor crops, small-scale husbandry of cattle, sheep, goats, and some poultry.

The normal domestic unit is the polygamous joint family of a man and his sons (and sometimes grandsons) with their wives and unmarried daughters. Married daughters live with their husbands in other communities, commonly nearby. Homesteads are scattered and settlements, which merge into one another, are the territory of exogamous, totemic, patrilineal clans or maximal lineages, segmented into a hierarchy of lesser lineages and held together primarily by the sanctions of common ancestor worship. Clans are politically autonomous, and jural authority is vested in clan elders. In one group of clans (Namoos, who claim to be of remote immigrant origin from the Mamprussi people) the senior elder is the chief; in the other group (Talis, who claim to be the aboriginal inhabitants) he is the ritual custodian of the earth; the two groups have affinal and cognatic ties.

Tenacious family and kinship bonds are buttressed by an elaborate ancestor cult that is expressed in a cycle of great festivals at sowing and harvest time in which the chiefs and earth custodians participate. Tallensi have shown considerable adaptability to change, accepting a federal native authority since 1937 and making good use of new schools, markets, and opportunities for labour migration. Under the republic the authority of chiefs and elders was replaced by official administrative agencies. Traditional values remained largely intact, but the expanding economy, education, and increasing Christian influence foreshadowed radical social change.

**TALLEYRAND** (TALLEYRAND-PÉRIGORD), **CHARLES MAURICE DE**, PRINCE ET DUC DE BÉNÉVENT (1754–1838), French statesman and diplomat notable for his capacity for political survival, held high office during the French Revolution, under Napoleon, at the Restoration, and under Louis Philippe. As Louis XVIII's delegate to the Congress of Vienna, his skill in dividing the four allies who had defeated Napoleon won for France an effective voice in the settlement of Europe.

Talleyrand was born in Paris on Feb. 2, 1754, the son of Charles Daniel, comte de Talleyrand-Périgord, then colonel of the French grenadiers, and of Alexandrine de Damas d'Antigny. Both his parents came of old and aristocratic, but not wealthy, families. Charles Maurice was boarded out with a nurse in a Paris suburb, and when he was four years old he fell from a chest of drawers dislocating his foot. This accident lamed him for life. His elder brother having died at the age of five, tradition would have decreed for Charles Maurice a military career; but because of his lameness his parents destined him for the church. From the age of 8 he was a pupil in the Collège d'Harcourt at Paris and at 15

was sent as assistant to his uncle Alexandre, coadjutor to the archbishop of Reims, in the hope that some acquaintance with the activities and splendours of an episcopal palace might arouse in him an interest in his future career. In 1770 he entered the seminary of Saint-Sulpice at Paris; there he spent most of his time reading avidly, usually works such as those of Voltaire or Montesquieu which criticized existing institutions. A rebel by nature, and with no vocation to the priesthood, his behaviour was anything but edifying; and even while he was at the seminary he had a mistress, a young actress who lived nearby. Probably expelled (1775) for his scandalous conduct,

THE GRANGER COLLECTION  
TALLEYRAND, PORTRAIT BY PIERRE PRUD'HON

Talleyrand nevertheless received minor orders at Paris on April 1, 1775; six months later he received from the king the Abbey of Saint-Denis at Reims. After two years' study at the Sorbonne, he took his degree in theology (March 2, 1778), and was ordained on Dec. 18, 1779. The following day his uncle Alexandre, now himself archbishop of Reims, named him his vicar-general.

Talleyrand did not allow his priesthood to debar him from any sort of worldly pleasure. He was a constant companion of the most fashionable wits and beauties of the day, men such as Louis, comte de Narbonne, Armand Louis de Gontaut, duc de Lauzun (later duc de Biron), Emmanuel Henri de Launay, comte d'Antraigues, and the Swiss banker Panchaud; and women like Louise de Rohan, daughter of prince Charles de Rohan-Montauban, comtesse de Brionne, and her daughter-in-law the princesse de Vaudémont, the comtesse de Brienne, and Adelaide Filleul, comtesse de Flahaut. By Adelaide he had a son, Auguste Charles de Flahaut, who became a general under Napoleon and an ambassador under Louis Philippe. In this society Talleyrand discussed secular rather than ecclesiastical affairs, particularly the current developments in revolutionary thought. Nevertheless, in 1780 he was appointed agent general of the clergy, a position which brought him into contact with the ministers of the crown and gave him an apprenticeship in state affairs. In this capacity he made proposals to improve the standard of living of the lower clergy. On Nov. 2, 1788, he was appointed bishop of Autun, and took possession of his diocese on March 15, 1789.

**The Revolution.**—No sooner had he arrived in his diocese than Talleyrand had to deal with elections for the forthcoming meeting of the States General. For his clergy he drew up a program of desired reforms, which they adopted, and for the country as a whole he demanded a constitution that would provide a genuine representative system, guarantees of liberty and property, and the ending of fiscal privilege. His clergy elected him as their deputy to the States General, which met at Versailles on May 5, 1789. During the earlier deliberations, Talleyrand showed himself in favour of the union of the three orders for voting purposes (see FRANCE: History); but he deplored mob rule and hoped that the reforms he had suggested would be carried through by the king, and not imposed upon him. There are doubts, however, of the truth of the story that on the night of July 16-17, 1789, Talleyrand, through the king's brother, the comte d'Artois, urged Louis XVI to use force against the Revolution, saying, when the king refused to do so: "then it only remains for each one of us to look out for himself."

Talleyrand's most important contribution to the work of the Constituent Assembly was his proposal (introduced Oct. 10, 1789, and carried Nov. 2) that church property should be appropriated by the state. He also took part in the debates on the constitution, and spoke (Aug. 4) in favour of the abolition of feudalism. He sponsored a draft law for introducing a uniform system of measures, and also laid before the assembly an important report on education. He notably associated himself with the Revolution

when, as a bishop, he said Mass at an altar erected in the middle of the Champ-de-Mars, on the Fête de la Fédération (July 14, 1790). This proved, in fact, the last Mass he said publicly; that same evening he was in a gaming house and won large sums of money. Increasingly repudiating his identification with the church, he helped bring about passage of the Civil Constitution of the Clergy (July 1790), and was one of the first to take the prescribed oath (January 1791). A few days later, having been elected administrator of the *département* of Paris, he resigned as bishop of Autun. The fact that he no longer held a see did not, however, prevent him from joining two other "constitutional" bishops in the consecration (Feb. 24) of two new bishops who had been elected in accordance with the Civil Constitution. As a result, he was excommunicated by Pope Pius VI (April 13).

The death of Mirabeau (April 2, 1791) seems to have been a turning point in Talleyrand's career. Originally on bad terms, the two men had become more friendly since May 1789, and they frequented the same clubs and gambling houses. Talleyrand was never likely to exercise anything like Mirabeau's influence; but after Mirabeau's death he aspired to take his place as secret counselor of the king and he also replaced Mirabeau on the Directory (the controlling group) of the *département* of Paris. He was trying hard to establish himself among the political élite.

After the Constituent Assembly was dissolved (Sept. 30, 1791), Talleyrand began his diplomatic career. Sent to London by Valdec Delessart, the foreign minister, he had to persuade the English government not to join Austria, Russia, and Prussia, who were proposing to make war on France in order to restore the *ancien régime* there and to prevent the spread of revolution throughout Europe. Arriving in London (Jan. 24, 1792), Talleyrand was coldly received by the royal family, and wrote home that any hopes of an understanding with England were illusory. In meetings with William Pitt, the prime minister, and Lord Grenville, the foreign secretary, he proposed that both countries should guarantee to help defend the other's territories, France specifically recognizing British sovereignty in India and Ireland. Although the British government made no response, Talleyrand became convinced that Great Britain would not join France's enemies, provided that France did not attack the Dutch United Provinces. Returning to Paris (March 10), Talleyrand persuaded the new foreign minister, Charles Dumouriez, to appoint the young marquis de Chauvelin as plenipotentiary in London, and returned there (April 29) as Chauvelin's assistant. France had now declared war on Austria (which was allied to Prussia); Talleyrand managed to extract from the British government a declaration of neutrality (May 25), but events in France, especially the riots of June 20, when the crowds burst into the Tuileries Palace, made his position increasingly difficult and he left London on July 5. Although the fall of the monarchy (Aug. 10; see FRANCE: History) and the September massacres further alienated English sympathies, Talleyrand still sought to postpone Britain's entry into the war. He drew up for the provisional executive council a document designed for circulation to all European governments, which threw on Louis XVI all responsibility for the events of Aug. 10. Forbidden to continue his official mission in London, he was granted a passport to go there privately. Arriving on Sept. 18, he did all he could to avert war with Britain, but the invasion of Belgium by French troops and the opening of the Scheldt River to all shipping (November 1792), followed by the execution of the king (January 1793), made it inevitable. Talleyrand, who had been denounced (Dec. 5, 1792) by the Convention (evidence of his secret communication with the king having been found in the "iron box" in the Tuileries), and who was expelled from England early in 1794, tried unsuccessfully to reach Switzerland or Tuscany and eventually took ship for the United States (March 1794). He remained there for just over two years, profitably engaging in a variety of financial speculations.

**The Directory.**—After Robespierre's fall (July 27, 1794), events in France facilitated Talleyrand's return. On June 16, 1795, he petitioned the Convention to remove his name from the list of *émigrés*, as he had had full permission to leave France. His request was granted on Sept. 4, but he did not sail from Philadel-

phia until June 13, 1796; on July 31 he reached Hamburg, where he spent a month in the company of his friends Karl Friedrich, graf von Reinhard, and the comtesse de Genlis. Reaching Paris on Sept. 20, 1796, he immediately occupied at the Institut National (a reconstruction of Richelieu's Académie Française and other academies) the seat to which he had been elected the previous December. The paper which he read there (July 13, 1797) on the advantages France might derive from new colonies, showed that he again hoped to enter the political arena. Although all the members of the Directory, except Paul Barras, thought him despicable and dangerous, the reorganization of the ministry carried out in July 1797 enabled Barras, at the instance of Mme Germaine Necker de Staël-Holstein, to propose Talleyrand as foreign minister; and J. F. Reubell and L. M. de la Revellière-Lépeaux accepted him on condition that their nominees received other posts (July 18). Talleyrand's position was soon strengthened by the *coup d'état* of Sept. 4, 1797, which removed the two directors (L. N. M. Carnot and Charles Le Tourneur) who had voted against him. Talleyrand approved Bonaparte's conclusion of the Treaty of Campo Formio (Oct. 17-18, 1797) with Austria, thus winning the goodwill of the famous general. Like all the ministers under the Directory, Talleyrand had only limited power, effective control of foreign policy being exercised by Reubell. Talleyrand alone, however, was responsible for a breach between France and the United States, following the indignant withdrawal of the three American envoys from whom Talleyrand had demanded enormous bribes. He joined Bonaparte in urging on the Directory the Egyptian expedition. A year later (June 20, 1799) he tendered his resignation, probably believing that the unstable régime would not survive much longer. Meanwhile, by various means, chiefly the acceptance of large bribes, he had amassed a respectable fortune, and had deposited more than 3,000,000 francs abroad, in London and Hamburg.

Not long after Talleyrand's resignation, Napoleon returned from Egypt, carried through his *coup d'état* of Nov. 9-10, 1799, and established the Consulate. Talleyrand supported him, acting as intermediary to obtain the resignation of Barras, the last of the Directorate, and on Nov. 22 was reappointed foreign minister, an office he was now to hold until 1807.

**The Consulate and the Empire.**—Talleyrand's chief aim was the pacification of Europe, and he immediately began negotiations for peace with England. But they failed, and the first peace treaty (Lunéville, Feb. 9, 1801) was made with Austria. At home, Talleyrand used his influence to facilitate the return of *émigrés* and priests who had refused the oath, and urged the signing of the Concordat (July 1801) between Napoleon and Pope Pius VII. Later (March 10, 1802), at Napoleon's request, the pope signed a brief reconciling Talleyrand with the church and granting him lay status. Then, under pressure from Napoleon, Talleyrand regularized his position by marrying his current mistress, Mme Catherine Grand, the French divorced wife of an English employee of the Indian civil service.

Talleyrand took no direct part in the peace talks with England held at Amiens (1801-02), but he helped the First Consul establish French supremacy in Italy, Germany, and Switzerland. At the *consulta* of leading members of the Cisalpine (now to be called the Italian) Republic, convoked by Napoleon at Lyons (early 1802), Talleyrand engineered various changes in the republic's constitution and the election of Napoleon as its president. In Germany (much to his own profit) he helped to arrange the allocation of certain secularized church lands as compensation to those princes who had lost to France territory on the left bank of the Rhine.

Talleyrand tried hard to avert the renewal of war with England (May 1803) and, although he had helped Napoleon establish himself as "Consul for Life," he hoped to keep Napoleon's ambitions within bounds. His motives in counseling the abduction and execution of Louis Antoine Henri de Bourbon-Condé, duc d'Enghien, are, however, by no means clear. Whether he genuinely believed d'Enghien to be the leader of a plot to overthrow Napoleon, or merely invented the charge to suit his own plans, he was certainly responsible for telling Napoleon that d'Enghien was at Ettenheim

in Baden, just across the Rhine. He urged d'Enghien's arrest on foreign soil, and then did his best, through diplomatic channels, to persuade the rest of Europe to condone the illegal seizure. He did nothing to prevent d'Enghien's execution, but later attempted to recover and destroy those documents in foreign archives which implicated him in the crime. When Napoleon became emperor (May 1804), he rewarded Talleyrand by appointing him Grand Chamberlain of the Empire, with an annual income of 500,000 francs. Later Talleyrand was also appointed to the sinecure office of vice-electoral and was created (June 5, 1806) prince et duc de Bénévent (Benevento, a city in southern Italy formerly in the pope's possession). From his now vast incomes and the enormous bribes he received, he bought the magnificent château de Valençay, in Touraine.

Nevertheless, from 1805 onward, his influence with the emperor began to wane. He failed to persuade Napoleon, after the victory of Austerlitz to conciliate Austria, or to preserve the Holy Roman Empire, which was replaced (1806) by the Confederation of the Rhine and the Empire of Austria. Talleyrand was not given a free hand in the peace talks he conducted with England; they failed, as did negotiations with Russia, the latter because the tsar repudiated a treaty signed in Paris by his envoy Baron d'Oubril and Talleyrand. When France's war with Russia and Prussia was finally ended, by the Treaties of Tilsit (July 7 and 9, 1807), Talleyrand had no part in the negotiations. Alarmed by Napoleon's insatiable ambition, which he saw clearly could lead only to disaster, he resigned his office in August 1807. Napoleon, however, was already disillusioned with his minister. He had received innumerable complaints of Talleyrand's venality, and perhaps already doubted his loyalty. But he continued to consult him, and it seems clear (despite Talleyrand's later denials) that Talleyrand supported Napoleon's invasion of Spain. The deposed Ferdinand VII, with his brother and uncle (see SPAIN: History), were detained in Talleyrand's château de Valençay until 1814. In September 1808 Napoleon took Talleyrand to a gathering of European sovereigns at Erfurt. There Talleyrand had secret talks with Tsar Alexander I, urged him to oppose Napoleon, and thenceforward conducted a secret correspondence with both Russia and Austria. This treasonable activity did not, in fact, involve Talleyrand in any great risk, since it was approved by Joseph Fouché, minister of police, who shared Talleyrand's dismay at Napoleon's policies.

After the divorce of the empress Joséphine (1810), Talleyrand persuaded Napoleon to marry Marie Louise, daughter of the Austrian emperor Francis I, in the hope that alliance with the Habsburgs would provide a sense of achievement and thus modify Napoleon's ambition. But nothing, apparently, could accomplish that, and Talleyrand, hearing (1812) of Napoleon's proposed Russian campaign, declared that this was the beginning of the end. In January 1814 Napoleon asked Talleyrand to return to the foreign ministry in order to negotiate with the allies. Talleyrand, who was already planning to restore the Bourbons, refused, remaining unmoved despite violent abuse from Napoleon. When the allies entered Paris (March 31, 1814), the tsar stayed at Talleyrand's town house and was eventually convinced by him that only a Bourbon restoration would assure peace to Europe. Talleyrand persuaded the senate (only 63 out of 140 members of which were present) to constitute a provisional government of five members, one of whom was to be himself, and to declare Napoleon deposed. The new government immediately summoned Louis XVIII who, on May 13, 1814, appointed Talleyrand his foreign minister.

**The Restoration.**—As France's representative at the Congress of Vienna (1814-15), Talleyrand exhibited his diplomatic skill to the full. By stressing that European reorganization should be based on the principle of legitimacy, he contrived in effect to destroy the Treaty of Chaumont which had been made (March 9, 1814) between the four allies; drawing Austria and England into secret agreements designed to prevent Russia from annexing all Poland and Prussia all Saxony. This new triple alliance succeeded in reducing the territorial claims of the other great powers, and led to the agreement by which France was to retain its 1792 frontiers (after the Hundred Days, however, they were reduced to those of 1790). Nevertheless, the final settlement, by giving Prussia

control of the east bank of the Rhine, ultimately constituted a serious danger for France.

Talleyrand remained at Vienna during the Hundred Days. On Louis XVIII's return to Paris (July 9, 1815), he was appointed president of the council (retaining the office of foreign minister). But the powerful Ultras (extreme royalists) were bitterly opposed to a ministry dominated by two former revolutionaries (Talleyrand and Fouché), and Talleyrand had forfeited the tsar's goodwill by his tactics at Vienna; under pressure, Louis XVIII was obliged to dismiss him (Sept. 24, 1815). Talleyrand then lived in retirement, writing his memoirs, until in 1829 his unerring political sense led him to ally with the Liberals in order to remove Charles X. He established contact with Louis Philippe, duc d'Orléans, and at the Revolution of July 1830 helped to make him king. As Louis Philippe's ambassador in London (September 1830–November 1834) he played a vital part in the negotiations between France and Britain which resulted in the creation of the kingdom of Belgium. The signature of an alliance between France, Great Britain, Spain, and Portugal (April 1834) crowned his diplomatic career.

Talleyrand died in Paris on May 17, 1838. He received the last sacraments, having signed, a few hours before his death, a document in which he declared himself reconciled with the church, and expressed regret for his former irregular conduct. He was buried at Valençay. He had separated from his wife in 1815, and left no legitimate issue.

Totally disregarding his vices, his treachery, and his venality, bourgeois liberals of the 19th century persisted in acclaiming Talleyrand as the great statesman who restored peace and order to Europe at the Congress of Vienna. But the verdict of modern historians, more remote from the conflicts of his period and the results of his work, must be more carefully weighed. His total lack of principle and overweening egoism leave a sense of distaste which neither his undoubted ability, nor his intelligence, nor the superb diplomatic skills, which he used almost always in the service of peace and liberalism, can totally dispel.

**BIBLIOGRAPHY.**—Talleyrand's *Mémoires* were ed. by the duc de Broglie, 5 vol. (1891–92), Eng. trans. by A. Hall, 5 vol. (1891–92). Of his letters and dispatches, the following are the chief collections: G. Pallain, *La mission de Talleyrand à Londres en 1792* (1889); *Le ministère de Talleyrand sous le Directoire* (1891); *Correspondance inédite du prince de Talleyrand et du roi Louis XVIII pendant le congrès de Vienne* (1881); *Ambassade de Talleyrand à Londres, 1830–1834*, 2 vol. (1891); P. Bertrand, *Lettres inédites de Talleyrand à Napoléon, 1800–1809* (1889); M. Missoffe, "Talleyrand et Maret, duc de Bassano, lettres inédites," *Revue des deux mondes* (August 1954); H. Huth and W. J. Pugh, *Talleyrand in America as a Financial Promoter, 1794–1796*, 3 vol. (1942).

**Biographies:** The standard work is G. Lacour-Gayet, *Talleyrand, 1754–1838*, 4 vol. (1928–34). E. L. Dard, *Napoléon et Talleyrand 1935*; Eng. trans. by C. R. Turner, 1937, is based extensively on the Austrian archives. More recent but less original biographies are by A. Duff Cooper (1932); French trans. by H. and R. Alix, 1937); C. Crane Brinton (1937); the comte de Saint-Aulaire (1936); L. Madeiran (1944); J. Bertaut (1945); R. Laforgue (1947); M. Missoffe (1956); E. Tarlé (1958). (J. Go.)

**TALL HALAF** (TELL HALAF), an ancient north Syrian city lying on the west bank of the Khabur River, 3 mi. NW of Ras-al-Ain, not far from the Turkish border. Populous and important both in the prehistoric period and during the 1st millennium B.C., when it was an Aramaean centre (Bit-Bahiani), it was the Gozan of the Old Testament (II Kings 17:6), to which the Israelites were deported in 722 B.C. after the capture of Samaria by the Assyrians. The place was excavated by a number of German expeditions under the direction of Baron Max von Oppenheim between 1899 and 1927. At its fullest extent, in historic times, the city occupied about 150 ac. and was enclosed by lofty mud-brick walls which were protected by towers and bastions on three sides and by the river on the fourth.

The settlement was already flourishing in the 5th millennium B.C. and has yielded black and gray Neolithic monochrome pottery as well as a typical flint and obsidian blade industry and polished ground-stone celts. A series of typical north Syrian painted ceramic followed: the finest are vessels decorated in a lustrous paint on a shiny surface with geometric and animal designs. This attractively fashioned pottery has been named Tall Halaf ware

from the primacy of its discovery on this site, although a greater range of it, properly stratified, was subsequently found at Arpachiyah near Nineveh. Seated figurines of a "mother goddess," also painted; models of cattle; designs of bucrania (ornamented ox skulls); and painted onagers were also characteristic. Evidence of the subsequent Ubaid Period has also been recovered from Halaf.

Although the site was no doubt continuously occupied, little is known about it in the long interval between the prehistoric period and the 9th century B.C. The first historic mention of the city (as Guzana) occurs in the reign of the Assyrian king Adad-nirari II, who exacted tribute from its ruler Abi-salamu; Ashurnasirpal II also marched against it, and in 808 B.C. Adad-nirari III sacked the city and reduced the district to a province of the Assyrian Empire.

The only known local ruler was an Aramaean prince named Kapara (c. 825 B.C.), who built a temple and a palace and caused his name to be inscribed on a series of basalt orthostats which adorned the walls of the temple-palace. The most notable architectural monument in Gozan was a *bit hilani* building—i.e., one with a portico supported by pillars consisting of life-size caryatid stone figures of divinities mounted upon lions. A remarkable figure of a goddess carrying a bucket, with handle of Assyrian type, bears an inscription which proclaims that anyone defacing it shall be accursed by having his seven daughters indentured to Ishtar and his seven sons burned before the weather god. The city prospered in the 8th and 7th centuries B.C. when it was directly administered by resident Assyrian governors. Seleucid remains, including houses, baths, and graves, were found in the citadel. See also ARAMAEANS; BABYLONIA AND ASSYRIA: *Archaeology, Architecture and Art*.

**BIBLIOGRAPHY.**—*Tell Halaf*, vol. i, ed. by Hubert Schmidt (1943), vol. ii, ed. by R. Naumann (1950), vol. iii, ed. by A. Moortgat (1955); M. von Oppenheim, *Der Tell Halaf, Eine neue Kultur im ältesten Mesopotamien* (1931), Eng. trans. by G. Wheeler (1933). (M. E. L. M.)

**TALLIEN, JEAN LAMBERT** (1767–1820), French revolutionary who became a leader of the moderates (Thermidorians) after he had helped to engineer the fall of Robespierre in 1794. He was born in Paris on Jan. 23, 1767. In 1789 he became secretary to a member of the Third Estate in the Estates-General, and then a foreman in the printing house that published the newspaper *Moniteur*. In August 1791 he brought out a wall newspaper, *L'Ami des Citoyens*, which was subsidized by the Jacobin Club. After taking part in the insurrection of Aug. 10, 1792 (see FRANCE: *History*), he became secretary to the Commune of Paris. This was the real beginning of his political career.

It is possible that he had some responsibility for the September massacres of 1792, which he later defended in his pamphlet "La Vérité sur les événements du 2 septembre" (1792). Elected for the *département* of Seine-et-Oise to the National Convention, he sat with the Montagnards and opposed the Girondins (*q.v.*). During the trial of Louis XVI (December 1792–January 1793) he voted against a plebiscite and any postponement of the death penalty. He became a member of the Committee of General Security, and on March 9 was sent on a mission to organize recruiting for the army.

His most important mission was to the *départements* of the southwest, particularly to the Gironde. With Claude Ysabeau, he raised a revolutionary army and on Oct. 19, 1793, captured Bordeaux, which had rebelled during the federalist insurrection (see VENDÉE, WARS OF THE). Tallien immediately appointed a military commission to try those responsible, and levied a tax on the rich. But on 28 Brumaire year II (Nov. 18, 1793) he was denounced in the Committee of General Security for "his liaison with Madame Cabarrus, the divorced wife of the ex-noble Fontenay"; he had previously released her from prison in Bordeaux. Nevertheless at the end of December his mission was confirmed. Tallien was recalled to Paris in March 1794. He survived Robespierre's purge of the Jacobins on 23 Ventôse (March 13) and at first supported the Committee of Public Safety, approving the execution of Jacques Hébert and Georges Danton. But on 3 Prairial (May 22) the Committee ordered the arrest of Madame Cabarrus, who had followed Tallien to Paris, and he became its enemy. On

June 12 Robespierre denounced him. Feeling himself in danger, Tallien conspired with Paul Barras, Louis Fréron, Joseph Fouché, and others, and was one of the most active in Robespierre's fall on 9 Thermidor (July 27), when he prevented Louis Saint-Just from making his speech in defense of Robespierre.

From this time, Tallien was one of the important men in the Convention, and a leader of the so-called Thermidorian reaction. A member of the reconstructed Committee of Public Safety, he set Madame Cabarrus free on 25 Thermidor (Aug. 13) and married her on 6 Nivôse year III (Dec. 26). Tallien supported the attack on the members of the government Committees of 1793–94, who were tried and deported, and on 16 Germinal (April 5, 1795) decreed the arrest of all his enemies, the former Montagnards. After the abortive royalist rising of 13 Vendémiaire year IV (Oct. 5, 1795) he also denounced some of his colleagues for royalist sympathies. When the Directory was set up (November 1795) he became a member of the Five Hundred, but, suspected now by all parties, he no longer had any influence. He retained his seat until 1798 when he accompanied Bonaparte to Egypt. On his return (April 1801) he found his wife had finally left him; they were divorced in 1802. Supporting the first Restoration (1814) of Louis XVIII, then the Hundred Days, he was deprived of his pension at the second Restoration (1815) and lived in poverty. He died in Paris on Nov. 16, 1820. (A. So.)

**TALLINN** (German *REVAL*), a primary seaport and capital of the Estonian Soviet Socialist Republic, U.S.S.R., lies on the north coast and on the Gulf of Finland opposite Helsinki. The population (1959), including the suburbs of Nõmme and Piritä, numbers 281,714, a third of whom are Russians.

The foundation of Tallinn is ascribed to the Danish king Valdemar II, who in 1219 built a citadel on the site of a former Estonian stronghold. As merchants from the Baltic ports of Visby, Lübeck, and Bremen settled there in the 13th century, the town prospered and became a port and trading centre of the Hanseatic League (*q.v.*). Valdemar IV sold Tallinn to the Teutonic Knights in 1346, but on the dissolution of the Teutonic Order in 1561, the town surrendered to the Swedish king Eric XIV. Its trade was gradually destroyed, first by a great conflagration in 1433, then by a pestilence in 1532, and finally by a series of prolonged wars. The town was bombarded from the sea by the Danes in 1569 and was besieged by the Russians in 1570 and 1577. In 1710 Tallinn surrendered to Peter the Great, who later constructed a port there for his Baltic fleet. The town passed from Russian to Estonian rule in 1918, but fell under Soviet occupation in 1940, only to be taken by the Germans a year later. Tallinn suffered heavy bombardment by the Russians in March 1944, with almost a third of the homes destroyed, as well as the port and many ancient structures. On Sept. 22, 1944, Soviet troops took Tallinn.

After World War II the harbour was reconstructed as a port for the Soviet fleet. The town has become a major industrial and cultural centre. Its main industries include shipbuilding, engineering (radios, motors, and electrical and other machinery), cotton textiles, paper and pulp milling, and manufacture of cellulose and furniture. Though many new buildings dominate the town, the remains of the ancient citadel and the city wall with its many towers form a picturesque setting. An art museum houses a fine collection of modern Estonian painting and sculpture, and there are polytechnical and pedagogical institutes and schools for music and fine arts.

**TALLIS, THOMAS** (c. 1505–1585), the most important English composer of sacred music of the generation preceding that of William Byrd. Nothing is known of his education. In 1532, however, he held a post at Dover Priory and in 1537 at St. Mary-at-Hill, London; and his name appears in a list of persons who in 1540 received wages and rewards for services at the dissolution of Waltham Abbey in Essex. From Waltham he appears to have gone briefly to Canterbury and then to the Chapel Royal. In a petition to Queen Elizabeth I made jointly with William Byrd in 1577 he refers to having “served your Majestie and your Royall ancestors these fortie years,” but his appointment as a gentleman of the Chapel Royal can hardly have been before 1542. The same document refers to one only previous instance of preferment and

that, interestingly, from the hand of “your Majestie's late deare syster quene Marie.” This was a 21-year lease of the manor of Minster in the Isle of Thanet (Kent) granted in 1557 to Tallis and Richard Bowyer, Master of the Children.

On Jan. 22, 1575, Queen Elizabeth granted Tallis and Byrd the monopoly for printing music and music paper in England. This gesture of royal favour to the two musicians, who were at this time joint organists of the Chapel Royal, did not at first operate to their advantage. The above-mentioned petition of 1577 seeks relief, in the form of an additional lease, for the loss of 200 marks incurred during the first two years. The lease was granted.

The first publication under their licence was a collection of 34 motets, 17 by Tallis and 17 by Byrd, entitled *Cantiones sacrae* printed by T. Vautrollier in 1575. These Latin pieces, together with 5 anthems to English texts printed by John Day in his *Certaine Notes . . .* (1560–65), comprise all of his music that Tallis saw in print during his lifetime.

The latter years of his life were spent in Greenwich, where he died on Nov. 23, 1585. According to his epitaph Tallis was married “ful thre and thirty Yeres” (*i.e.*, in 1552) but had no children. His wife, Joan, who died in 1589, was buried in her husband's grave.

Tallis' long life spans a period that saw important changes in English music: changes of style between the generations of Taverner on the one hand and Byrd on the other, changes necessitated by the introduction of an English liturgy (which, however, did not entirely replace the Latin), and the development of an impressive school of keyboard composition. A substantial amount of Tallis' music remains, among which most of the forms of his day are represented. His Latin works include a modest, unnamed 4-part Mass; a 5-part Mass, *Salve intemerata*, skillfully derived from his antiphon of the same name; and a 7-part Mass, long known only from a number of sections and regretted as lost, which has now been entirely restored. There are also two settings of the *Magnificat*, one of 4 parts and one of 5, a comparison of which illustrates the contrast between the old and the new styles in Latin music which coexisted for a time in the mid-16th century. Tallis also made two settings of the *Lamentations of Jeremiah*; the first, especially, is among his finest works. An important part of Tallis' catalogue of works consists of two groups of compositions, one of Responsory settings, the other of Office hymns, forms in which his contribution is matched, among his contemporaries, most notably by the numerous similar settings by John Shepherd. Finally among his Latin pieces, two in particular stand as demonstrations of Tallis' supreme mastery of the art of counterpoint: the 7-part *Miserere nostri*, an extraordinary feat of canonic writing, involving retrograde movement together with several degrees of augmentation; and the famous 40-part *Spem in alium*, a unique monument in British music, scarcely rivaled even by Robert Carver's 19-part *O bone Jesu*. Set out for eight 5-part choirs, *Spem in alium* is a remarkable demonstration of contrapuntal resource, a thoroughgoing example of imitative writing seemingly not at all limited by the scale of the work. What could have been Tallis' purpose in writing such a work, the performance of which would have been (and is) possible only under the most exceptional circumstances, is a mystery. But that it is a work of art, not merely a technical feat, is unquestionable.

Tallis, as a gentleman of the Chapel Royal at the time of the introduction of the Book of Common Prayer, was one of the first composers to provide settings of the English liturgy. He has left settings of the Preces and Responses, the Litany, and a complete Service “in the Dorian mode” which consists of the morning and evening canticles and the Communion Service, including the *Gloria*, which later ceased to be set. There are also three sets of psalms, several psalm tunes for Archbishop Matthew Parker's Psalter (printed in 1567 or 1568 but withheld from sale), and a number of anthems. Although some of these are adaptations to English texts of Latin compositions, several are found in 16th-century sources and therefore, perhaps, are the work of the composer himself or were at least sanctioned by him. Apart from adaptations there exist also a number of original settings of English words.

Tallis' secular vocal music is negligible and his music for instru-

mental ensemble virtually so, but his keyboard music is substantial and significant. This includes both sacred and secular pieces, extended *cantus firmus* compositions, and arrangements of vocal works. Of his 23 extant keyboard pieces 18 occur in the mid-16th-century manuscript known as the Mulliner Book.

Tallis' Latin church music was published in *Tudor Church Music*, vol. vi (1928). His keyboard music is to be found in *Musica Britannica*, vol. i, "The Mulliner Book" (1951), and *Tallis: Complete Keyboard Works* (1953), both edited by Denis Stevens.

**BIBLIOGRAPHY.**—H. B. Collins, "Thomas Tallis," *Music and Letters*, x (1929); L. Ellinwood, "Tallis' Tunes and Tudor Psalmody," *Musica Disciplina*, ii (1948); D. Stevens, "The Keyboard Music of Thomas Tallis," *Musical Times*, xciii (July 1952). (Jo. D. B.)

**TALLY**, a primitive instrument of accountancy, consisting, in its developed form, of a narrow stick or strip of hard wood, notched along one edge or along two opposite edges, for about three-quarters or two-thirds of its total length, with notches representing quantities, and then split from one end through all the notches down to a transverse incision made halfway through it at about one-quarter or one-third of its length from the opposite end. The smaller, flat part thus detached is called the foil, or countertally; the larger part, with the unsplit end, is called the stock. Since the notches on stock and foil are complementary, the parties to a transaction, one of whom takes the stock and the other the foil, have a record which neither can vary without the other's agreement. Writing on the tally summarizes its notching and specifies its purpose. In the most primitive form, however, a notched stick serving merely to remind one of the progress of an account or "score" may be called a tally.

The chief interest of the tally centres on its official use in England, where, in the Middle Ages, it became the basis of government finance and one of the earliest negotiable instruments. Its official use in England is earlier even than the very early "exchequer" organization (see **EXCHEQUER**); soon after 1100 it was a settled system—a system, moreover, carefully differentiated from any private one and used for money only; and the tally continued to be the recognized form of receipt for payments into the Royal Treasury down to 1826. Though there were modifications of wording, the regular form of the Exchequer tally changed little save for a continually increasing length: the original 9 in. was extended in one extreme example (preserved at the Bank of England) to 8 ft. 6 in.

See H. Jenkinson, articles in *Archaeologia*, lxi and lxxiv (1911, 1924); A. Steel, *The Receipt of the Exchequer, 1377-1485* (1954). (H. J.E.; X.)

**TALMA, FRANÇOIS JOSEPH** (1763-1826), French actor, a rebel in politics and in art, was born in Paris on Jan. 16, 1763. He made his debut at the Comédie Française on Nov. 21, 1787, as Seide in Voltaire's *Mahomet*. Influenced by his friend the painter David, Talma became one of the early advocates of historical costuming when he appeared in a Roman toga and head-dress in the small role of Proculus in Voltaire's *Brutus*. He found his great opportunity in Joseph Chénier's antimonarchical *Charles IX*, which caused demonstrations in the theatre and aroused such dissension within the company that republican Talma established a rival troupe, known as the Théâtre de la République, on the site of the present Théâtre Français. There Talma developed realism in staging and costuming. When the two companies were reunited in 1799 at his theatre as the Comédie Française, Talma emerged as the supreme tragedian of the era. In both his scenic reforms and his acting, Talma was a leading precursor of 19th-century French romanticism and realism. His artistic credo was "grandeur without pomp, nature without triviality." Talma died in Paris on Oct. 19, 1826.

Talma wrote *Reflections on the Actor's Art* as a preface to the *Mémoires de Lekain* (1825). (H. K. Cy.)

**TALMUD** (Heb. "learning"), a compilation that was revered by the Jews as a sacred book from the time it was compiled down to the 18th century, the laws expounded therein being considered of divine origin on a par with those in the Torah (*q.v.*). After the emergence of the *Haskalah* (Enlightenment) movement in the 18th century, and later upon the rise of the Reform movement, many

Jews ceased to think of it as divinely inspired, though they continued to regard it as of great value for the study of Jewish history, law, theology, folklore and ethics. A large segment of the Jewish population continues to regard the laws set forth in the Talmud as having been given by God, and the power of thought displayed in it by the Jewish sages of antiquity inspires profound respect in all students.

The Talmud comprises two main sections, the Mishna and the Gemara (the latter often called Talmud also), plus some additional laws called Baraitoth and passages from another collection called Tosefta. The Mishna ("repetition") is a lawbook, the work of the sages who lived in Palestine before the destruction of the Second Temple (A.D. 70) and a century and a half thereafter. The Gemara ("completion"), a commentary on the Mishna, is the work of later sages, the *amoraim*. The Talmud deals, in the main, with legal matters, and this part is called *halakha* (pl. *halakhoth*; "law"); the nonlegal part is called *haggada* ("saying," "narrative"). The *halakhoth*, the laws embodied in it, are based on Oral Law.

The Talmud is a storehouse of law, religion, history, ethics, metaphysical speculations, medical science, astronomy, and folklore. It is an encyclopaedia covering every phase of human activity, a mine of information for the study of religion, history and civilization not only of the Jews but of the peoples of the entire middle east. It is important for a proper understanding of the origin of Christianity, since this literature came from men who taught at the time when Jesus lived. It is essential for comprehension of the controversies over the law between the Pharisees and Jesus as recorded in the Synoptic Gospels.

For the Jews the Talmud was not merely a lawbook, regulating life; its discussions, being divinely inspired, were the purpose and essence of life itself. When the Jews were persecuted and driven from public life during the middle ages, they found consolation in the study of the Talmud. It stimulated and cultivated their minds, saving them from stagnation. By its study they were assured of a reward in the future world, and this conviction was a religious incentive to every Jew. In the middle ages, when the great majority of the European population was illiterate, the Jews were saved from total ignorance by their intense devotion to the study of the Talmud.

## ORAL LAW

**Traditional Laws.**—The Jewish people, like other peoples, in early times had unwritten as well as written laws. The written laws are those in the code called the Torah, the Pentateuch. But in the writings of the prophets as well as in the Hagiographa (*i.e.*, the Old Testament books exclusive of the Pentateuch and the Prophets) there are references to customs and laws that are not found in the Pentateuch. In the book of Jeremiah, for example, it is stated that when the prophet bought a field from Hanamel he wrote a deed in the presence of witnesses who affixed their signatures. There is no mention in the Pentateuch of the requirement of a deed and witnesses in the transfer of real property. In the book of Ruth it is said that Boaz told his kinsman that he would have to marry Ruth when he purchased the field from Naomi "in order to restore the name of the dead to his inheritance" (iv, 5). It is further stated that this was the custom "in former times in Israel concerning redeeming and exchanging: to confirm a transaction, the one drew off his sandal and gave it to the other, and this was the manner of attesting in Israel." This custom of transferring immovable property by the symbolic act of drawing off the shoe is not mentioned in the Pentateuch.

In ancient times, if a man did not pay his debts, his creditor had the right to take him into servitude; if he died and left the debt unpaid, the creditor could enslave his children. This is shown by a passage in II Kings (iv, 1) in which a woman cries to Elisha, "Your servant my husband is dead; and you know that your servant feared the Lord, but the creditor has come to take my two children to be his slaves." This law is not mentioned in the Pentateuch.

It is evident from the book of Genesis that among the early Hebrews a man had to purchase his wife from her father. Jacob

paid Laban in manual labour for the right to marry his daughters; David paid Saul 200 foreskins of the Philistines for the right to marry his daughter Michal. Yet the Pentateuch makes no reference to bride price. Nor is any writ in connection with marriage referred to in the Bible; nonetheless a custom of writing marriage documents prevailed among the early Hebrews. Such a document is recorded in the Elephantine papyri. Also, in the book of Tobit, it is said that when Raguel gave his daughter Sarah to Tobias he called her mother, "took a scroll and wrote out the contract; and they set their seals to it" (vii, 14).

The unwritten laws were as old as, and perhaps older than, some of those embodied in the Pentateuch. The sages of the Talmud recognized this when they said that thousands of laws or customs were forgotten during the time of mourning for Moses. Such nonpentateuchal laws came to be known as *halakhoth*, *torah shebe-al pe*, "Oral Law," while the laws of the Pentateuch were described as *torah shebikthab*, "written laws."

The unwritten law has been considered holy by all peoples. Sophocles made Antigone justify the burying of Polynices, against the order of King Creon, on the basis of "the immutable unwritten laws of god. They were not born today nor yesterday; they die not; and none knoweth whence they sprang." Aristotle spoke of written and unwritten laws, the latter of which were based upon nature and universally recognized. Philo, in his *Special Laws*, wrote, "For customs are unwritten laws, the decisions approved by men of old, not inscribed on monuments nor on leaves of paper which the moth destroys, but on the souls of those who are partners in the same citizenship." He differentiated between written and unwritten laws, stating, "Praise cannot be duly given to one who obeys the written laws, since he acts under admonition of restraint and the fear of punishment. But he who faithfully observes the unwritten deserves commendation, since the virtue which he displays is purely willed." Aristotle reflected a similar opinion in the *Rhetoric*.

**Pharisees and Sadducees.**—According to Josephus, who is upheld by the tannaitic literature, the Sadducees denied the authority of the Oral Law while the Pharisees adhered to it. But the Sadducees could not reject all the laws that were not mentioned in the Pentateuch, since no state can function without custom. The cleavage between the Pharisees and the Sadducees was due to the fact that the former maintained that the Oral Laws were as binding as the written laws and that transgressors of the unwritten laws should be punished as were those who transgressed the written laws. The Sadducees denied this, on the ground that the unwritten laws were less binding than the pentateuchal laws. The Pharisees also maintained that the pentateuchal laws must be amended and interpreted so as to conform to the changing culture and economic condition of the people; the Sadducees rejected such innovations. (See JEWISH SECTS DURING THE SECOND COMMONWEALTH: *Pharisees; Sadducees*.)

**Revisions and New Laws.**—In the course of time, however, all laws, written and unwritten, become outmoded. Some device or institution is needed to provide for amendment and interpretation in order to bring them into consonance with contemporary life. In the Jewish second commonwealth period such an institution was developed—the Sanhedrin (*q.v.*).

Before the Hasmonaean period the Jewish government was a theocracy. Religious authority was vested in the high priest, the representative of God. Theocracy was abolished after the establishment of the commonwealth, and nomocracy (the rule of the law) was instituted in its stead. A *bet din* ("court"), commonly known as Sanhedrin, was inaugurated in 141 B.C., with authority to interpret the pentateuchal laws and to enact the unwritten laws into statutory laws. Further, new laws were added by the *soferim*, "scribes," of the Sanhedrin (see SCRIBES). Rabbi Joshua said that certain new laws were introduced by the *soferim*, "and I cannot gainsay them" (*Tebul Yom* 4, 6). The *soferim* also modified the pentateuchal laws, holding that their modifications were in the tradition of the fathers. They amended, for example, the pentateuchal law concerning levitical purity. According to the Pentateuch, ritual cleansing could not be completed till after sunset. In later times this worked great hardship on the

people, interfering with their daily lives. The sages therefore declared that the law applied only to priests in the matter of eating the sacred food. But the requisite of washing the whole body still worked hardship, so the sages reduced it to a mere washing of the hands before meals. Reference to this law is made in the Synoptic Gospels, where it is described as the "tradition of the elders."

It is stated in the Pentateuch that a Jew may not carry a burden on the sabbath, but Oral Law specified that things may be carried in the house. According to the Pentateuch cattle must be slaughtered before their flesh is eaten, but the method of slaughtering is not described; the Oral Law defines ritualistic slaughter as cutting the throat.

In some cases Oral Law took precedence over the written law or even nullified it. The Pentateuch states that the blood of a fowl should be covered with sand, but according to the Oral Law it may be covered with anything that happens to be at hand. The sages took cognizance of the fact that the Oral Law expresses the spirit of the law, namely that the blood be covered.

**Civil Law.**—Civil as well as religious laws in the Pentateuch are so ambiguous and narrow that no civilized society could have been governed without the Oral Law, which supplemented and interpreted the pentateuchal laws, making them adaptable to changing conditions and expressive of the evolving views of society. There are laws in the Pentateuch regarding damages and injury, but there are no specifications of gradations in torts, injuries and liabilities. No law is given regarding damages that are not discernible. For example, a person might mix another person's wheat with "sacred wheat," making it impossible for the second man to use it and thus causing a financial loss; yet the damage was not recognizable in pentateuchal law. According to the Oral Law, however, the person committing this act was obligated to pay for the damages he caused.

The laws of partnership, of the means of acquiring property and of personal agency are not dealt with in the Pentateuch but are based on Oral Law. The pentateuchal laws dealing with inheritance, for example, assumed the inalienability of bonded property from the possession of the tribe. When a person dies his estate is inherited by his sons; where there are no sons it passes to his daughters, and where there are no daughters it goes to the nearest kin. It must always remain in the family or the tribe. The idea of testament is not found in the Pentateuch for the simple reason that the Pentateuch does not recognize that property may be transferred to a stranger. The Oral Law took cognizance of changed social conditions and gave a person the right to write a will devising part of his property to anyone, even to a stranger. According to the Oral Law, man is immortal but the title to property is limitable by time. A man may stipulate that his will take effect after his death and the court is obligated to carry out his bequest.

No reference is made in the Pentateuch to writs, whether in connection with property transactions or loans. It is clear from papyri that as early as the 5th century B.C. a debtor gave his creditor a note in which he not only obligated himself to pay the debt but also gave the creditor the right to seize his property if the debt was not paid; if the debtor died before the loan was paid his children had to pay it. The right of seizure of a debtor's property was based on the unwritten law, and the promissory note nullified the biblical laws that gave the creditor rights over the person of the debtor and his children.

Use of promissory notes also modified the pentateuchal law in connection with the sabbatical year. The Pentateuch clearly specifies that a debt that outlasts the sabbatical year can no longer be collected. To encourage loans to the needy, Hillel introduced the *prosbol* (derived from the Greek *pros boule*, "before the council"), in which the creditor deposited with the court a note stating that a debt owed him by A might be collected at any time the creditor chose. The creditor thus secured his debt against the provision of the pentateuchal law concerning the sabbatical year. A loan for which no note was given was forfeited if not paid before the year of release.

The Pentateuch refers twice to the *lex talionis*, an eye for an eye, a tooth for a tooth (Ex. xxi, 24; Lev. xxiv, 20), but injury

and bodily mutilation as well as theft were considered private wrongs. It was not for the state to punish the offender; the matter was to be settled between the person who inflicted the injury and the one injured. The man who suffered the loss of an eye or any other member of his body could absolve entirely the man who caused the injury or could demand any satisfaction, even to taking out the eye of the man who caused the loss of his eye. *Talio* was the extreme satisfaction the plaintiff might demand, but it was not mandatory; the injured person could obtain satisfaction with money if he so wished. On the principle that two different persons could not have exactly the same members of the body, the sages enacted a law by which the injured man could not demand an eye from the person who caused the loss of his eye but that he could demand the value of his eye. In this way, the *lex talionis* was abolished.

**Shammaites and Hillelites.**—The sages of the commonwealth endeavoured not only to interpret the pentateuchal laws so as to bring them into consonance with contemporary life but also to incorporate some of the old *halakhoth* into statutory laws—in other words, to make them written laws in order that they might be used as a basis for deducing new laws in accord with the demands of the times. Two schools of thought arose in regard to the soundness and the validity of interpreting the pentateuchal laws and the *halakhoth*. One, the Shammaites, represented the conservative, the other, the Hillelites, the liberal point of view. They were named after the great sages Shammai and Hillel (*q.v.*), the fifth and last of the *zugoth* ("pairs"), or joint heads of the Sanhedrin. Every sage enrolled himself as a Shammaite or as a Hillelite, and the two schools, which arose with the establishment of the commonwealth, continued until the time of the compilation of the Mishna.

To establish a legal system by which the pentateuchal laws could be interpreted, and to legalize the modification, Hillel applied three hermeneutic devices. These are (1) *kal wa-homer*, inference *a minori ad maius*, from the less important (law) to the more important (law); (2) *gezerah shawah*, inference by analogy of words; and (3) *hikish*, inference by analogy of subjects. These three principles were not introduced by Hillel, but it was he who organized them into a juristic discipline by which the entire pentateuchal law could be interpreted. Later the three were developed into seven, and Rabbi Ishmael, who lived after the destruction of the Second Temple, increased them to 13. In accepting the hermeneutics as a legal system the sages found it necessary to limit them in certain ways. In regard to penal law, for example, the inference from *a minori ad maius* could not be applied; no penalty could be inflicted that was based upon an inference. Again, the principle of inference could not be made from a *halakha*; it was applicable only to the laws of Scriptures and to those *halakhoth* that had become statutory.

The method of interpretation of the pentateuchal laws was called *Midrash Mikra* and that of interpretation of the old *halakhoth* was called *Midrash Halakhoth*. The sages who interpreted the pentateuchal laws were called *darshanim*, "interpreters," and the place where they assembled was known as the *Bet ha-Midrash*.

The idea of intention as a legal principle was the great innovation introduced by Hillel. An act without intention, although willed, was not considered a legal act. For example, if a man gives a ring or money to a woman, this does not make her his wife. The consummation of a marriage requires intention. The man has to give the ring to the woman with the intention of marrying her by open declaration. Hence, according to talmudic law, marriages of minors and lunatics are invalid, since such persons cannot exercise intention. The principle of intention had a far-reaching influence on all Jewish laws, ritual, civil and criminal. Shammai and his school strongly opposed this innovation, but it became an integral part of the legal system of the Talmud.

**Rabbon and Tanna.**—With the liberal views of Hillel prevailing among the sages, there came a change in the leadership of the Sanhedrin. Previously two men had headed this institution, the *nasi* and the *ab bet din*. The office of the latter was now abolished. Gamaliel (*q.v.*), grandson of Hillel, became the sole leader of the Sanhedrin, with the title *rabbon*, "our *nasi*" (*rabba*

being the Aramaic form of *nasi*). The sages who interpreted the law were called *soferim*, "scribes," before the destruction of the Second Temple, and this term occurs in the Gospels; no title was appended to their names. After the destruction of the Temple the sages came to be called *tannaim*, and those who received authorization had the title *rabbi*.

The *tannaim* were jurists, as is exemplified in the *halakhoth* with regard to *jus in personam* and *jus in rem*. They held that the law was made for man and not man for the law. They maintained that society cannot be governed without law, and that the purpose of law is to prevent men from doing what is wrong and to punish violators. They held however that equity should be applied to decisions and leniency should take precedence over strictness in the application of the law. The *tannaim*, who were the spiritual leaders of the people, aimed to promote the general welfare by regulating the relations between man and God and between man and man.

## THE MISHNA

After the destruction of Jerusalem by the Romans in A.D. 70, Jabneh (modern Jamnia, located on the Judean plain of western Israel), under the leadership of Johanan ben Zakkai, became the centre of Jewish learning. With the collapse in A.D. 135 of the Bar-Cochba revolt, which led to the virtual decimation of the Judean population, the centre was moved to Usha in Galilee (near modern Haifa). (See YESHIVA.) During this momentous period in the history of the Jews the sages decided that the *halakhoth* should be assembled and codified. There was disagreement as to how the collection should be organized, one school holding that the *halakhoth* should be collected in the order of the biblical verses from which they were interpreted, the other maintaining that they should be arranged according to the subject matter. The view of the latter school prevailed, and the assembling of the *halakhoth* on this plan, begun by Rabbi Akiba ben Joseph, was continued by his disciples (especially Meir) and completed in the early part of the 3rd century A.D. by Rabbi Judah ha-Nasi, the Prince, known as *rabbi par excellence*. This collection of the *halakhoth* was called *Mishna* (Gr. *Deuterosis*), second to the Torah (the word is variously transliterated also as *Mishne* and *Mishnah*). Soon after its completion it became the standard work for further interpretations of the *halakhoth* and was revered as second only to the Bible. The halakhic decisions in the *Mishna* became binding.

**Orders of the Mishna.**—The *Mishna* is divided into six "orders" (*sedarim*), each order into tractates (*massekhtoth*), and each tractate into chapters (*perakim*). The *sedarim* are as follows:

1. *Zeraim* ("seeds"), 11 tractates. The first tractate, called *Berakhoth*, deals with worship and treats of benedictions and prayers and the time of the reading of the *shema*. In other tractates the biblical precepts are set forth relating to the rights of the poor, tithes given to the priests and the Levites, rules and regulations connected with agriculture and the laws connected with the sabbatical year.

2. *Moed* ("festivals"), 12 tractates. In this order the laws in connection with the sabbath and the festivals are set forth. One tractate is devoted to the laws connected with fasts. Another, *Shekalim*, treats of the half-shekel which every Jew had to contribute to the Temple.

3. *Nashim* ("women"), 7 tractates. This order deals with the laws of marriage and divorce and Levirate marriage and divorce. Also given are the regulations governing the relations between husband and wife and between the sexes in general. In this order the tractate *Nedarim* treats of vows and their annulment. Another tractate, *Nazir*, gives the laws concerning Nazirites.

4. *Nezikin* ("damages"), 10 tractates. The first tractate, called *Nezikin*, is divided into three parts: *Baba Kama* ("first gate"), in which the laws of damages and injuries and those regarding theft and robbery are set forth; *Baba Metsia* ("middle gate"), which treats of laws concerning found property, usury and hired labour; and *Baba Bathra* ("last gate"), which deals with *hazakah* (usucapion), the laws regarding the sale and purchase of immovable and movable property, and the laws of partnership and inheritance. *Sanhedrin* ("court") concerns the composition of the

court and trial procedure, with the different punishments for various offenses, with the principle of *corpus delicti* and with the laws of arbitration. *Makkoth* ("stripes") deals with the lashings to which a person is condemned by a court. *Shevuoth* ("oaths") treats of the different kinds of oaths, those made in private life and those administered in court. *Aboda Zara* ("idolatry") treats of the laws concerning idols and the relation to idol worshippers. Two other tractates that bear no relation to the main subjects are included in this order: *Eduieth* ("testimonies"), a collection of traditional laws; and *Pirke Aboth* ("sayings of the fathers"), or *Aboth*, a collection of ethical maxims of the sages.

5. *Kodashim* ("holy things"), 11 tractates. This order, devoted to the subject of sacrifices, contains the tractates *Tamnid* ("daily sacrifice") and *Middoth* ("measurements"), which describe the daily sacrifices of the morning and of the evening, and of the area of the Temple, its courts, gates and the daily services of the priests and the Levites.

6. *Taharoth* ("purifications"), 12 tractates. It sets forth the laws of ritual cleanliness and uncleanness, both in persons and in things, and the laws in connection with purifications. The tractate *Yadayim* ("hands") is devoted to the laws in connection with the ritual impurity of the hands, their defilement of the Holy Scriptures. In this tractate is related the controversy in regard to the canonicity of Ecclesiastes and the Song of Solomon.

**Character of the Mishna.**—The Mishna is a code of *halakhoth* consisting of religious laws and laws governing society. These *halakhoth* in general are not based on the Pentateuch; biblical texts are not quoted to substantiate the *halakhoth*. In *Baba Bathra*, which consists of ten chapters dealing with civil law, there is not a single reference to the Bible. References are made to biblical verses only in some chapters of a few tractates, and this practice can be traced to the Midrash form applied by many sages in interpretation of *halakhoth*.

Two orders—*Kodashim*, which treats of sacrifices, and *Taharoth*, which sets forth the laws of ritual cleanliness and uncleanness—are concerned with matters that had become obsolete. They were included in the Mishna because, first, many of the tractates had already been compiled before Rabbi Judah's time, and, second, the Jews of the period had complete confidence that before long the Temple would be rebuilt and sacrifices restored.

Because the tractates were compiled at various different times, the Mishna shows a lack of consistency. The unevenness of the Hebrew language also can be attributed to the fact that it represents many periods of antiquity and of post-Hadrianic times. The sequence of many tractates within each order is of a later era and is mechanical. Rabbi Judah did not set the sequence.

The Mishna, being a code, does not contain *haggadoth*, legends such as occur in the tannaitic literature and in the Talmud (see below, *The Talmuds*). Messianic and eschatological ideas that were prevalent among the Jews of the time of its compilation are largely ignored. It is stated that those who do not believe in the Revelation and those who deny resurrection (spiritual) will not share in the future world. No mention is made of those who deny the coming of the Messiah. No reaction may be seen in the Mishna toward the Christians in general, or, with one exception, toward the Jewish Christians. In the tractate *Berakoth* it is stated that, by law, when a Jew greets another Jew he should pronounce the Name, the Tetragrammaton, although pronouncing the name of God is prohibited in the Pentateuch (e.g., Ex. xx, 7, "You shall not take the name of the Lord your God in vain"). Jewish Christians, on meeting their fellow Christians, greeted them, "Peace in the name of God and the Lord Jesus Christ." The sages, disregarding the injunction of the Pentateuch, introduced a law requiring pronunciation of the Tetragrammaton in order to signify that there is one Lord and that he is God, and that Jesus was not the Messiah; furthermore, this greeting would reveal believers in Jesus.

It may be asked, if the Mishna is a *corpus juris*, why does it contain divergent opinions in connection with the laws? The answer is that Rabbi Judah believed that the opinions of the minority as well as of the majority should be recorded, even though the decision of the law had to follow the majority opinion. The minority opinion was included so that if at some future time new laws

were enacted the rabbis would be able to find support for their decisions in these minority opinions. When Judah thought that the decision of the law should follow the opinion of one particular sage he recorded his opinion anonymously or in the name of the sages; i.e., he stated it as a majority opinion. Other principles were laid down regarding decisions of the law; for example, when there was a controversy between the schools of Shammai and Hillel, the law was decided in accordance with the latter.

The Mishna, though a code, cannot be compared to the Pentateuch, which was believed to be revealed by God to Moses and had to be administered by a high priest, a vicar of God. Nor can it be compared to the code of the Roman law: the sages did not derive their authority from secular rulers or magistrates; it was based rather on their profound knowledge of the law and ability to interpret it, and on the authorization received from their spiritual mentors, which, according to tradition, came down unbroken from Moses.

**Writing of the Mishna.**—A divergence of opinion exists with regard to the compilation of the Mishna. Many rabbis of the middle ages, particularly of Spain, followed by many modern scholars, maintained (and maintain) that neither the Mishna nor the *halakhoth* were committed to writing until the 6th century A.D. and that the Mishna was organized only orally by Rabbi Judah. On the other hand, many medieval rabbis, particularly of France and Germany, supported by many other modern scholars, were (and are) of the opinion that the Mishna was committed to writing by Judah. It can be deduced from internal evidence not only that the Mishna was written by Judah but that many *halakhoth* had been put in writing long before his time. The injunction against the writing of *torah shebe-al pe* (the unwritten law) refers only to the customs and the oral laws that had not yet been made statutory.

**Great Tannaim.**—Among the *tannaim* responsible for the shaping of the *halakhoth*, two disciples of Rabban Johanan ben Zakkai deserve particular mention: Rabbi Eliezer and Rabbi Joshua. Another sage was Rabban Gamaliel, the grandfather of Rabbi Judah ha-Nasi, the successor of Johanan ben Zakkai as head of the academy of Jabneh and chiefly responsible for the organization of the *halakhoth*. Rabbi Akiba by his great intellect and acumen had great influence in the shaping of the *halakhoth*. He introduced new methods of interpretation of the Bible for the purpose of enacting new laws. He laid the groundwork for the compilation of the Mishna that was accomplished later by Judah. His dialectic methods are recognized in the halakhic discussions of his disciples, particularly those of Simon, Judah, Jose and Meir. The last had the keenest legal mind. To this group must be added Rabbi Simon ben Gamaliel, the father of Judah ha-Nasi, who headed the academy at Usha. These are only a few of the *tannaim* who flourished after the destruction of the Second Temple. The tannaitic period ended with the compilation of the Mishna.

## THE TANNAITIC LITERATURE

**Midrash Mikra.**—There are other collections of laws, the works of the sages who maintained that the *halakhoth* should be arranged according to the sequence of the pentateuchal passages. They are: (1) *Sifra* ("the book" par excellence), in which the *halakhoth* are arranged in the order of the passages in the book of Leviticus; and (2) *Sifre* ("the books"), in which the *halakhoth* are arranged in the order of the passages in the books of Exodus, Numbers and Deuteronomy. These collections are called *Midrash Mikra*. (See also *MIDRASH*.)

**Tosefta and Baraitoth.**—Rabbi Judah collected *halakhoth* that he felt should be recorded in the Mishna as a way of life for the Jews. He did not include those which at that time were out of date due to social and religious changes that had occurred in the life of the Jews. For example, the laws of impurity, held by the sages to be inapplicable to the pagans, had become obsolete after the destruction of the Second Temple, since pagans were now considered human beings like the Jews and the laws of impurity became applicable to them; likewise, the law that a woman can be among the seven called to the Torah was omitted, since at this time women were already segregated in the synagogues. Rabbi

Judah's disciple Rabbi Hiyya bar Abba made a collection, called *Tosefta*, of those *halakhoth* that were not recorded in the Mishna. The sequence and the arrangement of the orders of the tractates in the *Tosefta* are similar to those in the Mishna; three tractates—*Aboth*, *Middoth* and *Tammid*—were omitted since they did not contain *halakhoth*.

There are notable differences between the Mishna and the *Tosefta*. In the Mishna eschatological ideas are not recorded and there are no references to reward for the righteous and punishment for the wicked after death. The *Tosefta*, on the other hand, deals with these speculations, and it states that wicked Jews and wicked pagans will be judged in Gehenna for 12 months as a kind of purgatory. However the Jewish apostates and informers would never be released from punishment. Righteous pagans would share a portion in the future world, and thus were placed in the same category as Jews. None of this, not even the word Gehenna, is found in the Mishna.

During the second commonwealth the Pharisees were inimical toward the apocalyptists, who were occupied with esoteric doctrines and metaphysical ideas and believed in a supernatural Messiah and a physical resurrection. The apocalyptists became influential after the conquest of Jerusalem by the Romans; some accepted Christianity while others infiltrated the ranks of the Jewish people. The *tannaim*, heirs of the Pharisees, continued their opposition, which is revealed in a story related in the *Tosefta*: Four men—Simon ben Azzai, Simon ben Zoma, Elisha ben Abuya and Rabbi Akiba—went into *pardes* ("paradise") and steeped themselves in mystic and esoteric philosophy. Only Akiba emerged without impairment to his faith or detriment to his intellect. Simon ben Azzai met with an untimely death, Simon ben Zoma became demented, and Elisha ben Abuya turned apostate.

The opposition of the *tannaim* toward apocalyptic doctrines was unsuccessful; indeed some of the *tannaim* themselves resorted to such speculations. Their strictures against superstition did not deter some *amoraim* from adopting these beliefs. Under the stress of personal misfortune and national calamity, people tend to seek solace in superstition and mysticism, and such has been the inclination of many Jews throughout the ages. Medieval Cabala (*q.v.*) was an outgrowth of apocalypticism, and many rabbis of the middle ages regarded Cabala as a menace to true Judaism, as their predecessors, the *tannaim*, had regarded apocalypticism. (See also APOCALYPTIC LITERATURE.)

A story in the *Tosefta* illustrates the endeavours of the followers of Jesus to convert the Jews to belief in him as the true Messiah, and also the disposition of the *tannaim* toward the Jewish Christians. It concerns a nephew of Rabbi Ishmael, Eliezer, who was bitten by a serpent. A certain Jacob sought to heal him in the name of Jesus, son of Panthera. Rabbi Ishmael forbade Eliezer to accept the ministrations of Jacob, and though Eliezer died, yet Rabbi Ishmael exulted, because his nephew had not succumbed to the Christian faith. The story led the 3rd-century Christian writer Origen, in his treatise against the pagan Celsus, to accuse the Jews of spreading false tales regarding the genealogy of Jesus by maintaining that he was the son of Panthera.

A number of additional *halakhoth* not included in the *Tosefta* but found in the Talmud are laws of the tannaitic period called *Baraitoth* (sing. *Baraita*; from a word meaning "outside," thus *halakhoth* outside the Mishna). The *Tosefta* and the *Baraitoth*, since they contain *halakhoth* that were already obsolete at the time of compilation of the Mishna, as well as other *halakhoth* that arose afterward, are more important than the Mishna itself for the history of the religious and social life of the Jews. The use of Roman legal terms in the *Tosefta* and *Baraitoth* shows the influence of Roman law on the tannaitic *halakhoth*.

Both the *Tosefta* and the *Baraitoth* differ in some respects from the Mishna. The latter, since it is a code, presents the laws in a legal form. The others are more informal, and in the *Tosefta* some laws are illustrated by parables. For example, a law which states that the owner of a field must not throw stones from the field onto public property is illustrated in the *Tosefta* by a story that stresses the moral. Once a proprietor in clearing a field threw the stones onto the public road. A pious man, observing this, told

the owner that he was really throwing stones onto his own property. Subsequently the owner, for economic reasons, was compelled to sell his field. Walking on the road where he had thrown the stones he stumbled on them and was injured.

## THE TALMUDS

The Mishna attained canonical authority soon after its completion. The sages and teachers who expounded it were called *amoraim*, and the work that resulted from their endeavours was the Gemara, known as the Talmud. The Gemara constitutes both a commentary on and an interpretation of the Mishna. There are two Gemaras—the Palestinian (*Talmud Yerushalmi*), written in Western Aramaic and replete with many Greek and Latin terms and expressions; and the Babylonian (*Talmud Babil*), written in the Eastern Aramaic dialect and sprinkled with Persian words. The Babylonian Talmud or Gemara is often called the Talmud.

**Contents.**—The Palestinian Gemara consists of 39 tractates: the entire orders of *Zeraim*, *Moed*, *Nashim* and *Nezikin* (with the exception of *Eduioth* and *Aboth*); and a section of the tractate *Niddah* of the order *Taharoth*. It contains none of the tractates of the order *Kodashim*.

The Babylonian Gemara consists of 37 tractates: one tractate, *Berakhoth*, of the order *Zeraim*; all of the order *Moed* except the tractate *Shekalim*; all of the order *Nashim*; all of *Nezikin* except *Eduioth* and *Aboth*; all of *Kodashim* except the tractates *Middoth* and *Kinnim*; none of the order *Taharoth* except *Niddah*.

The reason for the omissions is not known; perhaps they were lost. Although the Palestinian Talmud contains more tractates than the Babylonian, the latter is much fuller and larger.

**Talmudic Academies.**—The disciples of Judah ha-Nasi took up the study of the Mishna after his death. Tiberias became the centre of Jewish learning, but there were other *yeshivoth*, or academies, in Caesarea and Acco. The talmudic academies in Palestine soon fell into decay because of political and economic conditions. The Palestinian Jews at first were under the yoke of the Roman despotism. Later, when Christianity became the dominant religion of Rome, their condition worsened. They were not even allowed to communicate with their coreligionists in Babylonia and were compelled to employ a code to notify them of the intercalations of the year. By the end of the 4th century all of the academies in Palestine had ceased to exist and the compilation of the Palestinian Talmud came to an abrupt end.

Abba Arika, known as Rab, and Mar Samuel, disciples of Judah ha-Nasi, returned to Babylonia, their native land, after the death of their master, and Mar Samuel became the head of the *yeshiva* in Nehardea on the Euphrates. After that city was sacked by the Palmyrians a *yeshiva* was organized at Sura, headed by Rab (A.D. 219). Rab Judah ben Ezekiel, a disciple of Samuel, in mid-3rd century organized the great *yeshiva* in Pumbeditha which lasted more than seven centuries. These two *yeshivoth* became the leading centres of Jewish learning. The *yeshiva* of Pumbeditha was noted for the keen dialectics employed in the halakhic discussions, particularly prominent in which were Judah ben Ezekiel, Rabbah bar Nahmani and his nephew Abaye and his colleague Rabba. Their discourse at times soared into the realm of the incomprehensible.

In the *yeshivoth* the studies were designed for those persons, called *haberim*, who devoted their lives to research in the *halakhoth*. Sessions were also organized, however, to disseminate knowledge among laymen. There was a maxim among the *tannaim*, adhered to by the *amoraim*, that knowledge is superior to observance. These sessions were held in the spring in the month of Adar (March) and in the autumn in Elul (September), and the laity came to the *yeshivoth* and participated in talmudic discussions.

**Authors.**—All the *amoraim* contributed to the Talmuds, but the chief architect of the Palestinian Talmud (compilation of which ceased late in the 4th century) was Johanan bar Napakha, while the Babylonian Talmud was chiefly compiled by Rabbi Ashi (*q.v.*), the head of Sura academy in the early part of the 5th century A.D. It was completed by Rabina c. 499.

The *saboraim* ("those who reflect"), who flourished in the 6th

and the first part of the 7th century, explained the terminology and interpreted many passages. They also established rules to help in the understanding of the Talmud. Their interpretations and explanations became a part of the work. While some of their interpretations help in the understanding of intricate passages, others lead to confusion. It is difficult to know which passages came from the *amoraim* and which were interpolated by the *saboraim*, since no early manuscripts exist. The work of the *saboraim* on the Talmud was later carried on by the *geonim* (see GAON).

The Babylonian Talmud became the standard text of Jewish law and religion. It was considered divine. The *halakhoth* in the Talmud were authoritative; no rabbi could differ from them, he could only interpret. However, the *geonim* conceded that *haggada* was not authoritative.

**Character of the Talmud.**—The Talmud consists of *halakha* and *haggada* (Aramaic *agada*, "legend" or "narrative"), the former being far more numerous. The *amoraim* used the same method in their interpretation of the Mishna as the *tannaim* had in their interpretation of the Holy Scriptures. They employed exegetical principles in elucidating the *halakhoth* and expressions in the Mishna. Where there was tautology of words or expressions, the *amoraim* used them as basis for the deduction of new *halakhoth*. When there was a clash between two tannaitic principles, the *amoraim*, in their endeavour to harmonize conflicting opinions, introduced a new law.

**Halakhoth.**—The *halakhoth* of the Babylonian Talmud are the production of sages who lived in the Diaspora. This is reflected in the many laws that had to be adjusted to the life of Jews who no longer had their own state and government. Mar Samuel in 219 introduced a law that was far reaching in the life of the Jews throughout the ages—that the civil laws of the country were binding on the Jews. Many *halakhoth* reveal the influence of the laws of the country in which the Jews lived: the Palestinian Talmud reveals a marked influence of the Roman law, whereas in the Babylonian Talmud there is evidence of the effect of Parthian customs. On the other hand, many *halakhoth* in both Talmuds are academic, showing no reflection of the prevailing laws nor of the life of the Jews of the time.

Some *halakhoth*, particularly those of an academic nature, are characterized by dialectics and sometimes by quibbling and hair-splitting. Only a few *amoraim* indulged in this sort of discussion, however; the Palestinian *amoraim* protested against it, and the majority of Babylonian *amoraim* also condemned it.

**Haggadoth.**—A considerable part of the Talmuds consists of *haggadoth* of varying types. Those whose purpose is biblical exegesis are homiletical and explain the Scriptures allegorically. Others are stories, legends and proverbs whose purpose is to convey a moral message. Some are theological, dealing with rewards and punishments in the future world, the messianic age and the resurrection. There are *haggadoth* dealing with mysticism, angelology, demonology, astrology, dreams and their interpretation. Others are political, describing in legendary form the lives of the Romans and the Persians. There are historical legends about the lives of biblical and postbiblical people and accounts of the sufferings endured by the Jews. There are also aphorisms and maxims, humour and gaiety.

The aphorisms often reveal psychological insight and a humanitarian spirit: "He who gives charity in secret is greater than Moses himself." "The house that does not open to the poor shall open to the physician." "Let the honour of your neighbour be to you like your own." "There are three crowns: of the Torah, the priesthood, the kingship; but the crown of the good name is greater than all." "Whoever runs after greatness, greatness runs away from him; he who runs from greatness, greatness follows him." "No man is to be made responsible for words he utters in his grief." "The soldiers fight and the kings are the heroes." "When the thief has no opportunity for stealing, he considers himself an honest man." "One eats, another says grace." "The thief invokes God while he breaks into the house."

**Superstition.**—Superstition figures prominently in the Talmuds particularly the Babylonian. Even the sages who deplored superstition were forced by public pressure to permit the wearing of

amulets on the sabbath in order to avert the evil eye and protect the wearer from evil spirits. Dreams and their interpretation occupied the minds of men of the ancient world; references in the Bible to dreams and to those who had the wisdom to interpret them rightly are familiar. In the Talmud lengthy passages are devoted to dream interpretation, some sages believing that dreams are prophetic, others that they are of no significance. Belief in omens and astrology was widespread even among intellectuals, hence astrological speculations are found in the Talmud. Most *tannaim* and *amoraim*, however, condemned these beliefs as idolatrous. Other *amoraim*, regarded by the people as holy men capable of performing miracles, indulged in speculations in theosophy and mysticism. But mysticism was not integral to normative Judaism, and halakhists opposed it.

**Science.**—The sages of the Talmud were learned in geometry, astronomy and medicine, sciences that were of great importance in halakhic decisions: geometry in connection with the rules and matters of agriculture, astronomy in relation to the intercalation of the months and years, medicine in the matter of the laws of ritual purity and impurity.

**Other Religions.**—The attitude of the sages toward other religions was antagonistic. As monotheists, who maintained that God is universal—the God of the entire human race—they opposed idol worship. They forbade the partaking of bread and wine with pagans, since the pagans used wine in their libations to the idols and bread in their worship, and to the Jews the table was sacred. Their attitude toward non-Jews was analogous to that of the Hellenes toward non-Hellenes, but it was based not on belief in racial superiority but on religion, and the sages welcomed proselytes—one who accepted Judaism was regarded more highly than a native Jew (see PROSELYTE). No laws were directed against gentile Christians, but certain strictures were passed upon Jewish Christians, who were regarded as heretics and apostates and suspected besides of being informers to the Romans. The rabbis, since they considered the Jewish Christians to be the destroyers of Judaism, showed great animosity toward them. When Christianity became a gentile religion their animosity disappeared: Christianity was a different religion, one that brought the idea of the universality of God to the pagans. Passages about Jesus in the Babylonian Talmud show that the Babylonian *amoraim* had no conception of the historical Jesus and of the time when he lived; all they knew about him was compounded from hearsay. It is worthy of note that there is no mention of Christianity and its founders in the Palestinian Talmud. Either the rabbis were indifferent or they were afraid to speak candidly because at that time Christianity was the dominant religion of Rome; or, perhaps, passages concerning Jesus and Christianity have been deleted.

## CRITICISM AND COMMENTARY

**Attacks.**—The first attack against the Mishna was made by the Church Fathers, who construed it as a menace to Christianity. The Fathers interpreted biblical passages so as to support the truth of Christianity, while the *tannaim* employed the same passages to support their own tradition. There is no word in the Mishna about the founders of Christianity, hence the Church Fathers inferred that it denied the truth of Christianity. As a new, young religion, Christianity had to fight for its very existence, and the Mishna was regarded as a threat. Unable to read the Talmud in the original, church authorities relied occasionally on tendentious translations made by Jewish apostates. In the 16th century the emperor Justin prohibited the reading of the Mishna.

Throughout the middle ages the Talmud continued to be attacked by Christians. A public disputation was held in Paris in the 13th century, and later there were disputations elsewhere. In the early part of the 16th century the apostate Johann Pfefferkorn wrote a bitter attack against the Talmud, on the basis of which the emperor Maximilian ordered it to be burned; the Christian humanist Johann Reuchlin (*q.v.*), however, defended the work against the accusations of the apostate, and the emperor rescinded his decree. The Talmud was, however, in fact frequently burned, and it is for this reason that so few early manuscripts survive. As late as the mid-18th century copies were burned in Poland, though

after the middle ages the work was subject more to censorship than to destruction.

During the middle ages the Jewish Karaites, motivated chiefly by resentment against the exilarch and the *geonim*, attacked the Talmud as a compilation of casuistic arguments, myths and superstitions, denying also the divine origin of its laws (see KARAISM). During the period of decline in Jewish intellectual life during the late middle ages and Renaissance the Talmud came to occupy an exaggeratedly exalted position, being studied even to the exclusion of the Bible. The enlightenment that came in the 18th century, particularly as exemplified by Moses Mendelssohn, brought a reaction. Liberal Jews in modern days do not regard the Talmud as divinely inspired but as a portion of the sacred tradition and a monumental source of Jewish history. In modern *yeshivoth* it is still the major, sometimes the sole subject of study.

**Commentaries.**—The best commentary on the Babylonian Talmud was written by Rashi (*q.v.*), but there are numerous other commentaries and novellae compiled by rabbis throughout the ages. Among translations may be mentioned Herbert Danby's of the Mishna and the Soncino translation of the Talmud. However they are not perfect, and a critical edition of the Talmud is yet to be made. Many passages are corrupt, and the work was never well edited. While its language is chiefly Aramaic, it is a mixture of many dialects. It may be compared to a primeval, dense forest in which a person will lose his way without a skilful guide. (S. Z.)

**Source Criticism.**—The Talmud is not immune to the manifold problems besetting all ancient texts, particularly those that were orally transmitted (see TEXTUAL CRITICISM). Indeed textual criticism of the Talmud is as old as the Talmud itself, though not until modern times did it become a separate scholarly concern.

The rabbis of antiquity often emended rabbinic texts, inserting readings (*e.g.*, *Talmud Babli*, *Berakhoth* 13b), substituting one reading for another (*e.g.*, *T.B.*, *Yebamoth* 41a) or rejecting outright Baraitoth (*e.g.*, *T. B.*, *Gittin* 73a) or statements of *amoraim* (*e.g.*, *T.B.*, *Pesahim* 11a) because they considered them to be hopelessly corrupt. Nor did later scholars of the Talmud desist from correcting one text on the basis of another that seemed to them to be more reliable. Sometimes they even emended a text without support from another text. Talmudic text criticism, unlike biblical criticism, which had to contend with a long and revered tradition, was always acceptable even to the religiously conservative scholar; it is more often than not the modern liberal scholar who protests against excessive emendation (even when sanctioned by tradition) on the ground that it is inconsonant with what is known about the natural development of texts in general.

That is not to say that the traditional attitude set no limits to talmudic textual criticism. A distinction was always drawn between a reading substantiated by internal evidence in the Talmud itself and a reading not so substantiated. The former was always taken to be valid, while the latter was acknowledged to have been open to the possibility of scribal error. With the advent of modern scholarship, this distinction ceased to be compelling.

Source criticism seeks to differentiate between the original statements as they were enunciated by their authors and the forms they took as a consequence of being orally transmitted; that is, between the sources and their later traditions. It is not to be confused with the kind of analysis—frequently carried out by the rabbis of the Talmud—which merely traces the historical sources of a given passage without judging whether or not the passage faithfully reflects these sources. Source criticism claims that the transmission of the Talmud was not, and perhaps could not have been, verbatim, and that the text became altered in transmission, with the result that many statements in the Talmud have not come down in their original form. Instead, what survives is the form assumed in the last phase of transmissional development. While such a study is pertinent to most ancient texts, it is particularly relevant to the Talmud, which primarily consists of quotations and their interpretations.

Traces of source criticism can be found in geonic literature, but credit for pioneering work belongs to the Galician-born scholar H. M. Pineles (1805–70), who in his *Darka Shel Torah* (1863) for

the first time offered a systematic critical approach to the study of talmudic sources. J. N. Epstein (1879–1950), professor of Talmud at the Hebrew University, Jerusalem, made a major contribution to source criticism through his comprehensive *Introduction to the Mishna* (1948) and *Introduction to Tannaitic Literature* (1957).

(S. Z.)

**TAM, JACOB BEN MEIR** (1100–1171), known also as RABBENU TAM, a grandson of Rashi (*q.v.*) and brother of Rashbam, was the most famous of the French glossators (*Tosafists*) on the text of the Talmud. He was born at Ramerupt, in northern France, in 1100. In 1147 he was attacked in his home and injured by a disorderly band who had attached themselves to the crusaders. He escaped to neighbouring Troyes, where about 1160 was held the first of the Jewish synods for which the Rhineland became celebrated. At this meeting it was laid down that disputes between Jew and Jew were not to be carried to a Christian court but were to be settled by fraternal arbitration. New conditions of life had arisen because of the closer terms on which Jews and Christians lived, and Jacob Tam was foremost in settling the terms which were to govern the relations, from the Jewish side. His practical ordinances (*takkanoth*), connected with marriage and divorce, trade, and proselytism, as well as with synagogue ritual, bear the stamp of enlightened independence within the limits of authoritative tradition and law. Of his legal work the most important was collected in his *Sefer ha-Yashar*. He was also a poet of considerable merit, composing both secular and liturgical poetry, and a grammarian. Rabbenu Tam died at Troyes June 9, 1171.

See H. Gross, *Gallia Judaica*, p. 230 ff. (1897); M. Schloessinger in *The Jewish Encyclopedia*, vol. vii, pp. 36–39. (I. A.)

**TAMALE**, the capital town of the Northern Region of Ghana, is 437 mi. (703 km.) NNE from Takoradi, Ghana's chief seaport on the Gulf of Guinea, and 406 mi. N from Accra, the capital of Ghana. Tamale lies 600 ft. (183 m.) above sea level in a plain between the White Volta to the west and the tributaries Taha Kulibong and Pagazaa to the east. Its nearest point to the White Volta is at Dalong, 22 mi. away. The climate is hot and wet. The town covers approximately 4.5 sq.mi. Pop. (1960) 40,443.

The official residence of the chief regional officer is in Tamale, and many government departments have their offices there. In addition to the regional education office, government educational establishments include a teachers' training college and a centre for instructing artisans in various trades. The vernacular literature bureau provides newspapers and literature for mass literacy campaigns in the region; personnel for these campaigns and for work in community development are trained at the rural training centre.

Tamale is an agricultural trading centre where the main occupation is farming and crop cultivation in particular. Yams, maize, guinea corn, millet, rice, peanuts, and cow peas are grown, and a small quantity of cotton is produced. There is some cotton milling, and the shea nut is processed. Commodities exported, but almost exclusively within Ghana, are rice, guinea corn, peanuts, cow peas, and shea butter. The principal imports are cotton prints, farm tools, hardware, salt, and kola nuts.

The main road, which runs northward from the coast roughly through the centre of the country, passes through Tamale; other roads enter it from the east and west. (J. S. K.M.)

**TAMAR**, a river of England, rises within 4 mi. (6.4 km.) of the Bristol Channel and flows south across the southwestern peninsula to the English Channel at Plymouth. With its tributaries it drains 599 sq.mi. (1,551 sq.km.). Over the greater part of its length of 61 mi. (98 km.) it forms the boundary between Corn-

wall and Devon. For 30 mi. from its source at 720 ft. (219 m.), its valley (like those of its headstreams Deer and Claw and of its tributaries Ottery, Carey, Kensey, Thrushel, and Lyd which meet it near Launceston) is shallowly but clearly cut into low plateau lands on Carboniferous rocks. Farther downstream where it passes onto Devonian rocks and crosses an east-west, granite-defended ridge of higher land between Dartmoor and Bodmin Moor it exhibits impressive, incised meanders with steep wooded side slopes rising abruptly from a narrow, almost flat, valley floor. The meandering valley continues beyond tidehead (1 mi. below Gunnislake, formerly its lowest bridging point) through an important fruit and flower growing district. Its estuary, 19 mi. long to Plymouth Sound, up to 1 mi. wide and discontinuously fringed with salt marshes, is crossed by the railway at Saltash (I. K. Brunel's Royal Albert Bridge); like those of its lower tributaries, Tavy, Lynher, and Tiddy, the Tamar Estuary is a barrier to road traffic, carried by ferry at Torpoint and the Tamar road bridge upstream of Brunel's bridge. The sheltered deepwater estuary (—80 ft. Ordnance Datum at Saltash) is the site of Plymouth Naval Base and Devonport Dockyard. (R. S. W.)

**TAMARIND**, a tropical leguminous tree (*Tamarindus indica*) and its pod fruit. The tree, widely distributed in tropical countries, is generally considered to be native to eastern tropical Africa, from Ethiopia southward to the Zambezi river. The name (meaning in Arabic "Indian date") shows that it entered medieval commerce from India, where it is used not only for its pulp but also for its seeds, which are astringent; its leaves, which furnish a yellow or a red dye; and its timber. The tree attains a height of 70 to 80 ft. and bears elegant pinnate foliage and purplish or orange veined flowers arranged in terminal clusters.

The pods are filled with an acid juicy pulp containing sugar and various acids, such as citric and tartaric, in combination with potash. The acid pulp is used as a laxative, the pods being largely exported from the West Indies and Indonesia.

**TAMARISK**, a small group of shrubs or low trees of the genus *Tamarix*, constituting the family Tamaricaceae. The species of tamarisk and of an allied genus *Myricaria* (false tamarisk) grow in salt deserts, by the seashore or in other more or less sterile localities in warm-temperate, subtropical and tropical regions of the eastern hemisphere. Their long slender branches bear very numerous small appressed leaves, in which the transpiring surface is reduced to a minimum. The numerous small pinkish flowers, borne in long clusters at the ends of the branches or from the trunk, give the shrubs a feathery appearance. Each has four to five free sepals, and as many petals springing with the four to ten stamens from a fleshy disk. In *Tamarix* the stamens are free, while in *Myricaria* they are united into one parcel. The fruit is capsular and contains numerous seeds, each usually with a long tuft of hairs at one end. The value of these shrubs or trees lies in their ability to withstand the effects of drought and a saline soil; they grow where little else can flourish. On this account the common tamarisk (*T. gallica*) the salt cedar, or French tamarisk, is planted on seacoasts and affords shelter where none other could be provided. In Asia Minor *T. gallica* is one of the manna producers (see MANNA). The Athel tamarisk (*T. aphylla*), native to western Asia, has been introduced as a windbreak in desert areas in southern California. Several species are cultivated as ornamentals.

**TAMATAVE** (TOAMASINA), the chief port of Malagasy Republic (Madagascar) and capital of Tamatave Province, lies on the east (Indian Ocean) coast, 135 mi. (217 km.) NE of Antananarivo (Tananarive). Pop. (1963 est.) 50,500. It stretches along a sandy beach between two points prolonged by coral reefs. The southern coral reef forms the harbour, which is entered by two openings. Sandy or rocky bars have been cut to join the town with the Canal des Pangalanes, which links together the extensive lagoons of the east coast. The town was rebuilt and extended on modern lines after its destruction by hurricane in 1927. The remains of the old town are at the southern point. The modern town, to its north, centres around the treelined Avenue Poincaré. New construction includes the town hall, a sports stadium, a swimming pool, schools, and cinemas. The botanical garden of Ivoloia is 6 mi. (10 km.) N of the town.

Tamatave is the chief commercial centre of the republic and handles about 50% of its foreign trade. It exports the products of the east coast (coffee, vanilla, pepper, cloves, and graphite) and imports machinery, textiles, and foodstuffs. There are meat-preserving and canning factories; other industries are sugar refining and rum distilling. The town is the terminus of the railway from Tananarive (capital of the republic) and has an airfield with flights to the capital and to east coast towns.

Tamatave was first visited in the 17th century by the Portuguese, who founded a trade centre there. In 1811 it was occupied by the English and given to the French in 1814. In 1822 it was besieged by the Merina (Hova) kingdom and French occupation was finally consolidated in 1895.

**TAMATAVE PROVINCE** (area 27,765 sq.mi. [71,911 sq.km.]; pop. [1963 est.] 954,617) comprises the central part of the fertile east coast plain, which rises to dissected highlands in the west. It is drained in the south by the Mangoro River and in the north contains Lake Alaotra. The island of Sainte-Marie, just off the east coast, is part of Tamatave Province. (J. Ar.)

**TAMAULIPAS** a northeastern state of Mexico. Area 30,822 sq.mi. (79,829 sq.km.). Pop. (1960) 1,024,182. The central and southern parts of the state are mountainous, but there are extensive fertile plains in the north. The coastal zone is sandy, much broken by lagoons, and sparsely inhabited. The foothills region back of this is usually well-wooded and fertile, and the low alluvial river valleys penetrate deeply into the Sierras. The climate is hot and humid on the coast, but is pleasant on the more elevated lands of the interior. Rainfall is abundant, especially on the mountain slopes of the south. Agriculture is the principal industry. Sugar, cereals, tobacco, cotton, and coffee are produced, and fruit is also grown successfully. Large tracts of farm land are irrigated. Stock raising receives some attention, and hides and cattle are exported. The preparation of istle fibre for export is becoming an important industry. Copper is mined and extensive deposits of petroleum and asphalt are being exploited. The state has excellent rail, air, and highway connections.

The capital of Tamaulipas is Ciudad Victoria (pop. [1960] 50,797), on the Monterrey and Tampico Railway, about 120 mi. (193 km.) from Tampico. The city was founded in 1750, and is on one of the trunk highways extending to Mexico City from the Texas border. Among other towns may be mentioned: Tampico (q.v.; 122,535), Ciudad Madero (53,628), Nuevo Laredo (92,627), Matamoros (q.v.; 92,327), and Reynosa (74,140), the latter three being on the U.S. border. Reynosa is the site of a large gas plant which has a daily production potential of 300,000,000 cu.ft. (8,500,000 cu.m.) of natural gas.

In 1957 a pipeline was opened to carry huge quantities of this gas into the United States. Many miles of new paved highways were completed in the state, bringing all of its towns within easy reach of each other. (J. A. Cw.)

**TAMAYO Y BAUS, MANUEL** (1829–1898), Spanish dramatist, who, with Adelardo López de Ayala, dominated the Spanish stage from 1850 to 1870. He was born in Madrid Sept. 15, 1829, and died there June 20, 1898. He came of a theatrical family and was an accomplished man of the theatre. *Virginia* (1853) is an essay in classical tragedy. *La ricahembra* (1854) and *Locura de amor* (1855) are romantic historical dramas. Several "thesis" plays denounce, from a conventional conservative standpoint, moral evils in contemporary society: materialism (*Lo positivo*, 1862), dueling (*Lances de honor*, 1863), and tolerance of corruption in high places (*Los hombres de bien*, 1870). International fame came with *Un drama nuevo* (1867; English translation, *A New Drama*, 1915), a skilful and at times moving tragedy set in the Shakespearean theatre. His abandonment of verse reflects the movement away from Romantic extravagances toward greater naturalness, and his comfortable morality found ready acceptance with his comfortable audiences. (H. B. Hl.)

**TAMBOV**, an oblast of the Russian Soviet Federated Socialist Republic, U.S.S.R., was formed in 1937. Area, 13,243 sq.mi. Pop. (1959) 1,549,001. It occupies the low, level Oka-Don plain on the watershed between the two river basins. Only in the east does the land rise slightly toward the Volga uplands. Drainage is

north to the Oka by the Tsna and its tributaries and south to the Don by the Vorona and several smaller streams. The climate is continental, with a January average temperature of 11° C. (13° F.) and a July average of 20° C. (68° F.). The annual rainfall is 19 in., with a summer maximum. The natural vegetation is forest steppe, much of which has been cleared for agriculture since the soils are rich chernozems. There are large areas of pine forest on sandy soils only along the right bank of the Tsna and along the Vorona.

In 1959 only a small proportion, 408,210 or 26% of the population, was urban. These people live in seven towns and five urban districts, of which the largest are Tambov (172,171) and Michurinsk (80,653). Most of the industry is concentrated in these two towns, the other centres being engaged in processing local farm produce.

Agriculturally the *oblast* is important, with grains occupying first place. Winter rye, spring wheat, maize (corn), oats and millet are grown. Sunflowers are the chief industrial crop, but there is some sugar beet, hemp and tobacco. Potatoes, melons and other vegetables are widespread. Beef and dairy cattle and poultry are the main livestock.

Other principal towns are Morshansk, founded in the 17th century on the Tsna (manufactures of glass, cloth and makhorka tobacco); and Kirsanov (founded 18th century) on the Tambov-Saratov railway (smelting works). (R. A. F.)

**TAMBOV**, a town and *oblast* administrative centre of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the left bank of the upper Tsna, on the Oka-Don plain, 260 mi. S.E. of Moscow. Pop. (1959) 172,171. It was founded in 1636 as a fortress on the Belgorod defensive line. In 1779 it became centre of a *guberniya* (pre-Revolutionary province). Development came slowly, chiefly in the late 19th century after the construction of the Moscow-Saratov railway through the town. Tambov's chief industry is engineering, chiefly the making of parts for vehicles and farm machinery, and the manufacture of electric motors and turbines, and machinery for the chemical and food industries. The last two are represented by the manufacture of synthetic rubber, dyes and paints and the processing of local agricultural produce. There are also rolling stock repair yards. Apart from the main line, there is a branch railway to Balashov and to Kamyshin on the Volga, and the Tsna is navigable downstream as far as Morshansk for pleasure launches and small barges.

In 1940 the southeastern part and adjacent suburb were constituted as the separate town of Kotovsk. Cultural institutions at Tambov include a pedagogic institute and a school of music. (R. A. F.)

**TAMERLANE**: see TIMUR.

**TAMIL**, peoples from south India who have perhaps the oldest cultivated Dravidian language and literature. Numbering about 32,000,000 in the 1960s, Tamil speakers (see DRAVIDIAN) inhabited chiefly Madras state and parts of Kerala, Mysore, Andhra Pradesh and northern Ceylon (*q.v.*). Emigrant Tamil may be found in Madagascar, Malaya, Burma, Indochina, Thailand, south and east Africa, the Fiji and Mauritius islands, and the West Indies. The term Tamil was in very ancient times applied to the language and peoples of a wider area of south India, including those now speaking Malayalam. The term is used also to designate the culture and literature of the people; it is a linguistic and geographical word and includes persons of varied social status and customs (see TAMIL LANGUAGE; TAMIL LITERATURE). The Tamil area in India is a centre of traditional Hinduism. The largest occupational group are cultivators, and although most are Hindu, there are Christian and Muslim Tamil. They are predominantly patrilineal with patrilineal residence; in the kinship system of the lower castes, however, matrilineal and affinal bonds are also found. Traditional marriage alliances are maintained between clanlike exogamous patrilineal subdivisions of endogamous castes and tribes. Among non-Brahmans divorce is common, as is remarriage and widow remarriage; Brahmins and some non-Brahmins disapprove of these and place greater emphasis on the lineage and on respect for elders in the extended family.

The Tamil have a long history of achievement; sea travel, city life and commerce seem to have developed early. Tamil trade with Greeks and Romans is verified by literary, linguistic and archaeological evidence. Their rich literature reaches to the early Christian era, and Tamil schools of personal religious devotion (*bhakti*) have been important in Hinduism (*q.v.*). South Indian classical music and the celebrated classical dance Bharata Natyam (*q.v.*) owe much to the Tamil who are masters and teachers of these arts.

Leach (ed.), *Aspects of Caste in South India* (1960); M. N. Srinivas, *Caste in Modern India* (1962); R. L. Hardgrave, Jr., "DMK and the Politics of Tamil Nationalism," *Pacific Affairs*, vol. 37 (1965).

(M. B. S.; R. RA.)

**TAMIL LANGUAGE**, one of the principal Dravidian languages (see DRAVIDIAN), spoken in South India and perhaps the only example of an ancient classical tongue which has survived as a spoken language for more than 2,500 years with its basic structure almost unchanged. The official language of Madras (*q.v.*), it is one of the 14 major languages recognized by the constitution of India (1949). At the 1961 census, Tamil was the mother tongue of 30,465,442 persons, 7.4% of the population of India. It is also spoken in the north of Ceylon and by many settlers in South and East Africa, Mauritius, Malaya and Fiji.

The Tamil script can be traced to Grantha and Vatteluttu epigraphical sources of the 3rd century A.D. onward (see TAMIL LITERATURE). That it had reached something akin to its present form by the 11th century may be seen from the inscription of Rājārāja Cola in the Great Temple in Thanjavur (Tanjore). Tamil script differs from others of South India mainly in excluding separate characters for the voiced velar, palatal, retroflex, dental and labial plosives, the voiced and voiceless aspirated plosives of these series, and the sibilants. However, the character of the palatal plosive *c* is realized as a dental or palatal sibilant in certain positions and is used to represent sibilants in loanwords. Also, Grantha characters are borrowed to represent the sibilants *s*, *sh*, the voiced plosive *j* and the voiced spirant *h*. Other plosives are represented by the corresponding voiceless unaspirated plosive.

Thus, the character for *h* represents also *kh*, *g* and *gh* in, for instance, Sanskrit loanwords. Moreover, the plosives are realized as voiced in certain positions according to fairly consistent rules, the principal being that a medial single plosive is realized as voiced, and a medial doubled plosive as voiceless with tense utterance. Tamil includes three consonants not found in the syllabaries of the Indo-Iranian languages of India and not now fully represented in other Dravidian languages: the trilled *r*, the alveolar nasal *ṇ* and the retroflex fricative *ḷ*.

Like other Dravidian languages, Tamil is regarded as agglutinative in formation. While its close affinity with other south Dravidian languages, especially Malayāḷam and Kanarese, is undisputed, the affiliations of the whole family have not been satisfactorily explained. The classical view, as stated by R. A. Caldwell, is that they are connected with the Scythian languages, but many of the similarities of structure and forms he cites may be accidental.

Tamil exhibits inflexional features also, wherein postpositional words are reduced to suffixes, sometimes monosyllabic. It agrees generally with other languages in broadly classifying words into verb roots, nouns and adjectives. In common with other languages of the same family, there is evidence, although vestigial, of a separate negative verbal conjugation and, in the sense of the Spanish *ser*, the verb for "to be" is unexpressed except in the negative. Case terminations are added to the plural noun-suffix and are unaffected by it, being identical with those used for the singular.

**TAMIL LITERATURE.** Tamil is perhaps the best-known of the Dravidian languages spoken in South India. Apart from Sanskrit, its literature is the oldest in India and, if epigraphical sources are included, may be said to commence in the 3rd century B.C. with some fragmentary cave graffiti found near Madurai. (See DRAVIDIAN; TAMIL; TAMIL LANGUAGE.)

**Period of the "Sangam".**—The earliest Tamil writings that may properly be termed literature are those of the *sangam*, or "literary academy." Tradition, much of it doubtless fanciful, tells of a *sangam* at Madurai which grew up during the middle ages, where a number of anthologies of secular court poetry were compiled—the Eight Anthologies, *Ēṭuttōkai*, and the Ten Songs, *Pattuppāṭṭu*. Possibly unique in early Indian literature, which is almost entirely religious, these poems are concerned with two main topics, love and the praise of kings and their deeds. Many, especially on the latter subject, display great freshness and vigour and are singularly free from the literary conceits of much of the other early and medieval literatures of India (see INDIAN LITERATURE).

Since they are secular, these poems are also free from the complex mythical allusions which are such an outstanding feature of most Indian art forms. *Sangam* poetry seems to be at least partly based on personal experience; in this respect it is curiously modern and unlike anything else to be found in India before the late 19th century. From references to trade with the west and other internal evidence, it seems likely that these poems belong to the first four centuries A.D., when trade with Rome via the middle east was still active.

*Paripāṭal*, possibly the last of these anthologies, marks the transition to the next, more formal, stereotyped style, for it includes both religious poetry, abounding in the usual allusions, and, still in the older vein, some fine descriptive poetry, which depicts the course of the Vaigai river, on which Madurai stands.

**Sixth to Ninth Centuries.**—To the 6th century and after belongs that great collection of Śaiva religious poetry (see HINDUISM: Gods) called, collectively, *Tirumurai*. Among its 12 books are the *Tevāram*, consisting of the hymns of Appar (Tirunāvukkaracu), Tiruñānacampantar and Cuntarar; and Māṇikkavācakar's mystical poem *Tiruvācakam* (Eng. trans. by G. U. Pope). The 12th book, the 12th-century *Pēriyapurāṇam* of Cekkīlār, describes the lives of the 63 Śaiva *nāyanmār* ("saints").

Of possibly the same period as the first few books of *Tirumurai* are the "Eighteen Minor Works." Largely didactic, these include the well-known collections of aphorisms, *Tirukkural*, by Tiruvalluvar. This work is highly esteemed by the Tamilians, and there are several translations. Another similar work is the *Nālaṭiyār*.

Similar in subject matter to the *Tevāram*, though somewhat later in date, are the hymns of the *Nālaṭirappirapantam*, which differ only in that they praise the god Viṣṇu (Vishnu). They are the work of the 12 Vaiṣṇava devotees or Ālvārs, the most interesting of whom is, perhaps, Aṇṭāl, the girl-foundling reared by a Vaiṣṇava priest.

The epics *Cilappatikāram* and *Maṇimēkalai*, written by Ilanko-vaṭikaḷ and Cātṭanār respectively, may probably be assigned to the 6th or 7th century. The former tells of a merchant Kovalan who neglects his wife Kaṇṇaki, lavishing his wealth on a courtesan called Mātavi. Later, impoverished as a result of his excesses, Kovalan and his faithful wife travel to Madurai, where they try to start a new life, selling Kaṇṇaki's golden anklets to raise capital. Wrongfully accused of stealing these from the queen, Kovalan is executed. Kaṇṇaki fully exonerates her husband before the king, who dies of remorse, and she herself, in her frenzied grief, tears off her left breast and curses the city, which is consumed by fire. She then makes her way to another royal city, Vañci, where she dies, and is received into heaven to join Kovalan.

Though a Buddhist work, *Maṇimēkalai* is a sequel to the

*Cilappatikāram* in that its heroine, Maṇimēkalai, is the daughter of Mātavi by Kovalan. Mother and daughter have both become Buddhist nuns; the prince, Uṭayakumāraṇ, falls in love with Maṇimēkalai, and the pair finally realize that they were married in a former birth.

**Ninth to Twelfth Centuries.**—Three famous Tamil poets, Kampan, Oṭṭakkūṭṭan and Pukaḷentī, belong to this period, but it is not possible to date them with any exactness. Kampan was author of the principal Tamil version of the *Rāmāyaṇa*. In his version, given a South Indian setting, Rāma is regarded not only as hero of the story but as a god and incarnation of Viṣṇu—as is usually the case with vernacular *Rāmāyaṇas* in India. The work, begun by Kampan, was completed by Oṭṭakkūṭṭan.

Cayaṅkōṇṭān's *Kalīṅkattupparani*, an 11th-century work, describes the victorious war waged by the Coḷa king against the neighbouring ruler of Kāliṅga. It opens with a grandiose genealogy of the Tamil king, and closes with a gruesome description of the carnage of battle and of the corpses being devoured by she-devils.

A number of commentators and grammarians belong to this period. Among the former may be mentioned Aṭiyārkkunallār, who wrote the commentary on *Cilappatikāram*, and Naccinārkiṇiyar, who, in addition to commentaries on *Pattuppāṭṭu* and some of the *Ēṭuttōkai*, wrote one on part of the early "grammar" *Tōlkāppiyam*.

**Twelfth to Sixteenth Centuries.**—Tamil literature became increasingly concerned with philosophical treatises and with creating *Purāṇas* (anthologies of religious legends), which, in this case, describe the myths about the various shrines of South India. Most important among the former are perhaps those (for example Mēykaṇṭatevar's *Civañāṇapotam*) which expound Śaiva-siddhānta philosophy.

Among the *Purāṇas* mention may be made of the *Tiruvilaiyār-purāṇam* of Parañcotimuniyar, which recounts the 64 divine sports of the god Śiva (Shiva) in connection with the founding of the great temple at Madurai.

**European Influence and the Modern Period.**—After the collapse of the Vijayanagar empire in 1565, South India was split into a number of petty states, but some of these, such as Thanjavur (Tanjore), continued to patronize writers. Missionaries from the west were also active in the Tamil area. The earliest of these, apart possibly from St. Francis Xavier (q.v.), were Roberto de Nobili in the 17th century and another Italian Jesuit, Joseph Beschi, born near Mantua in 1680. Both lived as Hindu ascetics and Beschi studied not only grammar but composition. He produced an epic, the *Tempāvāṇi*, which tells the story of St. Joseph and is based on an earlier model, *Civakucintāmaṇi*. In 1738 he produced a grammar of Tamil in Latin, probably the first to be written in a European language.

British Tamil studies were initiated by the manuscript collections of Col. Colin Mackenzie, who arrived in India in 1783. Later scholars of Tamil from the west included Robert Caldwell, whose *Comparative Grammar of the Dravidian . . . Languages* appeared in 1856; and the Rev. G. U. Pope who, besides writing a number of grammars, translated several Tamil works, including the *Tirukkural*.

In the 19th century, Tamil increasingly availed itself of western literary forms and ideas, and prose, hitherto reserved for inscriptions and commentaries, became accepted as a literary medium. The first novel was *Piratāpa Mutaliyār Carittiram*, by Vedanāyakan Pillai. The most famous poet of modern times is C. Subrahmanya Bharati (d. 1922). Perhaps his most lasting work is *Kaṇṇan Pāṭṭu*, a touching and lyrical cycle on the god Kṛṣṇa (see VISHNUISM). His work combines the best of the techniques of east and west. More recent is *Pāratidācan* whose poems about children and the family are especially attractive.

Much modern Tamil writing is devoted to regional politics and can hardly be said to be of permanent value; however, such writers as Aṇṇāṭṭurai and Karuṇāṇiti proved their worth in other work, for example, in the writing of filmscripts, and their contribution to Tamil literature may become more lasting. A number of excellent literary journals, such as the humorous weekly *Aṇṇaṭṭu*

*Vikatan* and the magazine *Kalki*, afforded South Indian writers a medium and helped to foster good writing.

**BIBLIOGRAPHY.**—Translations into English, other than those mentioned in the text, include *The Lay of the Anklet*, trans. by V. R. Ramachandra Dikshitar (1939); *The Story of King Nala and Princess Damayanti*, trans. by M. Langton (1950); *The Ayodhya Canto of the Ramayana*, from Kampan's version, trans. by C. Rajagopalachari for the United Nations Educational, Scientific and Cultural Organization (1961); V. Cronin, *A Pearl to India: the Life of Roberto de Nobili* (1959); W. C. Mackenzie, *Colonel Colin Mackenzie* (1953); V. R. Ramachandra Dikshitar, *Studies in Tamil Literature and History* (1930). (Jo. R. M.)

**TAMM, IGOR EVGENYEVICH** (1895– ) Russian physicist, who was awarded the 1958 Nobel Prize for Physics jointly with P. A. Cerenkov and I. M. Frank "for the discovery and interpretation of the Cerenkov effect." was born in Vladivostok on July 8, 1895. This effect, which was first described by Cerenkov in 1934, is concerned with the emission of light waves by electrons moving at very high speeds and is of great importance for the study of nuclear physics (see CERENKOV RADIATION).

Tamm, a professor at Moscow University, and his co-worker Frank provided a theoretical explanation of the Cerenkov effect in 1937. He became one of the best-known Soviet physicists and a member of the Academy of Sciences of the U.S.S.R.

In 1946 Tamm shared the Stalin Prize with Cerenkov and Frank for their joint work on electron radiation. He worked on the quantum theory of diffused light in solid bodies, on the photo-effect on metals, and on methods for the control of thermonuclear reactions. His technique of interpreting the interaction of elementary nuclear particles is known as the Tamm method. He appeared on U.S. television in May 1963, appealing for international disarmament based on increasing trust among nations.

See T. N. Levitan, *Laureates: Jewish Winners of the Nobel Prize* (1960). (W. J. Br.)

**TAMMANN, GUSTAV HEINRICH JOHANN APOLLON** (1861–1938), German physical chemist whose researches into the states and reactions of matter, especially of metals, made him one of the founders of metallurgy, was born at Yamburg (Kingisepp), near St. Petersburg (Leningrad), on May 28, 1861. He studied at the University of Dorpat (Tartu) in Estonia, and in 1892 became professor and director of the Chemical Institute there. In 1903 he went to the University of Göttingen in Germany as a professor of inorganic chemistry and was head of the Institute of Physical Chemistry there from 1907 to 1930. He died at Göttingen on Dec. 17, 1938. Tammann made fundamental investigations of the changes in the condition of matter and their dependence on temperature and pressure and also studied the reactions of matter in a hard and brittle condition. Especially valuable were his introduction of thermal analysis in the construction of constitutional diagrams of metals, and his researches into the nature and structure of alloys.

Among Tammann's publications were *Lehrbuch der Metallurgie* (1914; 4th ed., 1932); *Die chemischen und galvanischen Eigenschaften von Mischkristallreihen und ihre Atomverteilung* (1919). He was an editor of *Zeitschrift für anorganische und allgemeine Chemie*.

See W. E. Garner, "The Influence of Gustav Tammann," *Chemical Age*, vol. 66 (1952). (O. W. K.)

**TAMMANY HALL**, popular name of the executive committee of the Democratic Party of New York County, sometimes applied to the entire party structure in the county or in the city. From about 1800, with only occasional intermissions, as a political organization it was important in the city, and it exercised considerable influence in state administration and national affairs. Tammany societies patterned after the New York organization were formed in other states in the early 1800s but did not attain great importance.

**Origin.**—Before the American Revolution groups proclaiming fealty to King George III were organized in societies bearing the names of St. George, St. Andrew, and St. David. As a countermove, the revolutionists formed associations called the Sons of Liberty or the Sons of St. Tammany, the latter after Tamanend, a Delaware Indian chief (fl. 1682–1700) famed for wisdom, benevolence, and love of freedom, with the "saint" thrown in as a

form of ridicule. After the achievement of American independence, these associations dissolved.

During the 1780s the leaders of the aristocratic and propertied elements of New York city and state successfully managed to limit the suffrage to freeholders and to strengthen the Society of the Cincinnati, a group of former officers of the Revolutionary Army with centralist and monarchical tendencies. To resist these influences, William Mooney, an upholsterer in New York City, founded the Society of St. Tammany or Columbian Order, on May 12, 1789, a few days after the inauguration of George Washington as the first president under the Constitution. His purpose was the creation of a national society that would be native in character and democratic in principle and action. Its officers were given Indian titles; the society's chief was grand sachem and his fellow chiefs, sachems.

For more than three decades after its organization, Tammany represented the middle-class opposition to the pretensions and power of the aristocratic party. Its "democracy" did not incorporate the aspirations of the lower economic groups. In that period it also lost its national and nonpolitical character and became intimately identified with politics in New York City.

Under the control of Aaron Burr until his political downfall after killing Alexander Hamilton in a duel in 1804, the society had an influential share in bringing about victories of the Republican (later called the Democratic) Party and was richly rewarded, particularly by Thomas Jefferson after he became president in 1801.

**Organization.**—Criticisms made by the opposition that a private society was engaging in politics resulted in a separation of the Hall's social and political functions. In 1805 the Society of St. Tammany obtained from the legislature a charter of incorporation as a benevolent and charitable body to give relief to members and others. Politically, the Democratic Party was organized as an apparently distinct body; in reality, however, the society's sachems controlled the political mechanism and prevented hostile factions from meeting in the society building, Tammany Hall.

The political organization initiated at that time consisted of general, nominating, corresponding, and ward committees. In the general committee was vested the power of convening the party's meetings and of making all necessary arrangements for elections. Composed originally of 30 members, three from each of the city's ten wards, this committee was gradually expanded until it had many thousands of members penetrating every section of the city. The real power consequently passed into the hands of the ward leaders, later organized as the executive committee of the party.

**Boss Rule.**—As early as 1806–07, revelations of widespread corruption of Tammany city officials resulted in the removal of the controller, the superintendent of the almshouse, the inspector of bread, and others. Despite such proved charges, many of the removed officials, including the society's founder, remained powerful Tammany sachems.

The bitterest opponents of Tammany were the Irish immigrants who were ineligible to be members of the "native-born patriots." As a protest against Tammany bigotry, hundreds of Irish migrants broke into a general committee meeting on the evening of April 24, 1817. Within a few years, the propertied leaders of Tammany were forced for their own preservation to take in the immigrants, naturalize and vote them, and join in the fight for manhood suffrage.

In the 1830s the pressures exerted by the Workingmen's Party and its successor, the Equal Rights Party, forced the general committee to oust the banking and merchant leaders. The election of its grand sachem, Martin Van Buren, as president of the United States in 1836 redounded to Tammany's prestige. Within a few years, however, the immigrant groups, organized into gangs, came under the control of the astute, unscrupulous, and engaging Fernando Wood, several times mayor of New York, who used them to break with and later control Tammany. Grand Sachem William M. Tweed (q.v.) initiated complete boss domination of the Hall in 1868. Corruption reached a climax under Tweed, when New York City was plundered of more than \$200,000,000. Tweed died in jail but most of his confederates retained their wealth. Throughout the world, Tammany became synonymous

with corruption and was the subject of some of Thomas Nast's most effective cartoons.

John Kelly, who succeeded Tweed, induced the leading reformers—Samuel J. Tilden, August Belmont, and Horatio Seymour—to serve as sachems. The real resuscitating factor, however, was the attachment of the tenement house masses to the district leaders, who could be counted on to help poor families in distress. The helping hand outweighed all of the denunciations. Richard Croker in 1886 and his successor in 1902, Charles F. Murphy, carried on the façade of making liberal avowals and supporting progressive candidates for the top of the ticket but failed to curb corruption within the administrative machinery.

**Reform.**—After Murphy's death in 1924, Judge George W. Olvany became county leader and with the assistance of Gov. Alfred E. Smith sought to alter the character of the Hall. On March 16, 1929, Judge Olvany resigned and was succeeded by a leader of the old school, John F. Curry. Revelations of corruption in Mayor James Walker's administration, as shown in the Seabury Report, discredited Curry but he remained in power until successive defeats of Tammany candidates led to his replacement by James J. Dooling in July 1934.

During the 12 years of Fiorello LaGuardia's reform administration, Tammany declined in power and was eclipsed by the more powerful Brooklyn and Bronx Democratic leaders. Many Democratic Party candidates repudiated Tammany. The organization found itself in dire financial condition and had to give up its headquarters in the building maintained by the Tammany Society. A succession of county leaders—Timothy J. Sullivan, Michael J. Kennedy, and Edward Loughlin—promised the elimination of corruption and pledged leadership for good government but failed to induce public confidence in the Hall. In the election of 1945, however, Tammany once more established its ability to turn out a sizable vote. The newly elected mayor, William O'Dwyer of Brooklyn, sought to control Tammany by ousting Loughlin and forcing the acceptance in March 1947 of Frank J. Sampson as county Democratic leader.

Lacking the support of the district leaders, Sampson functioned as a figurehead and was soon replaced by Hugo Rogers, Manhattan's borough president. A bitter struggle between city hall and Tammany ensued, reflected in a series of district leadership fights in the 1949 primaries in which the regular organization defeated a group of insurgent reformers. Rogers, however, was ousted in favour of Carmine G. De Sapio.

Pressures from within and outside the organization brought about a reconciliation of Mayor O'Dwyer and the new Tammany leader but charges of underworld control of some district leaders and of others high in Tammany councils led to insistent demands for reform. Acting Mayor Vincent R. Impellitteri, who had been denied the regular nomination, ran as an independent, anti-Tammany candidate in the special election in 1950 and beat the organization decisively.

The Hall lost other important local and city elections to independent Democrats, moreover. De Sapio managed, however, to stave off threats to his leadership in the primary campaigns of 1951 and 1953. In 1953, he joined with Edward Flynn of the Bronx to support Manhattan Borough Pres. Robert F. Wagner, Jr., for the Democratic mayoralty nomination. After Flynn's death and Wagner's nomination and election, De Sapio was recognized as an important leader. He succeeded Flynn as Democratic national committeeman and also became secretary of state for New York. De Sapio's rule was criticized by reformers, including Mayor Wagner, who opposed his leadership in 1961 and won reelection that year. Four years later, John V. Lindsay, who had been elected to the U.S. Congress as a Republican, ran for mayor as a Republican-Liberal and defeated the regular Democratic candidate.

See Gustavus Myers, *The History of Tammany Hall* (1917); M. R. Werner, *Tammany Hall* (1928); W. Riordon, *Plunkitt of Tammany Hall* (1948). (M. B. D.; M. R. W.)

**TAMMERFORS:** see TAMPERE.

**TAMMUZ**, Hebrew form of DUMUZI ("true-son"), a god of ancient Babylonia. In all periods of Sumerian and Akkadian literature, his name when written is prefixed by the sign for deity.

Dumuzi is first mentioned in a Sumerian list of divine names found at Shuruppak (modern Tell Fa'rah, in lower Iraq) and composed about the middle of the 3rd millennium B.C. Thereafter, he is named in texts found at Lagash, Umma, Drehem, and Ur. During the dynasty of Akkad (c. 2350–2230 B.C.) the Lagash calendar included a "month of the feast of Dumuzi." In a somewhat later account of the overthrow of the Gutí (the dynasty that succeeded the Akkadian), their conqueror, Utukhegal, king of Uruk, says "Inanna is my support, Dumuzi, the *ama-ushumgal-an-na*, has declared my destiny." The Sumerian title which follows the name Dumuzi means "the heavenly dragon of the Mother" (i.e., of Inanna; though a reference to "date clusters" is preferred by some scholars). *Ama-ushumgal* occurs as a personal name on some of the earliest Sumerian documents.

During the 3rd dynasty of Ur (end of the 3rd millennium B.C.) there was at Lagash a temple of Dumuzi, possessed of much property administered by officials, in which offerings were made to him. The 6th month at Lagash and the 12th month at Umma, neighbour of Lagash, were his festival months. By contrast, in contemporary tablets from Ur, the well-documented capital city of this dynasty, Dumuzi is not mentioned except in personal names derived from his name. No temple or offerings are recorded in his honour, and no festival month of Dumuzi occurs in the calendar used at Ur during the period in which most of the tablets are dated. It would appear therefore from the 3rd-millennium evidence that his cult was limited, for the most part, to Lagash and its neighbour Umma, and from this evidence nothing can be discovered about his relationship to the Sumerian deities or his place and function in popular story.

On these aspects, however, there is evidence from texts of the first half of the 2nd millennium B.C. Much of this evidence was not known to scholars before World War II. It lends no support to earlier constructions and interpretations of the Tammuz story or to alleged parallels with Adonis or Osiris.

Sinidinnam of Larsa states that he has "gratified the hearts of Shamash and Dumuzi." Larsa was the chief cult centre of Shamash (q.v.; Sumerian Utu), the sun-god, who is prominent in stories of Inanna and Dumuzi. On the other hand, Hammurabi (about 50 years later) does not name Dumuzi in the long list of deities in the prologue and epilogue of his code. A composite text of this period, the Sumerian king list, is authority for a tradition that Dumuzi was a king of ancient Sumer. The name is given both to a pre-diluvian king of Bad-tibira in the region of Uruk (biblical Erech), who reigned for 36,000 years, and to a post-diluvian king of Uruk, who reigned for 100 years. In the former entry he is described as a shepherd. In the latter he is a "SHU. PES. fisherman," of uncertain meaning. In both he is mortal.

The earliest evidence of the association of Dumuzi and Inanna (see ISHTAR) occurs in the quotation from Utukhegal quoted above. In a dialogue written in Sumerian and dating from the early 2nd millennium B.C., involving Enkimdu, the farmer, and Dumuzi, the shepherd, the sun-god Utu advises his sister Inanna to choose Dumuzi rather than Enkimdu for husband. This she does after hearing each recount the benefits he confers on mankind. In this dialogue, Dumuzi, "whose fat is good, whose milk is good," belongs with sheep, lambs, and kids. The dialogue probably reflects an older tradition and thus supplies something which is not discernible in the purely administrative texts and royal inscriptions of the Sumerian period. A text of the 1st Babylonian dynasty (c. 1800–c. 1600) represents Inanna in search of Dumuzi *ama-ushumgal-an-na*. She seeks "the shepherd" "in the sheepfold" and revives him with food, drink, and music.

An important feature in the story of Dumuzi is his presence in the underworld. A Sumerian version of Inanna's "Descent to the Underworld" appears to offer an explanation of this. It relates that on her return from the lower regions Inanna goes to the Sumerian city Kullab of which Dumuzi, her husband, is guardian. He receives her seated and wearing robes of state. Enraged by such *hauteur* Inanna bids the seven demons who have escorted her from below to "carry him off" to the underworld. This they presumably do, in spite of Dumuzi's tearful appeals to Utu. This suggests that the presence of Dumuzi in the underworld was

thought of as a punishment and not as an incident in his search for Inanna. In later literature Enkallu, the underworld, is described as "the house of Tammuz," and he as "shepherd of the earth." The "earth" is another synonym for the underworld, called also Arallu, of which Dumuzi is named "lord." The myth of Adapa (see ADAPA) states that Tammuz and Gizzida disappeared from "the land," *matu*, a name also frequently employed to indicate the underworld. His disappearance is the theme of many laments, and there is no mention or celebration of a resurrection. He has disappeared to "the land of no return." There he is said to keep in check the demons who torment the sick. He is, however, rarely invoked in exorcisms. The Semitic version of Ishtar's "Descent" closes with a reference to a washing, anointing, and clothing of Dumuzi. This is probably a reference to an image of Dumuzi, possibly on the occasion of a lying-in-state, and to rites of the *takliltu* ceremony at which such ritual washings, etc., were performed.

An explanation of the wailings for Dumuzi is given in the Epic of Gilgamesh (see GILGAMESH, EPIC OF). Ishtar smote Dumuzi "the shepherd" and "the lover of her youth," bruising his wing. For this reason he sits in the woods crying, "my wing, my wing." Ishtar ordains annual wailings for him. The majority of these laments are composed in the Sumerian language; some have an interlinear translation in Akkadian.

The city chiefly associated with Dumuzi is Uruk, the ancient Sumerian city, of which he together with Shamash and Gilgamesh was protector in the time of Utukhegal. Kullab, to which Inanna returned from the underworld, was part of Uruk. In northern Iraq there was a month of Dumuzi but little else to suggest that he was much honoured in Assyria. Mari, in southeastern Syria, also had this month in its calendar. In Palestine, there were wailings at Jerusalem: "and behold, there sat women weeping for Tammuz" (Ezek. 8:14). (The Masoretic text of Ezek. 8:1 gives the sixth month as the date of this wailing but the Septuagint gives the fifth.) The Jewish colony at Elephantine, an island opposite Aswan in Egypt, included the month of Tammuz in its calendar during the 5th century B.C. There is no evidence that Tammuz was honoured by the Hebrews before the time of Ezekiel, who, according to tradition, exercised his ministry in Babylonia, the early home of Tammuz cult.

For the context of the worship of Dumuzi, see BABYLONIA AND ASSYRIA: Religion: Sumerian Pantheon: Herding Regions.

**TAMPA**, the seat of Hillsborough County, Fla., U.S., the principal manufacturing city and agricultural centre on the west coast of the state, lies at the mouth of the Hillsborough River as it enters an arm of Tampa Bay. The population in 1960 was 274,970, an increase of 120.5% in the decade; that of the Tampa-St. Petersburg standard metropolitan statistical area (Hillsborough and Pinellas counties) was 772,453, an increase of 88.8%. (For comparative population figures for both Tampa and St. Petersburg, see table in FLORIDA: Population.) (See also SAINT PETERSBURG.)

**History.**—Tampa was the name of an Indian settlement recorded by historians in the 16th century after Spanish explorers, including Hernando de Soto, and missionaries landed in its vicinity. In November 1823 Col. George M. Brooke was directed to establish a military post at Tampa Bay when the U.S. Army began the removal of Seminole Indians from north to south Florida, and Ft. Brooke was erected there in 1824. The fort was also active in the seven years of warfare (1835–42) brought on by attempts to remove the Indians to the west, and during the American Civil War it was bombarded and the port blockaded to prevent the shipment of cattle from Tampa to Cuba. Tampa was incorporated in 1855. In 1886 Vicente Martinez Ybor induced several cigar

manufacturers to move there after they had been driven out of Havana, Cuba, by revolutionary disorders and from Key West because of labour disturbances and a disastrous fire. Tampa became a world leader in the production of clear Havana handmade cigars.

The greatest developer of Tampa was Henry B. Plant, who made it an international port and tourist resort. In the mid-1880s he connected the city by a standard-gauge railway with lines to the north; he also inaugurated steamship service to Key West and Havana. In 1891 Plant opened the Tampa Bay Hotel, a dark-red-brick castle of Moorish architecture topped by silvery domes and 13 minarets on which he had lavished \$3,000,000. Five stories in height and extending over a six-acre tract on the Hillsborough River, the sprawling edifice became one of the popular luxury hotels of the world.

During the Spanish-American War, about 30,000 soldiers were camped in and near the city before embarking for Cuba. Cigar makers supported the Cuban independence movement, their aid being organized by the Cuban patriot José Martí; the cottage in Tampa where he made his headquarters is now a shrine.

The Latin quarter, known as Ybor City, which accounts for about 15% of the population, is the home of Spaniards and Cubans connected primarily with the cigar industry. They maintain their own imposing social clubs and hospitals. Their restaurants have an international reputation.

In the mid-1920s the man-made Davis Islands were created in the bay to provide sites for hotels, residences, apartments, a hospital and an airport. A landscaped six-mile boulevard bordering the crescent-shaped bay forms a scenic residential section.

**Commerce, Industry and Transportation.**—Tampa is a port of entry; after the opening of the Panama Canal in 1914 it became one of the most important ports on the Gulf of Mexico. The impact of the citrus industry is an important factor in the economy of Tampa. A large percentage of all phosphate mined in the U.S. is extracted from the adjoining county; much of it is shipped from Tampa. In addition to the numerous cigar factories there are more than 700 manufacturing plants. The tourist business is also important in the economy. The city is well served by rail and air lines as well as by harbour facilities.

**Education and Recreation.**—The University of Tampa, a private institution chartered in 1931, in 1933 was given a 99-year lease on the Tampa Bay Hotel building by the city. The state-supported University of South Florida was established in 1958 and opened in 1960. Features of the winter season in Tampa are the Gasparilla and Latin-American pageants and festivals, baseball, golf, tennis, and sailing. (A. J. H.)

**TAMPERE** (Swedish TAMMERFORS), the second largest town of Finland and the seat of a bishopric, is situated in Häme (Hämeen lääni (county), 116 mi. (187 km.) NNW of Helsinki by rail. Pop. (1960 est.) 127,260. An important cultural, industrial, and communications centre, it occupies a narrow isthmus traversed by the Tammerkoski rapids which flow from Lake Näsijärvi to Lake Pyhäjärvi. It is a modern town with wide esplanades, parks, and gardens, and notable examples of 20th-century Finnish architecture and sculpture. The oldest building is the 15th-century stone church of Messukylä. The cathedral (Lars Sonck; 1907) is in the national-romantic style. Among works by prominent modern architects are the cemetery chapel (1960) by Viljo Revell (designer of the Toronto City Hall); the Finnish Institute of Social Sciences begun (1961) by Toivo Korhonen; and the open-air Pyynikki Summer Theatre, with a revolving auditorium (1959), the first of its kind in the world, by Jaakko Iivesskoski.

Tampere is a junction of railway lines from Helsinki and to the north and west; there are air connections with Helsinki Vaasa, Jyväskylä, Pori, Stockholm, and Copenhagen and passenger services on the lakes. The Tammerkoski provides power for Finland's biggest concentration of industry outside Helsinki, producing mainly textiles, machinery, and footwear. The first cotton mill was founded by a Scot, James Finlayson, in 1820, and industrial development was encouraged by fiscal privileges enjoyed by the town during 1821–1905. Tampere received its charter in 1779. It

was the scene of an important battle in the Finnish War of Independence of 1918. (E.-S. Kv.)

**TAMPICO**, a city and leading port of Mexico, in the state of Tamaulipas, on the north bank of the Pánuco River, about 6 mi. from the Gulf of Mexico. In summer the climate is hot and humid, although a sea breeze modifies the temperature somewhat. In winter the temperature falls to freezing on occasional days when northers blow down along the Gulf Coast. Tampico is almost surrounded by swampy lands and lagoons.

The eastern and poorer part of the town stands on low ground only two or three feet above the river, and is subject to inundations. However, a modern sewer system, up-to-date street paving, and a better water supply, constructed after the beginning of the 20th century, greatly improved the sanitary conditions and reduced the death rate from epidemics. The western part rises about 150 ft., consists largely of residential districts and is provided with still better sanitary equipment. The business section is well built, largely of stone and brick, while many of the newer structures are of reinforced concrete and rise to six and seven stories. The city is well supplied with gas and electric light.

Tampico has excellent railway facilities, road connections with the Pan-American highway, and air services available to Mexico City, Veracruz, Brownsville, Tex., and other points. Although a bar exists at the mouth of the Pánuco River, jetties were built and the depth increased by dredging, so that vessels drawing up to 33 ft. can approach the waterfront of the city, while scows and other boats of light draft can navigate the river for more than 100 mi. upstream.

The Chijol Canal, begun in 1901, affords a waterway 6 ft. deep and 25 ft. wide for about 75 mi. southward through the oil fields to Tuxpan. Modern port works, spacious enough to accommodate at the wharves 14 vessels at a time, steel sheds and warehouses, a union railway station within easy reach of the waterfront, and excellent equipment for loading oil tankers make Tampico the most up-to-date harbour in Mexico.

Tampico owes its importance to four of the most productive oil fields in the country (the Ebano, Pánuco, Huasteca, and Tuxpan) which are situated within about 100 mi. of its site. Until 1901 it was a second-rate port, outlet of the fertile but relatively underdeveloped hinterland, with a reputation for unhealthful and unsanitary conditions. The rapid exploitation of petroleum resources resulted in a marked increase of population from about 10,000 in 1900 to 24,980 in 1921, to 82,475 in 1940, to 94,342 in 1950, and to 122,535 in 1960. For several years Tampico ranked as the greatest oil port in the world. Pipelines lead from the nearby fields, while fleets of scows bring oil from farther up the river. Pipelines and barges together are capable of transporting approximately 1,200,000 bbl. of oil daily from the fields to the port of Tampico.

Up river from the port agricultural activities were stimulated, fruits, vegetables, and grains being grown to supply the local food demands. Modern commercial establishments are stocked with U.S. and European goods. Hotels, clubs, restaurants, and places of amusement are numerous and well served. Because of high prevailing wage rates, the standard of living is generally higher than in most Mexican cities. Tampico is also noted as a vacation resort with excellent bathing, golfing, hunting, and fishing.

Besides those connected directly with the oil business, the industrial establishments of Tampico include many for the handling and repair of oil well machinery, yards for the building of river boats, an electric light and power plant, factories for making ice, clothing, and fruit preserves, sawmills, etc. In addition to petroleum, the exports include silver bullion (from San Luis Potosí, Aguascalientes, Torreón, and Monterrey), isle fibre, sugar, hides, live cattle, cottonseed cake, honey, fustic, sarsaparilla, coffee, and copper ores.

Tampico grew around a monastery which was founded in the ruins of an Aztec village by Andrés de Olmos, a Franciscan friar, in 1532. It was destroyed in 1683 by pirates and not reoccupied until 1823 when Gen. López de Santa Anna ordered that the site should be settled.

In 1829 a Spanish force under Isidro de Barradas was defeated at Tampico by Santa Anna. It was briefly occupied by U.S. forces during the Mexican War and again in 1862 by the French. The arrest of some American sailors in Tampico on April 9, 1914, led to the bombardment and occupation of Veracruz on April 22, 1914, by the U.S. Navy. (J. W. Mw.; R. B. McCr.)

**TAMWORTH**, a city of New South Wales, Austr., lies on the Peel River 1,279 ft. (390 m.) above sea level, 285 mi. (459 km.) N of Sydney by rail. Pop. (1961) 18,984. The city possesses several schools and a notable art gallery. The headquarters of Australia's only decentralized airline, it has regular air services with Sydney and Brisbane. It is the centre of an extensive agricultural district, and its industries include light engineering, flour and timber milling, egg processing, and the production of starch and gluten. Tamworth was the first Australian city to install electric street lighting (1888), an event celebrated by an annual "festival of light." (E. W. W.)

**TAMWORTH**, a market town and municipal borough in the Lichfield and Tamworth parliamentary division of Staffordshire, Eng., 15 mi. NE of Birmingham by road. Pop. (1961) 13,646. Area 4.2 sq.mi. It lies at the junction of the Tame and Anker rivers, in open country with wooded uplands. Offa, overlord of Mercia, built a palace there in the 8th century and surrounded the burgh by the great entrenchment known as Offa's dyke. During the 9th century Tamworth was destroyed by the Danes, but in A.D. 913 Aethelstred, daughter of Alfred the Great, defeated them and built a timbered stockade at the junction of the rivers where the present castle stands. William the Conqueror bestowed the manor upon Robert de Marmion, who built the Norman castle, the walls and keep of which remain. It was largely restored in the Jacobean period. Tamworth, a borough since Saxon times, once possessed a royal mint, dating from Aethelstan's reign. Originally half the borough was in Staffordshire, the other half in Warwickshire, but in 1319 Edward III granted the Warwickshire half to the burgesses by letters patent. The town was incorporated by Elizabeth I in 1560 and a further charter was granted by Charles II in 1663. The whole borough was transferred to Staffordshire in 1889. The church of St. Editha (8th century) was rebuilt, after the Danes had burned it, by king Edgar who made it collegiate in A.D. 963. The existing Decorated building was erected after a fire in 1345. The grammar school, granted a charter by Elizabeth I in 1588, once formed part of the collegiate church. Guy's Almshouses (1678) were endowed by Thomas Guy, founder of Guy's Hospital, London, who also built the town hall over the open market in 1701. An ancient fair in honour of St. Swithun is still held (July 26). Two members of Parliament were returned by the borough from 1562 to 1885. Sir Robert Peel represented it during the first half of the 19th century. Tamworth, the centre of an agricultural and coal-mining area, specializes in agricultural engineering, textile weaving, paper making, the manufacture of asbestos and aluminum ware, and the making of terra cotta bricks from local clay.

**TANA LAKE**, the largest lake of Ethiopia, lies in the north-west on a high plateau about 6,000 ft. (1,830 m.) above sea level. It forms a reservoir for the Blue Nile (known in Ethiopia as the Abbai), which drains from the southern extremity near Bahr Dar. The lake's surface covers 1,418 sq.mi. (3,673 sq.km.), with a surrounding drainage area of 4,500 sq.mi. (11,655 sq.km.). The alluvial plains of Dembea on the northern shore and Fogera on the east indicate that at one time the lake had been more extensive. Where the lake has been dammed by a lava barrier near Bahr Dar, the Abbai crosses the southern ledge, forming the spectacular Tis Esat Falls. The drop at this point has been harnessed for hydroelectric power. Though the source of the Abbai is popularly believed to be the Little Abbai River, to the south near Mt. Amedamit—the source identified by the British explorer James Bruce about 1770—the flow from the inlet of this stream to the outlet of the Abbai is probably part of a general flow toward the outlet at the southern end of a bay some 11 mi. long. Many narrow promontories (the largest, Gorgora, in the north) jut into the lake, separating small alluvial plains. Of the small islands fringing the shores, most notable are the two larger inhabited islands.

Dek and Dega, at the southern end; both contain historic churches famed for medieval manuscripts and paintings.

With abundant rainfall, the Lake Tana region produces grains, oilseeds, and coffee. There is also some cattle raising. A new road now connects Bahr Dar with Gorgora and there is regular motor-boat service across the lake. The ancient *tanqua* (papyrus reed boat) is used for fishing.

(G. C. L.)

**TANAGER**, the name for members of the songbird family *Thraupidae* (formerly *Tanagridae*) containing 197 species. They are small to medium-sized birds of rather generalized form, with medium-sized wings, feet and tails. The beak is heavy and somewhat similar to that of their nearest relatives, the sparrows. As a group tanagers are noted for the brilliancy of their plumage, though they have developed no ornamental tufts or plumes. Reds, yellows, greens, blues and blacks in solid colours are common and sometimes arranged in striking patterns. The

HAL H. HARRISON FROM NATIONAL AUDUBON SOCIETY

MALE SUMMER TANAGER (*PIRANGA RUBRA*) AND YOUNG

sexes may be coloured similarly, or the female may be much duller than the male. In some species, however, both sexes are dull-coloured. No tanagers are notable songsters, but some have simple songs of pleasing quality.

The family is entirely confined to the new world, with its centre of abundance in the tropics. Only four species range north to the United States, and two regularly to Canada, and these are all migratory. Tanagers are arboreal birds, living in tree tops, undergrowth or shrubbery. Fruit is an important part of the diet of many species, and some feed almost entirely on mistletoe berries. Other species eat some insects.

The nest is a shallow, open structure. The eggs, two to four in number, may be white or bluish, immaculate or spotted. Monogamous pairing seems the rule and, in some species at least, while the female alone incubates, both sexes care for the young. In the tropics some species remain in pairs throughout the year.

When feathers were popular in millinery, brilliant tropical tanagers were often used as hat trimmings.

The best-known species are probably those of the United States, especially the scarlet tanager (*Piranga olivacea*), the male scarlet with black wings and tail, the female olive and yellowish; the summer tanager (*Piranga rubra*), with an all-red male; and the western tanager (*Piranga ludoviciana*), with the male yellow with reddish head and black wings and mantle. (A. L. Rd.)

**TANANARIVE:** see *ANTANANARIVO*.

**TANAQUIL**, the semilegendary Etruscan wife of Lucumo, who became Tarquinius Priscus (see *TARQUIN*), fifth king of Rome. She was a social climber, and because of her husband's lowly position in their own city (Tarquinii) she urged a move to Rome, where, by her prophetic powers, she foresaw that their fortunes would improve. There Lucumo adopted a Latin name Lucius Tarquinius, and she reportedly changed hers to Gaia Cae-

cilia. On her husband's death, she made her son-in-law, Servius Tullius (*q.v.*), king. She was famous for her spinning and weaving, and there was a statue of her as Gaia Caecilia in the Temple of Semo Sancus, where her distaff and spindle were preserved as relics. A robe she had woven was similarly kept in the Temple of Fortune. Thus she became a model of virtue for Roman brides. Tanaquil and Gaia Caecilia are probably distinct personalities who somehow became associated at an early date.

See Livy, i, 34, 39, 41; Pliny, *Natural History*, viii, 74; Plutarch, *Roman Questions*, 30. (R. B. Lo.)

**TANA RIVER**, with a length of 440 mi. (708 km.), is the longest river of Kenya. Its numerous headwaters, among which the Sagana is considered to be the actual source of the river, rise in the high rainfall areas of the Aberdare Range and Mt. Kenya. These streams are collected and their water is carried northeastward along the ungraded section of the river containing Seven Forks, or Gtaru, Falls (440 ft. [134 m.]) into the semi-desert landscape through which the Tana flows in its middle course. Describing a wide arc, the river gradually assumes a southerly direction and opens out into the wide valley where it pursues an unstable and extremely sinuous course on a floodplain liable to widespread inundations. It reaches the Indian Ocean at Kipini, but a former outlet lies 20 mi. to the southwest. The river is navigable by launch, sometimes with difficulty, for 200 mi. (320 km.) upstream. In the upper Tana catchment Sasumua reservoir provides water for Nairobi; Kindaruma, at Seven Forks, is the site for a 40-megawatt hydroelectric scheme, and the Mwea-Tebere irrigation settlement has rice as its chief cash crop. On the forest-clad banks of the middle Tana the riverine Pokomo practise subsistence cultivation, and at Galole cotton is grown on a government irrigation scheme. (S. J. K. B.)

**TANBARK OAK** (*Lithocarpus densiflora*), an ornamental evergreen allied to the oaks, both of which belong to the beech family, Fagaceae. The tanbark oak, native to southern Oregon and northern California, is a tall tree of 75 to 100 ft., with alternate, leathery, toothed, more-or-less oblong three- to five-inch leaves covered on the underside with densely matted hairs that disappear in time.

The fruit is an acorn about one inch long. The tree is valued chiefly for its bark, which is an important source of tannin, but it is also an attractive ornamental. The waste bark of this tree and others is the tanbark used as a ground cover. (J. M. BL.)

**TANCRED** (d. 1194), king of Sicily from 1190, of the Norman dynasty of Hauteville, was a natural son of King Roger II's son Roger, duke of Apulia (d. 1148), by a lady of the family of the counts of Lecce. During the reign of his uncle William I (from 1154) he conspired against the government, but eventually had to take refuge in Constantinople. Returning to the kingdom on William I's death (1166), he lived in concord with William II and obtained the countship of Lecce in 1169.

Short and ungainly, but quick-witted, Tancred showed ability as commander of the fleet in the expedition of 1185 against the Byzantines. When William II died (1189), a faction of the Norman nobility, reluctant to let the Sicilian crown go to Roger II's daughter Constance, wife of the Hohenstaufen German king Henry VI (*q.v.*), elected Tancred king. He was crowned at Palermo early in 1190, but his election split the anti-Hohenstaufen party, since some who had preferred a rival candidate (Roger of Andria) went over to Henry's side. In October, moreover, Richard I (*q.v.*) of England, brother of William II's widow Joan, seized the citadel of Messina: Tancred had to satisfy his heavy claims to money and treasure before Richard would depart (spring 1191).

Helped by the towns, to which he made concessions, Tancred suppressed rebellion in Apulia and Campania. In summer 1191 Henry gave up his siege of Naples. Henry was about to attack again when Tancred died, in Palermo, on Feb. 20, 1194, leaving his widow Sibyl (Sibylla) of Acerra as regent for his son William III. (E. Po.)

**TANCRED** (c. 1076–1112), Norman crusader from Sicily who was twice regent of Antioch (see *CRUSADES*), was a son of Marquis Odo and Emma, Robert Guiscard's daughter. He went with Bohemund I (*q.v.*) to Constantinople in 1096 but avoided taking the

oath of allegiance which the other crusaders swore to the Byzantine emperor Alexius I. After Nicaea was taken, however, he paid homage to Alexius. He left the main crusading body after the capture of Heraclea-Cybistra and went south through the Cilician Gates to capture Tarsus, which Baldwin of Boulogne (later Baldwin I of Jerusalem), following with a stronger force, soon compelled him to relinquish. He then pressed on to take two other east Cilician cities held by the Armenians, Adana and Mamistra (Mopsuestia), where Baldwin again caught up with him, and there was a skirmish between the two crusading forces followed by a reconciliation. Tancred then took Alexandretta (Iskenderun) before rejoining the main crusading armies by now approaching Antioch (1097), which they took after siege in June 1098. Tancred played a leading part in the crusader conquest of Jerusalem in 1099, having previously taken Bethlehem. He then took Nablus, and was prominent in the crusaders' defeat of the Egyptians near Ascalon. He strengthened the position of Jerusalem by conquering Galilee, and took the title of prince of Galilee. After the death of Godfrey of Bouillon, crusader ruler of Jerusalem (1100), Tancred took Haifa, and supported Daimbert, the new Latin patriarch, in offering Jerusalem to Bohemund, but in fact Baldwin of Boulogne became his brother Godfrey's successor.

Tancred then went to Antioch as regent (Bohemund having been captured by the amir Danismend) and gave up Galilee to Baldwin (1101). He recaptured the east Cilician cities, now in Byzantine hands, and then attacked the port of Latakia (Laodicea), also held by the Byzantines, having compelled Raymond IV of Toulouse to withdraw his troops from it and to give up all claims to north Syria. In early 1103, after nearly a year's siege, Tancred took Latakia. Shortly afterward Bohemund, now ransomed, took over his principality of Antioch from Tancred, who grudgingly relinquished also the cities he had captured as regent. However, the following year he was appointed regent of Edessa after Baldwin II of Edessa was taken prisoner in an unsuccessful crusader attack on Harran led also by Bohemund and Tancred. In 1104 the Byzantines recaptured the east Cilician cities and Latakia, and Bohemund went to Europe to seek reinforcements, leaving Tancred as his regent again in Antioch. Tancred won back from the Turks the city of Artah (1105), and then took Apamea (1106). In 1108 he retook Latakia and the east Cilician cities from the Byzantines, and refused to hand them back, regardless of the provisions of the Treaty of Devoll (1108) which Bohemund, his overlord, had signed after being defeated at Durazzo by Alexius. In the same year he unwillingly relinquished Edessa to Baldwin II, now released, and in 1109 was reconciled with him outside Tripoli, which the united crusaders then successfully besieged. Another reconciliation was required the following year, when Baldwin accused Tancred of treachery. Tancred carried out successful campaigns against the Turks of northern Syria before he fell ill and died at Antioch on Dec. 12, 1112.

The Tancred of Tasso's *Gerusalemme liberata* bears little resemblance to the historical character (see TASSO, TORQUATO).

See S. Runciman, *A History of the Crusades*, vol. 1-2 (1951-52).

**TANDY, JAMES NAPPER** (1740-1803), Irish politician, revolutionary, and popular hero, was born in Dublin. His family represented Trim and Athboy, County Meath, in the Irish Parliament for about 50 years from 1695. Starting as a small tradesman, he became a land agent and rent collector. He entered politics as a representative of the guild of merchants on the Dublin Common Council, where he made his mark by vehement denunciations of corruption. He joined the Irish Volunteer movement (see IRELAND: History) in the duke of Leinster's regiment, and when the independence of the Irish Parliament was announced in Dublin on May 27, 1782, his forces commanded the approaches to the parliament house. His influence waned after 1784 with the decline of the Volunteer movement.

A member of the Whig Club, he soon showed enthusiasm for the principles of the French Revolution, and he led the advanced Radical Party in Dublin city. In 1791 he helped Theobald Wolfe Tone and Thomas Russell to found a branch of the Society of United Irishmen in Dublin and became its first secretary. In February 1793, charged with having taken the oath of the De-

fenders' Society, he fled from Ireland and eventually arrived in Philadelphia, Pa., at the end of 1795. He went to Paris in 1798 and became jealous of Tone's success there. The French government appointed Tandy a general and sent him to Ireland to raise an Irish army. He landed at Rutland Island, off the coast of County Donegal, on Sept. 16, 1798, but learning of the failure of Gen. J. J. Humbert's landing in Connaught, he escaped by sea the same day.

Returning to France via Norway he was captured in Hamburg (November 1798). Under pressure from the English government in September 1799 the Hamburg City Council handed him over to the British. Sentenced to death at his trial in Ireland (April 1800) he was eventually released unconditionally after Napoleon Bonaparte had demanded his extradition. He received a public ovation on arriving at Bordeaux (March 1802), and died there on Aug. 24, 1803. Tandy's name is remembered in the Irish ballad "The Wearing of the Green": "I met with Napper Tandy, and he took me by the hand, And he said 'How's poor old Ireland, and how does she stand?'" Though remembered for his picturesque adventures and his irresponsible exuberance as a politician, his career contained no real achievements. (D. G.)

**TANEV, SERGEI IVANOVICH** (1856-1915), Russian composer and theorist, who as the principal practitioner of counterpoint was an influential figure in 19th-century Russian music, was born on Nov. 25 (new style; 13, old style), 1856. He studied composition with Tchaikovsky and piano with N. Rubinstein in Moscow. In 1878 he interrupted his career as a pianist in order to succeed Tchaikovsky at the Moscow Conservatory, where he served as director from 1885 to 1889, subsequently holding the post of professor of counterpoint and fugue. In 1895 his operatic trilogy *Oresteia* was produced in St. Petersburg. In 1905 he resigned his professorship in protest at measures against the threatened revolution and resumed his career as pianist and composer. In 1909 he completed his two-volume work on counterpoint in the strict style, on which he had worked for 20 years. His masterpiece, a setting of A. S. Khomyakov's "On the Reading of the Psalm," for chorus and orchestra, appeared shortly before his death in Moscow on June 19 (N.S.; 6, O.S.), 1915.

Tanev's compositions are relatively few but finely wrought; they are much more romantically beautiful than might have been expected of a composer who disliked all 19th-century music except that of Tchaikovsky (some of whose works he completed) and who regarded counterpoint as a branch of mathematics, reserving his highest admiration for Renaissance composers Okeghem and Josquin Després, Lassus, and Palestrina. Tanev was a great teacher and a great "character," a popular eccentric and a lifelong bachelor who for many years attracted without reciprocating the passionate love of the Countess Tolstoy. (G. Ab.)

**TANEY, ROGER BROOKE** (1777-1864), fifth chief justice of the United States, whose decision in the Dred Scott case in 1857 became a centre of violent controversy, was born March 17, 1777, in Calvert County, Md. His father was a member of a family of planters, and he inherited the conservative tradition of the landed aristocracy of the South. His education in rural schools was supplemented by a family tutor and by three years of instruction at Dickinson College, from which he graduated in 1795. Since as a second son Taney would not inherit the family plantation, he was trained for a legal and political career. He studied law at Annapolis under Judge Jeremiah T. Chase of the Maryland General Court and was admitted to the bar in 1799.

**Early Career.**—In 1801 Taney settled in Frederick, Md., where he established himself as an able lawyer, achieved a position of prominence in political affairs, and raised a family. His marriage in 1806 to Anne Key, sister of Francis Scott Key, was a happy one and resulted in six daughters. Although his practice was demanding and his health frail, Taney found time for political activity, serving several terms in the Maryland legislature and gradually working his way into the leadership of the Federalist Party in the state.

When the War of 1812 split the Federalist Party (*q.v.*), Taney, a representative of inland agrarian interests, became the leader of the group, derisively referred to as "Coodies," which supported

the conduct of the war. Although the former Federalists cooperated after the war on certain matters of state politics, the breakdown of the Federalist organization left Taney without party affiliation. In the 1820s he aligned himself with Andrew Jackson and thereafter was found in the ranks of the Democrats. This transition was not unnatural since Jackson, like Taney, was a slaveowner and a member of the landed aristocracy, and they shared many of the same views.

In 1823 Taney moved to Baltimore, where professional opportunities were greater, and was soon recognized as a leader of the Maryland bar. His extensive practice broadened his knowledge of the law and gave him wide acquaintance with the economic developments of his time. In 1827 he was appointed attorney general of Maryland, an appointment which honoured his legal attainment while allowing him to continue his private practice.

**The Bank War.**—Taney became a national figure as a result of his participation in the bank war of the 1830s. When Jackson reorganized his cabinet in 1831, Taney accepted an appointment as attorney general. At that time the Bank of the United States, chartered by Congress in 1816, had attained a dominant position in American finance and sought to exercise its influence in order to force immediately the renewal of its charter which was to expire in 1836. Although Taney had once regarded a national bank as a desirable instrument for regulating the currency, his experience with the activities of the Bank of the United States convinced him that the bank had abused its powers. When in 1832 Congress enacted a bill to renew the charter, Taney persuaded Jackson to veto it and wrote much of Jackson's veto message.

In the ensuing presidential campaign the Bank took an active part, financing its supporters and attempting to frighten its opponents by manipulating the credit structure. The revelation of these events after Jackson's re-election in 1832 led Taney and others to advise Jackson to withdraw government deposits from the Bank of the United States and place them in selected state banks. Jackson delayed action for a number of months but eventually in 1833 ordered William J. Duane, then secretary of the treasury, to remove the deposits. When Duane refused, Jackson dismissed him and gave Taney a recess appointment as secretary of the treasury. Taney's subsequent action in removing government deposits to a number of state banks was subjected to virulent partisan attack, much of which was undeserved since the bank had engaged in political and financial activities of questionable character. Nevertheless, Taney's attempt to improve and regulate the currency through a system of state banks proved ineffective, in part because Congress failed to enact implementing legislation. Although the Bank was not rechartered, opposition to Taney and his financial program was so strong that his appointment as secretary of the treasury was rejected by the senate when it was presented for confirmation. Three years of cabinet service, during nine months of which he held a recess appointment as secretary of the treasury, thus ended, and Taney returned to private life and attempted to rebuild his law practice.

**Chief Justice.**—In 1836, at the age of 59, Taney began the last and greatest phase of his career. As a reward for his political loyalty, Jackson appointed him Chief Justice of the United States to succeed the celebrated Federalist John Marshall. Despite Whig opposition, Taney was confirmed by the Senate and took the seat he was to hold for nearly three decades (1836–64). His appointment coincided with change and expansion in the personnel of the court, with the result that by 1837 all but two of the nine

THE BETTMANN ARCHIVE

ROGER BROOKE TANEY

judges were appointees of Jackson or Van Buren. This change alarmed those who feared that property rights would be at the mercy of state legislatures. Although the Taney court did give greater scope to the exercise of state power than had the Marshall court, it was no less vigilant in maintaining federal supremacy until it foundered on the constitutional questions presented by Negro slavery.

**States' Rights.**—In his first great judicial utterance, *Charles River Bridge v. Warren Bridge*, 11 Pet. 420 (1837), Taney expressed his deeply held conviction that the powers conferred by corporate charters should be given a narrow interpretation in order to preserve the rights of the community. Speaking for a majority of the court, he rejected the claim of a bridge company that the subsequent grant by the state legislature of a charter to another bridge company impaired the obligation of contracts. The same emphasis on the rights of the community pervaded Taney's opinions dealing with the impact of the commerce clause on state regulatory legislation. He was unwilling to use the commerce clause as an instrument to defeat state regulation; e.g., *License Cases*, 5 How. 504 (1847), *Passenger Cases*, 7 How. 283 (1849), dissenting opinion. While he concurred in several opinions upholding state regulation on a police power rationale, his own view appears to have been that the states, in the absence of federal legislation, remained free to regulate commerce.

Despite his willingness to sustain state authority against constitutional attack, Taney's court cannot be characterized as interested only in "states' rights." Whenever state authorities threatened or interfered with the exertion of federal power, Taney was firm in upholding federal supremacy. His opinion in *Ableman v. Booth*, 21 How. 506 (1858), denying state power to obstruct the processes of the federal courts, remains a magnificent statement of constitutional federalism. Under Taney's leadership, federal judicial power was expanded over corporations; the admiralty jurisdiction was extended to inland waters; the federal government was held to have a paramount and exclusive authority over foreign relations; and congressional authority over U.S. property and territory was vigorously upheld.

**Dred Scott Decision.**—Until the mid-1850s the court avoided embroilment in the controversy over slavery which was constantly increasing in bitterness. As late as 1850, in *Strader v. Graham*, 10 How. 82, Taney succeeded in disposing of important constitutional questions relating to slavery on a narrow jurisdictional ground. However, by 1856 the prestige of the court was thought so great and the issue so momentous that the court was urged to settle the question whether Congress had power to restrict slavery in the territories. In the *Dred Scott* case, 19 How. 393 (1856), one of the great "self-inflicted wounds" of the Supreme Court, the court yielded to the temptation to solve this fundamental political controversy by constitutional decision. Taney, writing for a majority of the court, held that Negroes could not possess rights of citizenship entitling them to sue in federal courts; that the removal of a slave to a territory in which Congress, by the Missouri Compromise, had prohibited the holding and owning of slaves did not result in freedom because Congress lacked such power; and, finally, that the return of a Negro to a state recognizing him as a slave was conclusive as to his status. On the facts of the *Dred Scott* case, the third and narrowest ground was sufficient to dispose of the case. Taney's further holdings, that Congress had no power to exclude slavery from the territories and that Negroes could not be citizens, were disputed by vigorous dissenting opinions and were bitterly attacked by the Northern press. The decision became an issue in national politics and, with the victory of the Republicans in 1860, the prestige of the court reached the lowest point in its history. Taney's attachment for Southern culture thus resulted in an unsuccessful attempt to safeguard that culture from the legislative power of the Northern majority. (See also DRED SCOTT DECISION.)

**Final Years.**—Taney's last years were spent in futility and despair. His background led him to sympathize with the South, and he hoped that the South would be allowed to secede peacefully. During the war the court, though it continued to function as part of the government, was suspected of disloyalty. Taney, believing

that war issues might come before the court, prepared in the privacy of his study a series of opinions in which he found various war measures unconstitutional. *Ex parte Merryman*, Fed. Cases no. 9,487 (1861), containing a vigorous defense of the rights of civilians in war time, is the only one of those opinions to be found in the reports. Taney's death in Washington on Oct. 12, 1864, went largely unnoticed and unregretted.

Taney's relations with his family and his associates were warm and pleasant. Not an effective platform speaker, he was at his best in personal association, where his warmth, kindness, and quiet charm quickly resulted in intimacy. He presided over the Supreme Court with dignity and courtesy, and his personal qualities, so his colleagues have testified, led to greater unity on the court than otherwise would have occurred. His legal abilities were of the highest order, as his concise, persuasive opinions indicate. Although a devout Roman Catholic, he refused to allow members of his faith to proselytize among his wife and daughters, who with one exception were Protestants.

Any evaluation of Taney is complicated by the fact that his actions and attitudes affecting slavery and national unity are part of the tradition defeated in the Civil War. Yet his outstanding abilities had a lasting influence on the content and development of American constitutional law.

**T'ANG**, the dynasty that ruled China from A.D. 618 to 907. The first emperor Li Yuan (or Kao-tsu, 618–626) was a member of the aristocracy of part-barbarian, part-Chinese origin, that had formed the governing class in the Northern Chou state, centred on Ch'ang-an in the 6th century, as well as in the Sui dynasty (A.D. 589–618). Li Yuan's success in obtaining the throne at the end of the Sui dynasty was largely due to his second son, Li Shih-min (or T'ai-tsung, 626–649), who succeeded him.

T'ai-tsung was succeeded by his son Kao-tsung (649–683), who soon fell under the domination of one of the most remarkable women in Chinese history, Wu Tse-t'ien or Empress Wu. She became the real power in the land even during her weak husband's lifetime. After his death she deposed her two sons in succession and ruled in her own name, a thing never achieved before or since in China. She changed the dynastic name to Chou but insured the eventual restoration of T'ang when invasions of the Khitans and Turks in the northeast necessitated an appeal to the people's loyalty.

During the reign of Kao-tsung the T'ang empire completed, at great cost, the conquest of northern Korea. But after c. 682 the northern Turks revolted, following 50 years of submission, and the Four Garrisons in Sinkiang were lost to the Tibetans. Also the Korean conquests were swallowed up by T'ang's erstwhile ally, the southern Korean state of Silla, which united the peninsula for the first time.

The aged empress's forced abdication in 705 was followed by an unstable period during which her two sons, Chung-tsung (705–710) and Jui-tsung (710–712), followed one another on the throne but were dominated by cliques centred around the empress of the former, surnamed Wei, and their sister, the T'ai-p'ing Princess. Successive *coups d'état* finally led to Jui-tsung's abdication in favour of his son, known as Ming Huang the Brilliant Emperor (alias Hsuan-tsung, 712–756). His reign, the longest in the dynasty, was also its high point of prosperity. With the help of able ministers he corrected administrative abuses that had grown up in the previous decade but efforts at fiscal reform, mainly carried out by special commissioners of aristocratic background, conflicted with the interests of the rising new landowning class. A political struggle ensued which resulted in the virtual dictatorship of the imperial kinsman Li Lin-fu, from 736 onward, after which the emperor withdrew into a life of pleasure.

Under Ming Huang the Chinese once more expanded on all

fronts but at the cost of establishing large standing armies composed to a dangerous extent of non-Chinese troops. In the years 751–754 the Chinese suffered defeats in Manchuria; at the battle of Talas against the Arabs in central Asia; and especially against the state of Nan Chao in Yunnan. Real disaster struck in 755 with the revolt of the commander of the northeast sector of the frontier. This was An Lu-shan, of part-Sogdian and part-Turkish origin, who owed his promotion, like the barbarian generals in other sectors, to Li Lin-fu's fear of Chinese rivals.

The rebels captured the capital and drove the emperor to flight. The crown prince (Su-tsung, 756–762), who assumed the throne in the northwest succeeded, with the aid of a contingent of Uighur troops, in recapturing Ch'ang-an and Lo-yang. But the T'ang forces lacked strength to complete their victory and the war dragged on inconclusively until 762 when the last rebel pretender was killed. The northeastern provinces remained in control of former rebel generals who were acknowledged as T'ang governors; much of the rest of the country was in the hands of military leaders who were often as insubordinate as the former rebels. In the west the Tibetans, now at the height of their power, occupied large areas and in 763 they even briefly occupied Ch'ang-an. In the north, T'ang's allies, the Uighurs, were almost as oppressive as the Tibetans. The disruption of government by the rebellion led the emperors to place increasing reliance on their personal attendants, the palace eunuchs, who were given control of the palace armies.

During the reigns of Tai-tsung (762–779) and Te-tsung (779–805) the policy of the T'ang court was mainly a negative one of trying to control the militarists by diplomacy while the country slowly recovered from the effects of war. During the brief interlude of Shun-tsung's reign in 805 a reform party tried unsuccessfully to take the palace armies out of the hands of the eunuchs, who thereafter controlled the person of the sovereign, setting up and removing emperors as they pleased.

Under Hsien-tsung (805–820) some success was achieved in asserting central authority over the provinces but it was not lasting, and the northeast remained effectively autonomous to the end of the dynasty.

Hsien-tsung was murdered by eunuchs and the short reigns of Mu-tsung (820–824) and Ching-tsung (824–827) followed. Wen-tsung (827–840) plotted with his ministers to deprive the eunuchs of their military power but the plan misfired and resulted in the Sweet Dew incident of 833 in which three chief ministers and many other officials were slaughtered. Under Wu-tsung (840–846) the simultaneous decline of the Tibetan and Uighur empires eased the pressure on the northern and western frontiers. This was followed by the persecution of the Manichaean church in China, which had enjoyed Uighur protection, and this in turn led on to an unparalleled suppression of Buddhist monasteries and laicization of monks and nuns, a blow from which Chinese Buddhism never fully recovered.

The reign of Hsuan-tsung (846–859) was outwardly calm except for wars with Nan Chao in the south, but the demoralization of the central government and the lawlessness of the provinces, armies and their leaders made the dynasty quite incapable of dealing with the disturbances, provoked to a large extent by maladministration and corruption, which broke out in an ever-rising crescendo under I-tsung (859–873) and Hsi-tsung (873–888). In 875 began the great peasant uprising known as the Huang Chao rebellion, led by former salt smugglers. After roaming up and down the country for years the rebels occupied Ch'ang-an in 881. They were unable to organize the food supply of the capital and this, together with the intervention of Sha-t'o Turks, forced Huang Ch'ao to flee east in 883, where he was caught and killed.

From then on, while lawless bands terrorized the countryside, the T'ang court could only survive by playing off one military governor against another. In 903 Chu Ch'üan-chung, one of Huang Ch'ao's officers who had surrendered opportunely and obtained the governorship of the strategic region of K'ai-feng, gained control of the person of the T'ang emperor Chao-tsung (888–904). He settled the eunuch problem by a wholesale massacre. After his men had murdered Chao-tsung in 904 he placed on the throne a boy of thirteen (Chao-hsuan-ti), who was presently put through the

motions of abdication. Chu Ch'uan-chung ruled over part of north China as T'ai-tsu of Later Liang (907-915). China fell apart into a number of independent kingdoms, and unity was not restored until after the founding of Sung (q.v.) in 906. (See also CHINA: History.)

**Social and Economic Life.**—During T'ang the economic centre of gravity of China shifted from the Yellow River plain to the Yangtze. The population of the latter region increased enormously, swollen by influxes of refugees from the north, especially after the rebellion of An Lu-shan. The canal system built by Yang-ti of Sui became the lifeline of the capital, especially after the efficiency of the transport system had been improved in the reign of Ming Huang and again under Tai-tsung. Trade, both internal and external, was stimulated by the unification of the country and its far-flung conquests. Much of this trade was in the hands of foreigners, particularly Iranians, who settled in large communities in the major cities. They came both by land through central Asia and by sea to Canton. Especially during the first half of the dynasty China was very receptive to foreign ideas. Foreign music and dancing were popular, and foreign types are common among the familiar T'ang pottery figurines.

Migration and economic development led to a breakdown in the system of state registration of population and distribution of land and to the growth of private estates. After the An Lu-shan rebellion the old system was finally abandoned and direct taxation was based on actual land under cultivation and on an assessment of the wealth of the household. The salt monopoly, introduced as an emergency war measure during the rebellion, became a major source of government revenue and continued into the 20th century. The increase in trade led to a need for coinage; as the government mints were unable to produce an adequate supply, counterfeiting was a chronic problem. The shortage of cash and the difficulty of transporting the bulky copper coins encouraged the development of credit instruments such as the so-called "flying money," a kind of bank draft. True paper money did not appear until the 10th century.

Society remained decidedly aristocratic but economic expansion led to the creation of a more broadly based landowning class. These new men began to push their way into the government by means of the examination system, which, although a development from earlier institutions, really began in Sui and T'ang. Empress Wu, especially, used it to undermine the position of the aristocratic clans. The competition between aristocratic privilege and the ideal of selection by merit continued throughout the dynasty.

**Religion and the Arts.**—The T'ang emperors officially supported Taoism because of their claim to be descended from Lao-tzu, but Buddhism continued to enjoy great favour through most of the period, especially under Empress Wu. The famous pilgrim, Hsuan-tsang, who went to India in 629 and returned in 645, was the most learned of Chinese monks and introduced new standards of exactness in his many translations from Sanskrit. In spite of such direct Indian influences through Indian teachers in China as well as Chinese pilgrims to India, the most significant development in T'ang was the growth of new indigenous schools which adapted Buddhism to Chinese ways of thinking. Most prominent were the syncretic T'ien-t'ai school which sought to embrace all other schools in a single hierarchical system, even reaching out to include Confucianism as well, and the radically antitextual, antimetaphysical Southern Ch'an (Zen) school which had strong roots in Taoism. The popular preaching of the salvationist Pure Land sect was also important. After the rebellion of An Lu-shan a nationalistic movement in favour of Confucianism appeared, merging with the efforts of T'ien-t'ai Buddhism to graft Buddhist metaphysics on to classical doctrine and lay the groundwork for the Neo-Confucianism of Sung.

In literature the greatest glory of the T'ang period was its poetry. By the 8th century poets had broken away from the artificial diction and matter of the court poetry of the Southern Dynasties and achieved a new directness and naturalism. The great flowering came in the reign of Ming Huang, the time of the great figures of Li Po (701-762), Wang Wei (698-759) and Tu Fu (713-770), besides a host of lesser names. The rebellion of An

Lu-shan and his own bitter experiences in it brought a new note of social awareness into the later poetry of Tu Fu. This appears again in the work of Po Chü-i (772-846), who wrote verse in clear and simple language. Toward the end of the dynasty a new poetic form, the *ts'u*, in a less regular metre than the five-word and seven-word *shih*, and meant to be sung, made its appearance. The *ku-wen* or "ancient style" movement grew up after the rebellion of An Lu-shan, seeking to replace the euphuistic "parallel prose" then dominant. It was closely associated with the movement for a Confucian revival. The most prominent figures in it were Han Yü (768-824) and Liu Tsung-yuan (773-819). At the same time came the first serious attempts to write fiction, the so-called *ch'uan-ch'i* or "tales of marvels." Many of these T'ang stories later provided themes for the Chinese drama.

The patronage of the T'ang emperors and the general wealth and prosperity of the period encouraged the development of the visual arts. Though few T'ang buildings remain standing, contemporary descriptions give some idea of the magnificence of T'ang palaces and religious edifices and the houses of the wealthy. Buddhist sculpture shows a greater naturalism than in the previous period but there is some loss of spirituality. Few genuine originals survive to show the work of T'ang master painters such as Wu Tao-hsuan (c. 700-760) who worked at Ming-huang's court. As a landscape painter the poet Wang Wei was a forerunner of the *wen-jen* or "literary man's" school of mystical nature painting of later times. The minor arts of T'ang, ceramics, metalwork, textiles, etc., give expression to the colour and vitality of the life of the period. Printing appeared for the first time during T'ang. Apparently invented to multiply Buddhist scriptures, it was being used, by the end of the dynasty, for such things as calendars, almanacs and dictionaries. The first printing of the Confucian classics came after the end of the dynasty in 932 in Szechwan.

**TANGANYIKA, LAKE**, in East Africa, is the longest freshwater lake in the world (420 mi. [676 km.]) and the second deepest (4,708 ft. [1,435 km.]), but is comparatively narrow, varying in width from 30 to 45 mi. (48 to 72 km.). It covers about 12,700 sq.mi. (32,893 sq.km.) and forms the boundary between Tanganyika (Tanzania) and the Democratic Republic of the Congo. It occupies the southern end of the western arm of the Great Rift Valley, and for most of its length the land rises steeply from its shores. Although drinkable, its waters tend to be brackish.

The lake was first visited in 1858 by R. F. Burton and J. H. Speke, who reached Ujiji, the place where in 1871 H. M. Stanley "found" David Livingstone. The southern half was first circumnavigated by V. L. Cameron in 1874, when the Lukuga outlet was discovered, and the whole lake was surveyed by Stanley in 1876.

Though fed by a number of rivers, the lake is not the centre of an extensive drainage area. The largest river is the Malagarasi, which rises to the north of Kigoma and arcs eastward before discharging into the lake only about 50 mi. (80 km.) due south of its source. Others are the Ruzizi, which carries the overflow from Lake Kivu, and the Kalambo, having one of the highest waterfalls in the world (over 700 ft.; 213 m.).

The lake is situated on the dividing line between the floral regions of East and West Africa, and the oil palm, so characteristic of the latter, is found on its shores. Rice and subsistence crops are grown along the shores, and fishing is also of some significance. Hippopotamuses and crocodiles abound in the waters of the lake, and in places the rare West African sharp-snouted crocodile, *Crocodylus cataphractus*, occurs. The bird life is varied because of the lake's situation between the East and West African regions. The mountains north and south of Kigoma are the only places in Tanganyika where the chimpanzee is found.

There had been considerable traffic across the lake before the arrival of the European, but this had nearly all been from west to east, so that many of the numerous tribes now living on its eastern borders trace their origins to areas in the Congo. They

are predominantly Bantu, with traces of Hamitic (Tusi) influence in the north and of Ngoni in the south. The areas of both sides of the lake suffered heavily from the depredations of slave traders.

The chief towns on the lake are Bujumbura (Burundi); Uvira and Albertville (Democratic Republic of the Congo); Kigoma, Ujiji, Karema, Mtakuja, and Kipili (Tanzania); and Mpulungu (Zambia). Steamers traverse the length of the lake in about four days, although navigation is impeded somewhat during the dry season by strong, shifty winds.

**BIBLIOGRAPHY.**—Accounts of the discovery and early exploration of Lake Tanganyika are to be found in the works of such explorers as Sir Richard Francis Burton, David Livingstone, V. L. Cameron, H. M. Stanley, E. C. Hore, and J. Thomson. (J. P. Mr.; X.)

**TANGERINE**, a small thin-skinned variety of orange with a deep reddish-orange peel belonging to the mandarin orange species (*Citrus reticulata*). See ORANGE.

**TANGIER**, a port and chief town of the province of the same name in northern Morocco, lies on the Strait of Gibraltar, in a bay sheltered from the west wind by Tangier Point, and 36 mi. (58 km.) SW of Gibraltar. Pop. (1960) 141,714. With its surrounding suburbs, Tangier was an international zone from 1923 to 1956. In 1962 it became the summer royal residence.

The town is built on the slopes of a chalky limestone hill. The old town (medina), enclosed by the 15th-century Portuguese ramparts, descends toward the harbour; it is dominated on the northwest by a *kasbah* and the ancient sultan's palace (now a museum), and on the southeast by the Great Mosque. It is crossed by the Rue es Siaghine (des Siaghines), a busy street of money changers, jewelers, and banks, which runs from the Petit Socco (*souk*) to the Grand Socco at the southwestern gate of the medina, beyond which stretches the modern town. The Muslim population have quarters in the north of the medina, and the Jews and some Europeans are dispersed around the centre and the south. Newly built European quarters (mainly French) were developed south of Tangier, and others to the west on the Marchan Plateau and "the Mountain," where the houses are scattered among gardens.

Tangier developed into an important trade centre after it became an international zone (see *History*). Its prosperity resulted from its being a free money market. Although its trade declined during World War II, it continued to benefit from its special economic and financial status until 1960, when this status was abrogated, and it became a free port in 1962. The town has little industry except that of the building trades and tourism; there is some fishing. It is connected by rail and road with Fès, Meknès, Rabat, and Casablanca. There are regular shipping services to Europe via Gibraltar. The international airport at Bouhaff-Souahel lies 8 mi. (13 km.) S.

TANGIER PROVINCE stretches southeastward to the Er Rif Range. Area 141 sq.mi. (365 sq.km.). Pop. (1960) 164,246, of which two-thirds were Muslim; more than 40,000 Europeans, three-fourths

of whom were Spanish; and about 15,000 Jews, mainly shopkeepers and merchants. The agricultural resources are low; the province produces vegetables only, though poultry breeding is a main occupation. (J.-J. Ds.)

## HISTORY

Few cities have had a more varied history than Tangier. Existing already in the 15th century B.C. as a Phoenician trading post, it later became Carthaginian, and the remains of a Carthaginian settlement are still to be seen near Cape Spartel. In 81 B.C. the Roman general Quintus Sertorius captured the city, then known as Tingis; it had previously belonged to the Mauretanian king Bocchus, a partisan of L. Cornelius Sulla in the Roman civil strife of the moment. In 38 B.C. it was taken on behalf of Octavian by a later King Bocchus from his brother King Bogud, who supported Mark Antony. Becoming a free city, in A.D. 42 it was made the capital of the Roman province of Mauretania Tingitana, with the name Tingis Colonia Julia Traducta; it remained important commercially after the political capital was removed to Volubilis.

After five centuries of Roman rule and a brief occupation by the Vandals, Tingis was captured by the Byzantines. When the Arabs arrived in the 7th century, however, Ceuta and not Tangier seems to have been their principal fortress. Uqba (Okba) ibn Nafi reached Tangier in 682 and from there raided deep into Morocco. In 707, when Musa ibn Nusayr was appointed governor of North Africa, he had to reconquer Tangier; the Berber Tark ibn Ziyad was appointed as governor and in 711 raided Spain. In 951 Abdurrahman III of Córdoba annexed the city, and it remained under Muslim Spanish rule till the collapse of the Córdoba caliphate about 80 years later. Under the Almoravids Tangier became Moroccan again and remained so till captured by the Portuguese in 1471. In 1580 it passed, with Portugal itself, to Spain, returning to independent Portugal in 1656. In 1662 it was transferred to the English crown as part of the dowry of Catherine of Braganza. Great hopes were put on this new English possession; but though a fine mole was built and new fortifications erected, the expense of maintaining the city against Moroccan attacks, and the difficulties caused by Protestant suspicions of it as a centre of Catholicism, caused it to be abandoned again in 1684. Since then it has remained a portion of the Moroccan Empire.

**The 18th and 19th Centuries.**—Tangier began to play a significant role in history again at the end of the 18th and the beginning of the 19th century. At the end of the 18th century there was a British consul and over 100 British subjects there and in Tetuan. During the great siege of Gibraltar by the Spanish (1779-83), these were expelled by the sultan. During the 19th century Tangier became the diplomatic capital of Morocco. In 1840 the European consuls acting on behalf of the sultan were entrusted with forming a commission to supervise matters affecting public

health in the city. This was the origin of the later Hygiene Commission; from 1893 this dealt not only with sanitation but also with the quarantine of shipping and pilgrims, the inspection of markets, street lighting, and fishing rights. The year 1844 marked the beginning of Sir John Drummond Hay's period of service as British representative in Morocco (1844-85); this was a period when British trade and political influence predominated.

In 1844 Tangier was bombarded by a French fleet as part of the French campaigns against Abd-el-Kader (q.v.) in Algeria. When the Spanish invaded Morocco in 1860, British policy which was directed to preventing any continental power from se-

(LEFT) MARKET SCENE IN TANGIER. (RIGHT) THE BAY OF TANGIER SEEN FROM THE SULTAN'S PALACE IN THE WALLED CITADEL, OR KASBAH

curing control of the southern shore of the straits, led to the issue of a British warning that Britain would not permit a permanent Spanish occupation of Tangier or of the nearby Moroccan coast. About the same period, various foreign powers began to establish their own postal services. In 1857 the British Consulate General at Tangier opened a receiving agency for the Gibraltar Post Office; the Spanish followed suit in 1861, and the French about the same date. Just before World War I, the Germans also opened a Post Office, but it did not survive the war. On the establishment of the French protectorate in Morocco in 1912 the French Post Office was amalgamated with the Sharifian; but the British and Spanish Post Offices survived till after the end of the international regime in 1956. In 1864 a lighthouse was established at Cape Sparte; its neutrality was guaranteed by the sultan, but its maintenance was entrusted to the consuls.

**International Status.**—The result of these privileges was that Tangier received an international regime of its own when the rest of the country became a protectorate. Already in the proposed Franco-Spanish Agreement of 1902, the two powers declared themselves willing to see the eventual neutralization of the city; in the Anglo-French Agreement of 1904 it was laid down that Tangier should have a special status. This was confirmed at the Algeiras Conference (1906). With the establishment of the protectorate in 1912, a commission with French, Spanish, and British members was appointed; by 1914 it had with difficulty agreed on certain recommendations. Then came World War I; this necessitated fresh discussions so that a statute was not agreed upon until 1923. Five years later further modifications were introduced, Great Britain, France, Spain, the Netherlands, Belgium, Sweden, Portugal, and Italy being finally recognized as the administering powers. This statute remained operative until June 14, 1940, when Spain took advantage of the fall of France to occupy the zone in the name of the khalifa of Tetuan and to introduce a Spanish regime. After the war the victorious allies insisted on Spanish withdrawal, and on Oct. 11, 1945, the International Administration was reestablished, with the participation of the United States. Italy was readmitted later. An invitation was issued to the Soviet government, which, however, refused to come in so long as Franco's government took part. With some minor modifications the statute then remained in force until the independence of Morocco (1956).

**Administration Under the International Regime.**—During the international regime the representatives of the powers (with the exception of the U.S. minister) were no longer accredited to the sultan but occupied themselves with the administration of the city. Authority was vested in a Council of Control composed of the consuls general of the administering powers. Beneath this, there was a Legislative Assembly in which the European powers and the Moroccans were represented in fixed proportions (which were periodically adjusted to meet new conditions) and selected by such means as each government concerned thought fit. The sultan was represented by a *mendub*, who was in fact a nominee of the French authorities. The customs were manned by French officials. French influence was strong in the political and educational spheres. Economically and by population, however, the city, in so far as it was European, was predominantly Spanish, owing to the proximity of Spain, the presence of 17,000 Spanish residents, and the fact that it was surrounded by the Spanish-administered zone. The police were Moroccans under the command of French and Spanish officers with a Belgian commandant. Mixed courts administered justice. For many years the chief administrator was French; after World War II the post was reserved to members of smaller powers, such as the Netherlands or Portugal.

The international administration was often severely criticized for concerning itself chiefly with the balance of interest of the various European powers, particularly France and Spain, rather than with the welfare of the majority of the inhabitants. Certainly very little was done, except by private initiative, for the education, health, or labour conditions of the Moroccan population. Nevertheless, thanks to the security, the free money market, and the tourist attractions of the site, Tangier grew from a small

seaport to a fine city of about 142,000, becoming an important residential and tourist centre, as well as a pole of attraction for adventurers of various types. It acquired an excellent port, and road and rail connections with the rest of the country.

**Integration with Morocco.**—After the recognition of Morocco's independence in 1956, the Moroccan members of Tangier's Legislative Assembly demanded that Tangier be integrated with Morocco. The powers concerned did not object, and on July 5, 1956, an interim agreement was reached (in the form of a protocol) for the transfer of control. On July 8 a Moroccan governor was appointed, and on Oct. 29, 1956, the Declaration of Fedala, signed by representatives of the powers concerned, finally abolished the statute and sanctioned the complete integration of Tangier into the rest of Morocco. A Royal Charter issued on Aug. 30, 1957, confirmed the special economic and financial status of Tangier as a free money market, subject to termination after six months' notice; such notice was in fact given in June 1959. In January 1962 a free zone was created in the port.

**BIBLIOGRAPHY.**—Rom Landau, *Portrait of Tangier* (1952); E. M. G. Routh, *Tangier: England's Lost Atlantic Outpost* (1912); G. H. Stuart, *The International City of Tangier*, 2nd ed. (1955). (N. B.A.)

**TANIMBAR ISLANDS** (TIMORLAUT ISLANDS), a group of islands in the Malay Archipelago, southwest of the Aru Islands, between 6°20' and 8°30' S and 130°40' and 132°5' E. Politically, the islands belong to the Republic of Indonesia. They form part of the outermost alpine arc, which includes Timor and the Ewab Islands and recurves westward through Ceram (Seram) and Buru. The group lies outside the zone of the recent volcanic activity. There are about 30 islands, the largest being Jamdena, 70 mi. (113 km.) long and 28 mi. (45 km.) wide. Thickly wooded hills extend along the east coast; the west coast is lower where, opposite the island of Sera, a gulf extends far inland. In places there are precipitous cliffs, and a narrow foreshore is fringed with coconut palms and mangrove. There are many small islands off the western coast of Jamdena; off the northeastern coast is Larat, with a rocky coast and high cliffs and with thick vegetation along the foreshore. Off the southwestern coast is Selaru, which is 32 mi. (51 km.) long, rather flat, and has much grassland.

Though there are extensive swamps on many of the islands, there are practically no rivers, with a resulting lack of fresh water. The soil supports maize (corn), rice (in small stretches), coconut and sago palms, yams, plantains, mangoes, and papayas. The slight depth of soil prevents trees from attaining great height.

The vegetation includes sterculias and fig trees, leguminous trees and shrubs, myrtles, the scarlet hibiscus, pandanus, palms, a species of breadfruit tree, rare and lovely orchids of many kinds, crotons, dracaenas, and many varieties of ferns. The animal life shows Australian affinities and comprises wild buffalo, wild pig, the cuscus, flying fox, many snakes, lizards, and frogs. The birds include the scarlet lory, honey eater, ground thrush, and oriole. Butterflies are numerous and include *Papilio aberram*, and among the beetles is a gorgeous golden-coloured buprestid (*Cyphogastra splendens*).

The islands form part of the Maluku Tenggara (Southeast Moluccas) *kabupaten* (regency) in the province of the Moluccas. The capital of Jamdena is Saumlakki, at the southwestern end of the island, and of Larat, the town of the same name, on a narrow strait opposite Jamdena.

Though the Tanimbar group was discovered by the Dutch in 1629 and claimed by them in 1639 by right of discovery, Dutch rule was not established until about 1900. The isles were also visited by Capt. Owen Stanley in 1839 and became known to Banda traders in 1877.

The population in 1965 was approximately 50,000. The people are basically Oceanic Negroes of the Papuan variety, but there has been much mixture with Mongoloid strains, first of the Indonesian type and later, especially around the coast, with Malays. There are many pagans and a few Muslims. Christianity made some headway, and under Dutch rule cannibalism, piracy, slavery, headhunting, and intertribal fighting were suppressed. The men sometimes dye their hair a golden colour, and tattooing is known. Traces of totemism and of an age-group system survive. The

houses of wood and *atap*, sometimes built in closely packed settlements, generally on piles and entered from underneath, have carved pillars and show much artistry of construction. The men are skilful boatbuilders, use the spear and bow and arrow (with which they are adept in shooting fish), hunt, search for trepang and turtle shell, keep pigs, and work in iron, copper, and gold. The women cultivate the fields after the men have prepared the ground, weave and dye sarongs, and plait.

**TANIS** (biblical ZOAN), an ancient city in the Delta of Egypt, the capital of the 14th nome of Lower Egypt and, at one time, of the whole country; the ancient name, Djane, survives in the modern village San al Hajar ("San of the Stones"). Here, a few miles south of Lake Menzaleh (Manzilah), a huge mound of buried ruins rises from the salty flats caused by past erosion of the coast and invasion by the sea. The city owed its importance largely to its position as one of the nearest ports to the Asiatic seaboard, on the bridge between Asia and Africa.

The history of Tanis is imperfectly known. During 1884–85 Flinders Petrie found blocks of Pepi I (6th dynasty), and Pierre Montet also found blocks of Old Kingdom date, but many scholars suppose that these were removed from other sites, perhaps by Ramses II when he enlarged and beautified the city, or by some other pharaoh in search of easily quarried building stone. Among statues unearthed there were remarkable sphinxes in black granite found by Auguste Mariette in 1860 and once attributed to the Hyksos but now known to represent a 12th-dynasty pharaoh.

When the Hyksos (Shepherd Kings; see EGYPT: History) established their rule in Egypt c. 1720 B.C., their main stronghold was Avaris and their chief god Set (Setekh). Set was later the patron of San, judging by the monuments, and some think that Avaris (in Egyptian *Het-waret*, perhaps "the Castle on the Dunes") was in fact the earlier name of Tanis. The further identification with Pi-Ramesse or Per-Ramessu, the residence city of Ramses II, is even less certain, but the many colossal statues and blocks found in San bearing the name of Ramses II make it reasonable to suppose that Tanis was important in his reign.

About 1085 B.C. the 21st-dynasty pharaohs began their rule in the Delta. Tanis was their capital, and here in the precinct of the great temple they and at least some of their successors were interred. The tombs of Psusennes I and Amenemope, second and fourth kings of the 21st dynasty, and of Osorkon II and Sheshonk III of the 22nd were discovered by Pierre Montet; their silver coffins and stone sarcophagi, jewelry, and vessels are now in the Cairo Museum. The decline of Tanis was gradual but was accelerated by the rise of Pelusium, 20 mi. (32 km.) to the east, as a frontier city and entrepôt of trade.

**TANIZAKI JUNICHIRO** (1886–1965), Japanese writer who, with Akutagawa Ryūnosuke (*q.v.*), was a prominent figure in Japanese literature in the years after World War I, was born in Tokyo on July 24, 1886. His career seems on the surface to have been one of violent change, from a complete rejection of Japanese tradition in his youth to an equally strong traditionalism in his middle years and after. Yet a single theme can be traced through the whole of his work: the quest for an ideal woman, symbol of an indispensable something that has been lost.

Tanizaki's earliest short stories, the first of which appeared in 1900, have affinities with Poe. They tend to be overwrought, and Tanizaki would probably not be thought an important writer had his career ended with its first, strongly pro-Western phase. After the great Tokyo earthquake of 1923, however, he moved to the more traditional Ōsaka region, which awakened him to traditional Japanese values. *Some Prefer Nettles* (1929), perhaps his finest novel, tells of marital unhappiness that is in fact a conflict between the new and the old. The implication is that the old will win.

During the 1930s Tanizaki produced a number of discursive lyrical works, part fiction and part essay, a return to the prose

of the Heian period. The best of them is probably "The Story of Shunkin" (1933). He also undertook a rendition into modern Japanese of the greatest of Heian literary works, Lady Murasaki's *Tale of Genji*. During World War II, he occupied himself with *The Makioka Sisters* (published 1946–48), an affectionate, infinitely detailed evocation of prewar Ōsaka life. His writing after the war resembled the lyrical works of the '30s, with a strong mixture of eroticism that suggested a return to his youth. He died in Yugawara on July 30, 1965.

English translations of some of Tanizaki's works are available: *Some Prefer Nettles* (1955) and *The Makioka Sisters* (1957), both translated by Edward G. Seidensticker; and *The Key* (1961), *Seven Japanese Tales* (1963), including "The Story of Shunkin," and *The Diary of a Mad Old Man* (1965), all translated by Howard Hibbett.

(E. G. SE.)

**TANK**, a heavily armoured, self-propelled combat vehicle embodying the basic military characteristics of firepower, mobility and crew protection. They are designed for many different purposes and may be used as part of large infantry units, as a separate striking force (such as an armoured division) or for reconnaissance. (For tactics and organization, see ARMoured FORCES.)

### PREDECESSORS

The modern military tank is a direct outgrowth of World War I, but the idea underlying its development—protected, mobile striking power—had been used throughout the history of warfare. Many ancient peoples made use of war chariots to carry an attack to an enemy with speed and with some degree of protection. The armoured elephants of Hannibal and Kublai Khan were variations of the same idea. In the 15th century Leonardo da Vinci envisioned his covered chariots as a means of destroying the artillery just then being introduced to warfare. From time to time similar suggestions were advanced and occasionally devices of this kind were used in war. However, there is no evidence that such great military leaders as Condé, Turenne, Frederick the Great or Napoleon made any effort to revive the idea.

The invention of the "footed wheel" by R. L. Edgeworth in 1770 led to Thomas German's invention in 1801 of the jointed track. Neither of these was of any significance until a suitable engine was developed. Gottlieb Daimler's patent in 1886 of the high-speed internal-combustion engine opened the way for the first really practical self-propelled fighting vehicles. While interest in track-laying vehicles and improvements in their design continued in Britain and the United States during this period, the perfection of a reasonably efficient internal-combustion engine stimulated experiments with various types of armoured cars. F. R. Simms of Britain is credited with building in 1898 the first motor vehicle designed for combat purposes; it was a light four-wheeled motorcycle with an armoured shield and mounting a Maxim machine gun.

In the same year a U.S. army officer, R. P. Davidson, designed a three-wheeled automobile similarly armed and armoured. Davidson experimented also with steam-driven combat cars, as did the Russian engineer Lutski. Armoured steam-driven Fowler tractors with armoured trailers in train were used during the South African War in 1900 as supply vehicles and personnel carriers. Davidson's cars were followed in rapid succession by the Charron car in France in 1901 and the Simms war cars in Great Britain in 1902. The first turreted armoured cars were built by the firm of Charron, Girardot et Voight in France in 1904 and purchased by Russia. These were followed by the Austro-Daimler cars in Austria-Hungary, which were the first four-wheel-drive automobiles. Several other British, French, Swiss and German cars appeared. Among them was the Armstrongs-Whitworth car designed by Walter G. Wilson, who later was prominent in design and production of British tanks during World War I. During this period the track-laying vehicle, as developed by Benjamin Holt, C. L. Best and others, was being adapted for farm machinery in the U.S. During the years immediately prior to World War I, tacticians of the major powers which were to engage in that struggle did not seem to envision the part such a combat vehicle could play.

Lieut. Fleicz of the French army and Capt. (later Gen.) J. F. C. Fuller (*q.v.*) of the British army, as late as 1913 and 1914, respectively, predicted the machine gun would bring about static trench warfare, and suggested greater emphasis on means for overcoming it. But it was not until the soundness of their ideas was clearly demonstrated along the Aisne in 1914 that serious attention was given to armoured, trench-spanning vehicles.

### WORLD WAR I TANKS

The French, Belgians and Russians were quick to improvise armoured cars (*q.v.*) for fighting delaying actions against German advance cavalry. The tactics were informal but aggressive, depending on whatever the individual car commander decided. Winston Churchill, then first lord of the admiralty, quickly saw the natural affinity between aircraft and armoured vehicles. As a result, the royal naval air service under Capt. Murray Sueter improvised armoured car squadrons for protecting advanced air bases and rescuing pilots who crashed or were forced to bail out in enemy territory.

The war soon settled down to a practically continuous front because artillery and the machine gun dominated the battlefield. (See **TACTICS** and **WORLD WAR I**.) There were no flanks. With position defense and frontal attacks the only basic tactics available to either side, defense became superior to offense. Even when salients developed which permitted a form of envelopment, the attacker's own flanks became exposed and attacks eventually ground to a standstill, with casualties reaching staggering proportions. The tremendous artillery fire preparation frequently destroyed the attacker's ability to sustain his own advance because his artillery could not be moved forward over the ground it had helped to make impassable.

**British Tanks.**—In Oct. 1914, Col. (later Gen.) Sir Ernest Swinton, having seen some American Holt caterpillar tractors used as heavy artillery tractors behind the lines, was struck with the desirability of arming and armouring such vehicles as an antidote to the German machine gun. He suggested the idea to the authorities but Churchill was the only member of the committee of imperial defense who was in favour of exploring it. At the end of Feb. 1915 the war office officially abandoned the Swinton proposals but Churchill immediately created a Landships committee under the chairmanship of Eustace (later Sir Eustace) Tennyson-d'Eyncourt, a prominent naval designer.

As a result of admiralty rather than war office sponsorship, certain naval terms came into use and persisted. Parts of armoured vehicles are still known by such naval terms as hull, turret, deck, sponson, barrette, superstructure, bow, hatch and compartment.

Various experimental machines were built, ending with a large vehicle having overhead tracks, mainly the product of W. G. Wilson and Sir William Tritton. Colonel Swinton learned of these and was authorized by the commander of the British forces in France to collaborate through the war office. In June 1915 the admiralty and war office joined hands. The abortive Dardanelles landing forced Churchill's resignation in July but the committee kept interest alive in spite of army apathy. In September, primary responsibility was turned over to the war office but the Landships committee continued to function with little change except in name.

The word "tank" was coined by Swinton. Originally, for secrecy, the hull and chassis of an experimental vehicle had been made in different shops. The hull was referred to as a water carrier for Mesopotamia and was called "that tank thing" by the workmen. The chassis was described as a demonstrational chassis for the royal marines. Swinton later recalled this and it led to his suggesting the adoption

of the word "tank," which since has come into use in many languages.

The British decided to use the new tank corps to bolster a failing offensive on the Somme in spite of Swinton's arguments that it would be better to wait until more tanks were available. Out of 49 tanks, only 11 carried out the attack on Sept. 15, 1916. From then on, tanks were used in dribbles and with little effect and often under unsuitable conditions because of military and political pressure. Yet their use raised Allied and lowered German morale. Not until the battle of Cambrai in Nov. 1917 were tanks used in mass. From then on they contributed greatly to reducing the previous heavy Allied casualties. (See further **WORLD WAR I**.)

The first British tank, designated the Mark I, was produced in two types, a "male" weighing 31 tons and mounting two 6-pounders and four machine guns, and a "female" weighing 30 tons, mounting six machine guns. They were large, clumsy, and hard-riding and had limited radius, but they were well suited for trench warfare. Successive models incorporated improvements but their general appearance remained about the same throughout the war. All were about 26½ ft. long, 14 ft. wide, and 8 ft. high; they were powered first by a 105-hp. Daimler water-cooled engine and later by a Ricardo 150-hp. engine. Their speed did not exceed 4½ m.p.h. and fuel distance had reached only 24 mi. by the end of the war, while track life, because of a rigid suspension, was only about 50 mi. They could traverse obstacles 4½ ft. high, span trenches 11½ ft. wide, and climb a 22° slope. Armour thickness varied from 0.2 to 0.4 in. and was later increased to 0.47 in. In addition to combat tanks, supply, bridging, and salvage or recovery vehicles were built, sometimes by converting obsolete combat tanks.

During World War I the British also built a Medium Mark A or Whippet tank weighing 15.7 tons which carried a crew of only three men as compared with eight in the heavy tanks, and had greater speed and fuel distance than the heavy tanks. There later were a Medium B and a Medium C but these were available too late for combat.

**French Tanks.**—Though the British were the first to use tanks in battle, the French had actually preceded them in experimentation in this field. Much of this experimentation was civilian inspired. Instead of devices to defeat the German machine gun, effort initially was directed toward overcoming German barbed wire. Then, Col. (later Gen.) Eugene Estienne, like Colonel Swinton, saw an American Holt tractor, and conceived an armoured fighting vehicle. In collaboration with Eugène Brillié, a Schneider engineer who had been experimenting with small Holt tractors, the Schneider C. A. or *chat d'assaut* was successfully tested and placed in production.

Jules-Louis Breton, under-secretary of state for inventions, had been responsible for most of the earlier experiments. He succeeded in obtaining funds for proceeding with a larger vehicle designed by Col. Émile Rimailho of the St. Chamond firm and known as the *char St. Chamond*. Production was begun without consultation between the two groups. It was not until June 1916 that British developments in the new field were discovered. Premature British use of tanks on the Somme caused the French to rush pro-

BY COURTESY OF (ABOVE) U.S. SIGNAL CORPS, (RIGHT) IMPERIAL WAR MUSEUM

TANKS OF WORLD WAR I: (ABOVE) SMALL FRENCH RENAULT TANK; (RIGHT) LARGE BRITISH "MALE" MARK III

duction and the first units of *l'artillerie d'assaut* began equipping in Dec. 1916.

The first French tank attack took place in April 1917 and ended in failure. Committees bickered, and a change in high command shifted emphasis to artillery production. Nevertheless, Estienne succeeded in getting the Renault firm to design and build a light two-man tank. Another shift in high command resulted in a decision to cease building all vehicles but the Renault model. The first of these was shipped to the United States. Production was slow and it was not until the French were frightened by the German Chemin des Dames offensive that industrial production was pushed.

Although the French made many of the same mistakes as the British and there was considerable confusion over the role these new weapons of war would play, a great deal was accomplished. Jealousies existed but over-all there was less vacillation, with cancellations and reinstatements of orders, than occurred in England. The small Renault tank was armed with either a machine gun or a 37-mm. gun. The Schneider and St. Chamond tanks were armed with a 75-mm. gun and two machine guns. Their respective weights were 7½ tons, 15 tons, and 25 tons, while their crews varied from two to nine men. Unlike the British tanks, French tanks used spring suspensions that produced a better ride and increased track life somewhat.

**German Tanks.**—Though the Germans had opportunities before and during World War I to take the lead in development of the tank, they failed to do so. It was not until the capture at Cambrai (Nov. 20, 1917) of a number of British tanks that the Germans possessed any serviceable armoured vehicles of this type. The captured tanks were assembled and repaired at Charleroi, where German experts studied them, but the idea of copying them was soon abandoned. Instead, reliance was placed on a model of German design which already was well along. A few of these were delivered in time to participate in the battle of St. Quentin on March 21, 1918, and in five additional actions before the Armistice in November. The Germans also used a few captured specimens in various actions, but they never had tanks in numbers at all comparable with those of the Allies.

The German model made during 1918 was built by the Daimler company. It was designed by Joseph Vollmer and known as the A-7V. It weighed 33 tons, was powered by two Mercedes-Daimler engines of 150 hp. each, had a crew of 18 men, mounted a small cannon and six machine guns and carried thick armour, which varied from 0.59 to 1.18 in., and was designed to be proof against 37-mm. gunfire.

**U.S. Tanks.**—Before the United States entered the war, both the Holt Tractor company and the C. L. Best company had built some experimental tanks. As early as 1915, Cleve Shaffer proposed armouring and arming Fageol orchard tractors. At about the same time, E. M. Wheelock of Pioneer Tractor company and Norman Leeds of Automatic Machine company offered tank designs to the British and A. C. Hamilton of Oakland Motors built an experimental tank for the British at their request.

Committees created by Gen. John J. Pershing decided to obtain British and French tanks but interest lagged until the battle of Cambrai and the signing of the Anglo-American tank treaty to build the Mark VIII tank. With tremendous optimism, high production rates were forecast. The Mark VIII program failed partly because of the failure of the American aviation program since the same engine was to be used in both. The light tank program was equally bad. Pershing was notified in Feb. 1918 that these tanks would start arriving in France in April, yet at that time only a handful of people were working on the project and a contract had not even been let. By June it was evident that no tanks would be available and so British and French vehicles were obtained. However, U.S. troops using British tanks had to serve in the British sector. Meanwhile, a Holt gas-electric, a Holt steam tank, an Endicott and Johnson steam tank, a Pioneer skeleton, a Ford one-man and a Ford Mark I three-man tank were being tested.

Efforts were finally concentrated on the copy of the Renault known as the 6-ton tank, on the Mark VIII and on the Ford one-man tank; but the first 6-ton tanks did not arrive in France until

after the Armistice. At that time, 23,405 tanks were on order. The Ford one-man tank weighed three tons, carried a machine gun and was very cheap to produce since it used many of the standard Ford Model T passenger car components.

U.S. tank units saw action in both the British and U.S. sectors and were under the over-all command of Gen. S. D. Rockenbach. Tank training in the United States was in charge of Lieut. Col. (later General of the Army) Dwight D. Eisenhower.

## TANKS BETWEEN WORLD WARS I AND II

The plan for 1919, had the war continued, required a frontal assault by heavy tanks to achieve a breakthrough, with local exploitation by light tanks. This assault was to be followed by pouring fast medium tanks through the breaks, co-ordinated with aircraft attacks. This plan was conceived in part as a result of experiments showing that tank speeds could be considerably increased. The originator of the fast medium tank was Lieut. Col. Philip Johnson, whose first tank was designed to reach a speed of 20 m.p.h. Here was the real tactical lesson of World War I, but the victors retained only the memory of the war as it was fought with tanks and infantry in slow moving waves advancing under cover of a moving artillery barrage.

Voices were first raised in England against the accepted post-war tactics, principally by Col. (later Gen.) J. F. C. Fuller, author of the 1919 plan. He fostered the all-tank army and visualized land warfare resembling naval warfare. He was joined by Capt. B. H. Liddell Hart, who added the concepts of "tank marines"—tank-borne infantry co-operating with aircraft—and air-borne troops. They were joined by British Col. (later Gen.) G. LeQ. Martel, French Col. (later Gen.) Charles de Gaulle and German Col. (later Gen.) Heinz Guderian. However, the costs of the war and the quantities of tanks left over demanded economy, which influenced subsequent vehicle development and tactics as well.

Because track life was short, there was considerable interest in combination wheel and track tanks, several of which were designed by J. Walter Christie in the United States. But eventually, as rubber bogie tires were adopted and track life increased, these were abandoned. The increasing popularity of the civilian passenger car brought about other mechanical improvements, many of which were also translated into tank design. Speeds increased as did radius of operation or fuel distance, air-cooled and diesel engines came into use, better suspensions were devised, intercommunication systems for crew members were developed. The French produced the first welded and cast armour and Britain, in 1929, introduced short-wave radio for communication between tanks. Armament, however, remained light and seldom exceeded a 37-mm. gun or a heavy machine gun. Armour rather than armament was emphasized because it was visualized that tanks would fight infantry rather than tanks.

**United States.**—The National Defense act of 1920 eliminated the wartime tank corps and merged tanks with infantry. This action was of great influence tactically, as was peacetime economy. Interest in British tactical developments resulted in permission for the cavalry to work with "combat cars," a term coined to circumvent the law. A few experimental vehicles were developed which eventually resulted in an excellent and reliable light tank used by both infantry and cavalry, and a medium tank utilizing many light tank components was built for the infantry. Interest also was shown in the commercial Christie tanks, which could operate as wheeled vehicles by removing the tracks, but they were not considered sufficiently rugged for adoption especially since track life had reached 1,000 miles or more.

The M-2A4 light tank weighed 14 tons, had a crew of four and carried a 37-mm. gun and three machine guns. Its speed was 35 m.p.h. and its fuel distance was 100 miles. The M-2A1 medium tank weighed 23 tons and mounted a 37-mm. gun and light machine guns. The M-2A4 was of riveted construction; the M-2A1 medium tank was welded.

The German attack on Poland in 1939 caused a complete redesign of the M-2A1 medium tank and led to a large order for light tanks. Differences between infantry and cavalry finally were buried in the creation of an armoured force on July 10, 1940.

**Great Britain.**—The British royal tank corps, though its existence was in doubt for a period immediately after World War I, continued as a separate arm. A few hundred Vickers medium tanks were built, larger versions of the French Renault but embodying many improvements. Martel and Carden Lloyd tankettes, originally intended to utilize passenger car components, came into use. These vehicles were used in a series of developmental tactical organizations along the lines suggested by Fuller and Liddell Hart. Eventually there resulted four major British vehicle types: the tankette for machine gun and mortar transport, the light tank for reconnaissance, the cruiser tank for independent long range strikes and the infantry tank for close infantry co-operation.

The first group resulted in the famous Bren carrier, the second in the light Mark VI tanks—fast, lightly armoured two-man vehicles in the five-ton class. The cruiser tanks were in the 20-ton class with speeds up to 30 m.p.h. These vehicles were developments of the U.S. Christie tanks. The infantry tanks weighed about 26 tons and had thick armour. The Christie and the infantry types were armed with a 2-pounder gun and one or more machine guns.

With the beginning of the rearmament program in 1938, the royal tank corps was consolidated with British mechanized cavalry units as the royal armoured corps, and its expansion went forward concurrently with the design of additional new tanks.

**Germany.**—Germany was denied the use of tanks, aircraft and heavy artillery by the victors of World War I. Thus in later years the Germans had a distinct advantage in not being saddled with a great deal of obsolescent equipment as was the case with its former enemies. The 1919 plan was studied and modified in the light of the later writings of Fuller and Liddell Hart. Where the official British and U.S. doctrine was that tanks were to be used to exploit the advantage after an enemy line was broken, and the French doctrine was slow moving, crushing fire power, the Germans adopted the view that tanks were properly used to obtain the breakthrough itself and tactics were worked out with dummy vehicles. The mechanical details of tank design were secretly tested in the U.S.S.R. and after the Versailles treaty was abrogated, tanks were developed and openly displayed. The Germans concentrated on light and medium tanks of good design mounting slightly heavier armament than that used in other countries. Intervention in the Spanish Civil War worked out the details of German tactics and caused some modifications in design.

**France.**—The French experimented with a few tanks, and some modernization of wartime Renault tanks was undertaken after the war, but it was not until April 1926 that a new program for light, medium and heavy tanks was undertaken. Progress was slow until the Germans began to rearm in 1934. Even then, communist agitation and nationalization of war industries prevented as much progress as was intended. By 1939, nevertheless, approximately 3,000 modern tanks had been built. The French made notable progress in armour production; besides making considerable use of cast armour, they pioneered in work with welded armour. They were successful in combining thick, well-shaped armour with light suspension systems, thus holding down over-all weights. The French were among the first to use controlled differential steering, which permitted constant power to the track sprockets even when turning.

**U.S.S.R.**—The Russian automobile corps was formed late in 1914 and many foreign automobiles were armoured in Russia and used in combat even against German trenches. British and French troops sent to Russia after the Revolution were equipped with tanks. These were given to the White Russians when the troops were withdrawn and later became the first tanks in the soviet army. A few experimental vehicles were built which copied foreign designs. Later, foreign vehicles were imported, including British commercial tanks and tankettes and a U.S. Christie. With the start of the first five-year plan in 1928 the Russians began creating designs of their own.

Soviet intervention in the Spanish Civil War permitted field testing of designs, but more real experience was obtained in the war with the Japanese on the Manchurian frontier in 1938-39. The poor quality of Russian gasoline led to the adoption of diesel

engines of German origin, and German torsion bar suspensions also were incorporated into Russian tanks. The Russo-Finnish War showed shortcomings in design although existing light and very heavy vehicle production could not be shut off immediately.

The Russians began World War II with a light T-26 tank copied from the British Vickers-Armstrongs 6-ton tank, small amphibious tanks, BT tanks developed from the U.S. Christie, several medium tank varieties and a few heavy tanks. The numbers were greater than those possessed by the Germans but the quality was not good and they were poorly handled. The T-26 tank existed in two models, one with a single turret mounting a 47-mm. gun. The other had twin turrets, each mounting a machine gun. The light amphibious tanks carried machine guns. The 11-ton BT tanks were armed with a 47-mm. gun. Both T-26 and BT varieties had been used in Spain. The T-28 and T-32 were medium and heavy types with multiple turrets mounting machine guns and short cannon either of 47-mm. or 76-mm. calibre.

**Other Nations.**—Most of the smaller nations purchased tanks from other countries, principally Great Britain, France, Sweden and Czechoslovakia. The first Swedish tanks were built from parts for German LKII light tanks shipped to Sweden after World War I and assembled under the direction of Joseph Vollmer, who had designed them originally. Spain built a few tanks of local design and the Czechs produced tanks for their own use as well as for export. The Japanese for some time used tanks purchased in Britain and France. In 1928, locally designed light, medium and amphibious tanks began to appear, some used by the army and some by the navy. Japanese tanks had considerable interchangeable parts, were thinly armoured and used diesel engines.

Poland, Austria, Australia, Belgium, Hungary, Canada and Italy produced some vehicles of their own design and others under license from other countries. Italy copied the French Renault near the end of World War I and built a few heavy tanks. The light Fiat copies of the Renault continued in use after the war. Later, British Carden Lloyd tankettes were built under license and evolved into a smaller vehicle. Experience gained in Ethiopia and in Spain in 1935-36 led to the design of medium tanks, lightly armed and armoured. Both were in use at the beginning of World War II.

## WORLD WAR II

The Spanish Civil War had demonstrated the deadliness of a concentrated attack sustained in depth on a narrow front. It was the method used by the Germans in attacking Poland in 1939. Tanks and dive bombers were given the primary role in achieving deep, fast-moving penetrations. Motorized infantry followed close behind. The campaign was a brief dress rehearsal for invasion of the Low Countries and France the following year. French and British tanks outnumbered the German tanks but were widely dispersed in accordance with the French principle of close infantry support. German tactics of punching in mass on narrow fronts made the most of the opportunity and the campaign was soon over.

From France, the war moved to North Africa. There the tactics were similar to the naval tactics originally envisioned by General Fuller. When Germany attacked Russia, its previous tactics were not as successful. The Germans used 2,400 tanks against the Russians' 24,000. Within three months the Russians had lost 17,500 tanks and the Germans 550, but the areas were great and the Russians traded land for time. The Germans had made an organizational change which weakened their thrusts. In 1939 there had been 300 tanks per armoured division. To attain what Hitler believed would be greater mechanized fire power, more armoured divisions were created with fewer tanks per division, but these units lacked punch.

The British and U.S. forces copied German organization and followed this change also. The Russians learned by experience. When they resumed the offensive at Stalingrad, the Russians had more tanks and aircraft and applied successfully the tactics the Germans had used in France. Differences in tactical concepts were reflected in the designs produced by different armies—the Germans particularly tending as the war went on to build more

heavily armed and armoured monsters, sometimes at the expense of mobility and mechanical reliability. The days when strategic surprise with large masses of armour was possible for one or another opponent gave way to fierce encounters between forces more equally matched in armour. Numbers, skill and daring were still to prove decisive in many actions, but the tank design race became one essentially between projectile and armour. In this the Germans always were in the lead.

Early in the war, tanks received a great deal of publicity. They were spectacular and many people in and out of military service became conditioned to their success. Later, in certain theatres where areas for maneuver were circumscribed, people jumped to the conclusion that tanks were obsolete. Yet right up to the end of the war the issues between the Germans and Russians were largely decided by tanks and self-propelled artillery. The tank served most usefully in World War II when employed in mass on suitable occasions by commanders who fully appreciated what it could and could not do. Again, it was most effective when used as a member of an integrated team including all the other ground arms and supported by suitable aircraft.

**Germany.**—After the Germans overran Czechoslovakia, they took over production of Czech TNH tanks, calling them 38 (t). German production was fairly well centralized and between 1939 and 1942 no overtime was worked. After the United States entered the war the first real attempt at economic mobilization was made, but it was not until 1944 that Albert Speer, then chief of production, was given power to forbid design changes which would interfere with production.

Hitler, either directly or indirectly, made many engineering decisions, sometimes on obscure details. In spite of the German totalitarian government, there was much extravagance in the number of vehicle types and in design complications, in addition to the tremendous use made of modified captured vehicles. Allied bombing caused some dislocation of production but, from 1940 to 1944, German tank production increased tenfold, then it fell, but only partly due to bombing. Other factors were oil shortage, use of slave labour, transportation difficulties and extravagance in man hours due to lack of knowledge of mass production methods.

Between 1939 and 1944, Germany produced 42,932 armoured vehicles. As the war forced the Germans more and more on the defensive, the trend was toward the armoured assault gun and huge tank destroyers rather than tanks because more of the former could be produced for the same effort. The Germans began the war with tanks mounting heavier armament than those of the Allies and during the war they constantly increased these calibres. Armour was also constantly thickened, it being a principle that the armour of a tank should be proof against the weapons it carried. Although many vehicle types were produced, the best of the German tanks probably was the Panther, which was developed after encountering the Russian T-34. The German vehicle was

superior to the Russian except in mechanical reliability. The Panther had thick, well-sloped armour of welded construction. The main armament was a high velocity 75-mm. gun. This tank weighed 47 tons and had a speed of nearly 30 m.p.h. The Tiger, a heavier and somewhat slower tank, mounted an 88-mm. cannon. Late in the war, still heavier tanks mounting high velocity cannon up to 128 mm. were in use and even larger tank guns and new tanks were being tested.

**United States.**—After the German invasion of Poland, re-armament started in the U.S. but there was considerable confusion. The extent and need for arming were as vague as were the possible theatres of war should the

United States become involved. Existing mobilization plans had to be scrapped, and lend-lease added to the confusion. After Pearl Harbor on Dec. 7, 1941, the president set up production goals so great that U.S. industry was aghast but willing to try to meet them. In spite of the president's demands that heavy tanks be produced and although the heavy M-6 tank design was available, the project was canceled because the new armoured force did not want a heavy tank and preferred to use available shipping space to ship twice as many medium tanks.

There was a great deal of bad blood between army service forces and the civilian War Production board but, in spite of the conflict between them, production was prodigious. There were 287,425 combat vehicles built during the war, together with enough spare parts to have built half again as many more.

The original M-3 medium tank had a 75-mm. gun mounted on the right front of the hull with machine guns in the bow and a 37-mm. gun and machine guns in the turret. This tank was known as the General Lee. When it was fitted with a more squat British turret, it was called the General Grant. It was produced with riveted, cast and welded armour and with different types of engines because of production limitations. Many of its limitations were overcome in a design which followed.

The M-4 medium tank, known as the General Sherman, with added armour and the 75-mm. gun in the turret, was in production by April 1942, and it reached Africa in time for the battle of El Alamein. Undergoing continual development during the war with 76-mm. guns or a 105-mm. howitzer on some models, the M-4 became by far the most widely used Allied tank in the war. A total of 49,234 was produced. Its components featured simplicity and ruggedness. Of particular interest were the volute spring bogie-type suspension, the highly developed V-8 engine and the rubber-block, rubber-jointed tracks. A life of 3,000 mi. was not unusual for these tracks, compared to about 600 mi. for the metal-jointed German tracks. Aside from the fact that the numbers of the Sherman tank supplied to Allied armies made possible the massing of superior tank forces in critical areas, its speed, maneuverability and capacity for sustained operation under severe conditions made the Sherman tank a vital factor in Allied victory.

Late in the war a compromise between the medium Sherman and the heavy M-6 was made in the 45-ton General Pershing. It mounted a 90-mm. gun, used torsion bar suspension and a torque-matic stepless transmission. A few reached Europe before the war ended and some later also were landed on Okinawa. Light tanks went through a similar process of gun-calibre increase and the application of automatic transmissions adapted from motorcar design. The culmination of these was the M-24 or Chaffee 23-ton light tank, named after Maj. Gen. A. R. Chaffee.

The navy and marine corps had tested Christie amphibious tanks a few years after World War I. This led to a new concept in amphibious landings which received another impetus when the

Roebing rescue machine came to their attention in 1939. As the war went on, those vehicles were refined. Beginning with the marine corps landing on Betio (Tarawa), they were used more and more by the marine corps and eventually by the army. They were propelled in water by the motion of their tracks. Finally they were armoured and later turreted. Some were used as personnel carriers and some as accompanying artillery in landing operations. About 18,620 were built during the war.

**Great Britain.**—Immediately following the German invasion of Poland some members of the original World War I tank committee received permission to form a new committee at the ministry of supply. They produced a heavy gas-electric TOG tank, its initials representing "The Old Gang." The ministry meanwhile released for production a heavy Vauxhall tank. Disputes followed between Winston Churchill, then prime minister, and the committee with the result that the committee was dissolved and the Vauxhall tank became the 40-ton Churchill heavy tank.

Almost all existing tanks were lost at Dunkerque (Dunkirk). To catch up, vehicles were released for production with little testing. By the time the "bugs" were worked out, the tanks were obsolete. British tanks had a poor reputation because of this and because of lack of production inspection and control. Parliament investigated but was unable to fix responsibility. Meanwhile, production continued. Near the end of the war, British tank quality had improved and weapon calibres were more nearly the equal of the Germans.

Final models of the Churchill and Cromwell mounted 75-mm. guns. The faster and lighter Comets mounted 77-mm. guns. The Cromwell and Comet were in the cruiser class. In addition to combat tanks, the British devised several self-propelled guns and many special tanks such as the A.V.R.E. for throwing high explosive petards, "flails" for detonating land mines, carpet-laying tanks or "bobbins," flame throwers and others. About 24,000 tanks were produced, 3,600 were received from Canada and the United States furnished 25,600.

**U.S.S.R.**—The models laid down in 1938-39 and produced by 1940 revolutionized Soviet armour. The 26-ton T-34 medium was one of these. It was of the Christie type with wide (24 in.) tracks, had a low silhouette and a 30 m.p.h. speed provided by a good 500 h.p. liquid-cooled diesel V-12 engine. It was armed with a 76-mm. gun and later with an 85-mm. gun.

Another 1940 model was the KV heavy (named for Klementi Voroshilov, Soviet minister of defense), which weighed 52 tons and mounted a 76-mm. gun. The KV was much more heavily armoured than the T-34, which accounted for its greater weight, since in other respects it was much like the T-34. With these early wartime models the Soviets came into their own as designers, producers and users of fighting tanks. Before the war's end an-

other heavy tank, the Joseph Stalin, was to appear. It was a logical step from the T-34 and the KV, in the progression toward thicker armour and more fire power, with the 51-ton JS-2 model mounting a 122-mm. gun.

In addition to Russian production of about 100,000 vehicles, the United States furnished Russia 13,303 combat vehicles (tanks, self-propelled weapons and scout cars) under lend-lease. The British furnished 4,260 and Canada 1,220 tanks in addition to huge numbers of Bren carriers from both. Figures for Russian tank losses in the war have never been released but are believed to have been in the neighbourhood of 100,000. Russian equipment was designed to do the job with the least possible expenditure of man-hours to produce, with simplicity and with absolutely no emphasis on finish or crew comfort.

**Other Countries.**—Czechoslovakia, Italy, Japan, Poland and Sweden produced some excellent light and medium tanks before and during World War II, and Argentina produced a few medium tanks resembling the U.S. Sherman. In the main these vehicles were lightly armed and armoured. The Japanese vehicles were distinguished by their use of common components as well as by their use of diesel engines that reduced the possibility of fire, an ever-present hazard in a tank. Czech and Swedish vehicles, and

some Italian, were sold commercially to many smaller nations in the world.

### TANKS IN THE NUCLEAR ERA

During the postwar years the U.S.S.R. continued to emphasize tanks and increased the proportion of armoured units in the Red army. The Joseph Stalin (JS-3) tank, with sloping armour and dome-shaped turret, mounted a 122-mm. gun; the T-34 mounted an 85-mm. gun and weighed about 35 tons.

Both of these tanks were replaced by the T-10, which mounted a 122-mm. gun, and the T-54, which had a 100-mm. gun. The PT-76 amphibious tank of 1956 was followed by airborne, bridging and rocket projector tanks the next year.

Great Britain abandoned the basic distinction between cruiser and infantry tanks and instead adopted a single-purpose medium tank, the Centurion, later succeeded by the Chieftain. The latter had a multi-fuel engine and a remarkably low silhouette. The United States lacked a clear tank policy for a time after 1945 because of the overemphasis on nuclear weapons. Following the Korean War, during which tanks were used as artillery pieces, development of the hydrogen bomb and of tactical nuclear weapons led to a reappraisal and new designs. The M-60, with rounded cast armour, was adopted as the main battle tank of the U.S. army and went into quantity production in 1960. It mounted a British 105-mm. gun that became standard for all NATO tanks, was powered by a 750 hp. diesel engine, weighed 46 tons and carried a crew of four men.

France produced the light AMX13 and some excellent heavier vehicles. Sweden continued to manufacture and export tanks and in 1963 created the novel Bofors turretless tank. Japan resumed production of tanks for use by the Japan defense force. These tanks resembled U.S. medium tanks but had diesel engines and were scaled down somewhat to suit the Japanese soldiers.

Because tank v. tank warfare had not been visualized before World War II, armament had not been greatly emphasized, but the tank battles of World War II made guns the controlling factor in tank design. Postwar tanks, in fact, were identified in terms of their weapons rather than their weight. It was no longer customary to describe tanks as light, medium, or heavy but as light-gun, medium-gun, or heavy-gun tanks. The range of tank guns also increased. Most World War II tank fighting took place at distances of less than 1,000 yd. but after the war engagement at a range of 2,000 yd. or more was considered normal. In the 1960s the 120-mm. gun was considered the largest weapon that could be mounted on a tank with good effect. Such weapons required automatic loading devices, bore evacuators, electric primers, gyro-stabilizers, and highly developed range finders. For tank armour, light metals such as aluminum and magnesium were utilized, together with nylon and fibreglass components, so that armour protection could be provided with minimum weight. The fact that armour represented about one-third of the total weight of a tank indicated the importance of the use of lightweight materials.

With the advent of atomic missiles the concept of war underwent a complete change. Following a period of confused thinking, military concepts began to crystallize after 1950. Land warfare in the atomic age was believed most likely to take the form of thin screens of guerrillas or skirmishers capable of making sudden concentrations and attacks and equally quick dispersions.

Quick exploitation before an enemy recovers his balance after an atomic blast was considered to be of great importance. Tanks were thought to be well suited for use in atomic warfare because of the protection offered their crews from heat and flash. Their mobility would enable them to disperse and to reconcentrate rapidly as changes took place in a tactical situation either by the threat of or the use of nuclear missiles. Infantry on foot might be too slow and too vulnerable for such activity, and probably would be carried in armoured personnel carriers accompanying tank formations.

**TANKER**, a ship designed to carry liquid cargo in bulk. Its cargo is usually a petroleum product, either crude oil being carried from oil fields to refineries or gasoline being carried from refineries to distribution centres. The liquid is piped into the cargo space of the ship and is transported without use of barrels or other containers. Special tankers carry other liquids such as molasses, asphalt, wine, or liquefied petroleum gases, but the references in this article are all to oil tankers. Tankers differ from general-cargo ships in that they normally carry a full load of cargo in one direction and return without cargo.

Tankers vary in size from small coastwise vessels about 200 ft. long, carrying from 1,500 to 2,000 tons deadweight, up to huge vessels which are the largest ships afloat, approaching 1,000 ft. in length and carrying more than 150,000 tons deadweight. ("Deadweight" is the total weight that a ship can carry, consisting primarily of cargo but including fuel, water, crew, stores, etc.). Up to 1940 the upper limit in size was about 15,000 tons deadweight and about 500 ft. in length. In 1948, 28,000-ton "super-tankers" appeared, following in quick succession by tankers of 32,000, 45,000, and 65,000 tons. In the early 1960s the first tankers of more than 100,000 tons deadweight appeared, and vessels of more than 150,000 tons were laid down. By the mid-1960s the world tanker fleet amounted to more than 50,000,000 tons gross, accounting for one-third of world merchant shipping tonnage. The leading flags were Liberia and the United Kingdom (each with more than 8,000,000 tons gross), Norway (7,660,000 tons), and the United States (4,500,000 tons).

Experience with supertankers has shown that the direct cost of transporting oil goes down as the size of the tanker increases, apparently without limit; the limit on building larger tankers is the lack of suitable shore facilities for them. As more deepwater loading and unloading facilities are created, larger and larger tankers become economically feasible.

The speed of tankers has increased along with their size. In

1940 most tankers were powered with not more than 5,000 brake horsepower and made from 12 to 14 knots. In the 1960s most large tankers were given from 15,000 to 25,000 brake horsepower and made from 15 to 18 knots.

**Arrangement.**—Tankers almost invariably have their propelling machinery located in the stern. The cargo-oil space occupies about 60% of the ship's length; usually there is a general-cargo hold in the bow, along with ballast or fuel tanks. The cargo space is isolated from the forward and after portions by cofferdams, watertight compartments which are kept empty. A pump room is located just forward of the machinery space, with sometimes an additional pump room forward or amidships. There is a "forecastle" (additional topside deck at the bow) and a house amidships, containing the pilothouse, other navigational spaces, and usually quarters for a few of the crew. A "poop" (additional topside deck at the stern) extends over the machinery space and, together with higher levels of deckhouses, quarters the rest of the crew. In the 1960s the practice began of building "all-aft" tankers, in which there are no amidships structures, the navigating bridge and all accommodations being incorporated in the poop, above the main machinery spaces.

The cargo space is usually divided into two, three, or four rows of cargo tanks by longitudinal bulkheads; these are further divided into individual tanks (from 35 to 40 ft. long in large vessels) by transverse bulkheads. Access to the tanks is through oiltight hatches on the deck, cargo being loaded or discharged by means of the ship's own pumps, which may have a capacity in excess of 4,000 tons per hour.

Tanker crew accommodations are more livable than those of most vessels, because of the limited leave-time, which is often only about one day per passage. Single-person rooms, recreation lounges, and even swimming pools are fitted on the long-voyage tankers to enhance crew morale.

The density of the cargo carried by tankers varies from about 40 to more than 50 lb. per cu.ft. A tanker with enough capacity for a full deadweight cargo of light gasoline will have some empty tanks when carrying a full cargo of heavy crude oil.

Tankers are permitted by law to load more deeply, in proportion to their depth, than ordinary cargo ships. To be permitted this greater draft, they must provide special arrangements for fore-

BY COURTESY OF NEWPORT NEWS SHIPBUILDING AND DRY DOCK CO.

MEDIUM-SIZED OCEAN-GOING TANKER (27,000-TON DEADWEIGHT) OPERATING BETWEEN VENEZUELA AND NEW YORK

and-aft access for the crew in heavy weather, and for the quick freeing of the deck of seas which wash over it. The draft of tankers plying between the Arabian oil fields and Europe or the Atlantic coast of North America is limited by the Suez Canal to about 37 ft., although this depth is continually being extended by dredging. The extremely large tankers may be designed for drafts of 40 to 50 ft. but cannot use canals if fully loaded. A relatively high block coefficient is used to obtain maximum deadweight. The block coefficient is the ratio of submerged volume to the product of length, beam, and draft. The coefficient is frequently as high as 0.80, compared with about 0.60 to 0.70 for many passenger vessels and about 0.70 to 0.75 for most general-cargo ships.

**Construction.**—The internal bulkheads, and the stiffening members, are usually entirely welded. The outside plating (shell and deck) is also welded but in large tankers a few fore-and-aft seams are riveted. It has been found that a riveted seam will usually stop a crack in the plating, thus preventing a minor crack from becoming a major fracture. Small tankers may be completely welded.

The upper deck and the bottom shell of tankers are invariably framed longitudinally; that is, the stiffening members that support the plating are run fore-and-aft instead of transversely as in other types of ships. In many tankers the side shell plating is also longitudinally framed. The thickness of the shell plating

A

B

DECK ARRANGEMENT OF A TANKER: (A) PROFILE; (B) PLAN VIEW SHOWING CARGO TANKS

will vary from about  $\frac{3}{4}$  in. for a small tanker to about  $1\frac{1}{2}$  in. for a very large tanker.

Tankers are shorter lived than most steel ships because of the corrosive nature of their cargo. Crude-oil cargoes deposit corrosive sludges on the bottom and gasoline cargoes have a corrosive effect on the steel of the tanks. As a result, a tanker may last only 12 years instead of the 20-year life of a cargo ship, although protective coatings have been developed that help to withstand the corrosive effects of petroleum products.

This deterioration takes place mainly in the cargo spaces, leaving the bow, the stern, and the machinery with years of useful life. It is, therefore, not unusual for an owner to scrap the cargo-tank portion of an old tanker and have a new one built and fitted into the old bow and stern. Since the new part is usually made larger than the discarded section, this procedure is sometimes called "jumboizing." Sometimes the vessel will be completely converted for the carriage of grain, iron ore, or other bulk cargoes.

**TANNER, HENRY OSSAWA** (1859–1937), U.S. Negro painter, whose style was naturalistic and whose subject matter was most often biblical, was born at Pittsburgh, Pa., on June 21, 1859. He was the son of BENJAMIN TUCKER TANNER (1835–1923), bishop of the African Methodist Episcopal Church from 1888 to 1908 (when he retired at his own request) and author of a number of books, including *An Apology for African Methodism* (1867) and *The Negro's Origin* (1869). Henry Tanner was a pupil of Thomas Eakins, in Philadelphia, and of J. P. Laurens and Benjamin Constant in Paris, where he lived thereafter. He first exhibited at the Salon in 1895. Examples of his work may be seen at the Philadelphia (Pa.) Museum of Art; Los Angeles (Calif.) county museums; Art Institute of Chicago (Ill.); Metropolitan Museum of Art, New York City; and other public collections. He was a knight of the Legion of Honour and a member of several painters' societies. Tanner died in Paris on May 25, 1937.

**TANNER, VÄINÖ ALFRED** (1881–1966), Finnish statesman, an outstanding exponent of patriotic and democratic policies for his country's working class. He was born in Helsinki on March 12, 1881. Early associated with the cooperative movement, he entered the Finnish Parliament as a Social Democrat in 1907. After the Civil War (1918), he worked successfully to revive his party, orientating it toward Western-type parliamentarism. From Dec. 11, 1926, to Dec. 9, 1927, he was prime minister.

Tanner became foreign minister when the U.S.S.R. was attacking Finland (see WORLD WAR II). Under his leadership, working-class solidarity made possible Finland's heroic resistance in the "Winter War." After the peace of March 12, 1940, he became minister of supply, but Soviet pressure enforced his resignation in August. When war had been resumed against the U.S.S.R., he became minister of commerce and industry (July 3, 1941) and then of finance (May 22, 1942–Aug. 4, 1944). Under the Soviet-Finnish armistice, the Communists accused him of being one of those "responsible for the war": arrested on Nov. 6, 1945, he was sentenced, on Feb. 21, 1946, to  $5\frac{1}{2}$  years' imprisonment. Released on Nov. 21, 1948, he returned to Parliament. On April 25, 1957, he was reelected chairman of the Social Democratic Party. He died in Helsinki on April 19, 1966. (E. K. I. J.; X.)

**TANNHÄUSER** (c. 1200–c. 1270), German lyric poet who became the hero of a popular legend. As a professional Minnesinger (*q.v.*) he served a number of noble patrons, and from his references to them it can be concluded that his career spanned the period c. 1230–c. 1270. Not much is known of his life, except that he traveled widely and almost certainly took part in the Crusade of 1228–29. There are six extant *Leiche* (lyric lays) by Tannhäuser, a few dance songs and love songs (the latter in a parodistic vein), and a group of *Sprüche* (gnomic poems).

The Tannhäuser legend is preserved in a popular ballad traceable to 1515; the origins of the legend itself probably lie in the 13th century. Enticed to the court of Venus, Tannhäuser lives a life of earthly pleasure, but soon, torn by remorse, he makes a pil-

grimage to Rome to seek remission of his sins. The pope tells him that, as his pilgrim's staff will never put on leaf again, so his sins can never be forgiven. In despair Tannhäuser returns to the court of Venus. Shortly afterward his discarded staff begins to put forth green leaves. The pope sends messengers to search for Tannhäuser, but he is never seen again.

The legend acquired great popularity among 19th-century Romantic writers. Its most famous presentation is in Wagner's "music drama" *Tannhäuser* (first produced in 1845).

Siebert, *Der Dichter Tannhäuser: Leben, Gedichte, Sage* (1934); M. Lang, *Tannhäuser* (1936). See also L. Wolff in W. Stammer, *Die deutsche Literatur des Mittelalters: Verfasserlexikon*, vol. iv (1953). (Rd. J. T.; X.)

**TANNIN** (TANNIC ACID), the generic name for a widely disseminated group of plant products, so named from their property of converting rawhide into leather (*q.v.*). They are soluble in water, and their solutions, which have an acid reaction and an astringent taste, are coloured dark blue or green by iron salts, a property utilized in the manufacture of ink (*q.v.*). Tannins occur normally in the roots, wood, bark, leaves, or fruit of many plants. They also occur to the extent of 45–65% in galls, pathological growths on species of oak and sumac resulting from the attack of an insect. (See also TEA; GALL, PLANT.)

Tannins may be classified into two main groups depending upon the products formed by boiling with mineral acids. Hydrolyzable tannins yield various water-soluble products, such as gallic acid ( $(HO)_3C_6H_2CO_2H$ ), protocatechuic acid ( $(HO)_2C_6H_3CO_2H$ ), and sugars. Under similar treatment, condensed tannins, by far the larger group, form insoluble precipitates called tanners reds or phlobaphenes.

Gallotannin or common tannic acid is the best known of the hydrolyzable tannins. It is obtained from Chinese or Aleppo galls by extraction with water or organic solvents. When pure, it is a slightly yellow or tan amorphous powder or mass. It is very soluble in water, less so in alcohol, and practically insoluble in ether. Hydrolysis produces gallic acid and glucose. Aleppo galls yield, in addition to gallic acid, some ellagic acid, a constituent also of myrobalan, divi-divi, algarobilla, and valonia tannins. Tara, the pods from *Caesalpinia tinctoria*, a plant indigenous to Peru, contains 40–55% of a gallotannin similar to that from galls and has become an important source for refined tannin and gallic acid. The chestnut oak (*Quercus prinus*) yields a hydrolyzable tannin important in leather manufacture.

Among the important condensed tannins are the extracts from the wood or bark of quebracho, mangrove, and wattle. The structures of these tannins are uncertain but many workers believe them to be related to the flavan catechin found in gambier. Refined analytical methods have shown that many natural tannins are mixtures of several closely related substances.

**Uses.**—Besides their principal application in the manufacture of leather, tannins find use as a constituent to reduce the viscosity of drilling mud for oil wells, in boiler water to prevent scale formation, and in the clarification of wine and beer. Tannic acid is employed as a mordant in the dyeing of cotton with basic dyes. Because of its styptic and astringent properties, it has been used in the treatment of tonsillitis, pharyngitis, hemorrhoids, and various skin eruptions. The use of tannic acid in the treatment of burns, formerly widely accepted, has become less popular. Tannic acid has been administered internally to check diarrhea and intestinal bleeding, and also as an antidote for metallic, alkaloidal, and glycosidic poisons with which it forms insoluble precipitates.

**TANNING:** see LEATHER; TANNIN.

**TANTALUM**, a metallic element closely associated with niobium in ores and in properties, was discovered in 1802 by the Swedish chemist A. G. Ekeberg when examining minerals from Finland and Sweden. He named it tantalum after the mythological character Tantalus because of the tantalizing problem of

dissolving the oxide of the new metal in acids. The previous year, 1801, C. Hatchett, an English chemist, also had discovered a new element that he named columbium. Because of the similarity of compounds of the two elements, they were regarded as being the same until in 1844 H. Rose, a German chemist, discovered both tantalum and a new element that he named niobium (for Niobe, daughter of Tantalus) in the mineral columbite. Later, however, Rose realized that niobium and columbium were the same element (*see* NIOBIUM).

In 1866 niobium and tantalum compounds were actually separated by Swiss chemist J. C. G. de Marignac, thus permitting studies of the compounds of each element. Although some impure tantalum was produced by several early investigators, it was not until 1903 that the first ductile tantalum was produced by W. von Bolton in Germany. This ductile tantalum was used for incandescent lamp filaments until tungsten began to replace it in 1909. The first production of tantalum in the United States started in 1922. About this time C. W. Balke discovered that intentionally oxidized tantalum made an excellent rectifier of alternating current and its use in radio receiving sets and capacitors was established. Since then the use of tantalum in the electronics and chemical industries has grown steadily.

**Occurrence.**—Tantalum is a relatively rare metal. It ranks 54th in order of concentration of elements in the earth's crust and is found only in minerals which also contain niobium. The principal mineral is a ferrous manganese tantalate-niobate,  $(\text{Fe, Mn})(\text{Ta, Nb})_2\text{O}_6$ . If the tantalum oxide content exceeds the niobium oxide content, the mineral is called tantalite. If the niobium oxide content is greater, it is called columbite (*see* COLUMBITE [TANTALITE]). Tantalum also is found in other minerals, including pyrochlore, fergusonite, samarskite, euxenite, polycrase, and microlite, in each of which the niobium content generally exceeds the tantalum by a significant amount.

Tantalite and columbite usually are found in pegmatite dikes in quantities that rarely exceed a few pounds per ton. The chief sources are in Africa (Nigeria and Democratic Republic of the Congo), in eastern Brazil, and in Australia, generally as by-products of tin-mining operations. Tantalite minerals have been found in South Dakota and microlite in New Mexico.

**Production.**—Tantalum metal may be separated from the ore by several methods, each involving a series of chemical steps. In each process emphasis is placed on the separation of tantalum from niobium, since this is the most difficult step in the recovery process. In the classical method developed by Marignac in 1866, pulverized ore concentrates are fused with sodium hydroxide to form tantalates and niobates, which are leached with water and hydrochloric acid to remove most of the other metallic impurities and form insoluble tantalum and niobic acids. The mixed acids are dissolved in warm hydrofluoric acid to which is added a potassium compound so that a solution containing potassium fluotantalate,  $\text{K}_2\text{TaF}_7$ , and potassium niobium oxyfluoride,  $\text{K}_2\text{NbOF}_6$ , is formed. As this solution cools, the  $\text{K}_2\text{TaF}_7$  precipitates, leaving the  $\text{K}_2\text{NbOF}_6$  in solution. The  $\text{K}_2\text{TaF}_7$  crystals are separated from the slurry by filtration and dried. They may then be reduced to obtain tantalum powder by electrolysis or sodium reduction.

A newer process based on work conducted at the U.S. Bureau of Mines in the early 1950s is now being widely used. Acid aqueous solutions of tantalum and niobium fluorides are placed in contact with methyl isobutyl ketone. At low acidity tantalum fluoride is extracted by the organic phase, and at high acidity the niobium fluoride is extracted. Once separated, the tantalum fluoride can be converted to  $\text{K}_2\text{TaF}_7$  and reduced to tantalum metal.

Other methods of separating tantalum and niobium have been developed but are not used to any great extent. Tantalum metal is produced by powder metallurgy techniques (*see* POWDER METALLURGY: Processes and Products: Refractory Metals).

**Properties and Applications.**—Tantalum occupies the position in Group VA in the 6th period of the periodic table just below that of niobium. Its normal valence is 5, but in some compounds it can have the valence of 2, 3, or 4. A ductile metal having a silvery-gray colour, it is characterized by its high density, high melting point, and excellent resistance to attack by all acids ex-

Some Physical Properties of Tantalum

Symbol	Ta
Atomic number	73
Atomic weight	180.948
Isotopes	176, 177, 178, 179, 180, 181 182, 183, 184, 185, 186 body-centered-cubic
Crystal system	2096
Melting point (°C)	5425±100
Boiling point (°C)	12.45
Electrical resistivity at 25°C, microhm-cm	0.130
Thermal conductivity at 20°C, cal	0.827×10 <sup>-6</sup>
Magnetic susceptibility, 25°C, cgs units	50,000
Tensile strength (approx.) psi	27×10 <sup>6</sup>
Modulus of elasticity (approx.) psi	0.034
Specific heat, 25°C, cal/g	34.6 to 41.5
Latent heat of fusion, cal/g	995 to 1021
Latent heat of vaporization, cal/g	4.38
Superconducting transition temperature (°K)	16.6
Density (g/cc) at 20°C	7.8×10 <sup>-6</sup>
Coefficient of linear expansion 27–2,900°C, per degree	

cept hydrofluoric and fuming sulfuric at ordinary temperature. The resistance to acids is related to the formation of a natural, thin, passive-oxide surface layer similar to that formed on stainless steel, titanium, and aluminum.

The applications for tantalum are based on its properties (high melting point, chemical inertness, and strength and ductility) and the dielectric properties of its oxide surface film. The most important uses for tantalum are in electrolytic capacitors and corrosion-resistant chemical equipment. Tantalum capacitors take advantage of the dielectric surface oxide film that can be formed on tantalum by anodizing. Tantalum capacitors have the highest capacitance per unit volume of any capacitors and are used extensively in miniaturized electrical circuitry. Chemical process equipment manufactured from tantalum is used for sulfuric acid concentrators, hydrochloric acid production, plating solutions, and a wide variety of processes requiring chemical inertness. Other uses include getters and components in electron tubes, rectifiers, and prosthetic devices.

Although tantalum has a very high melting point, it is not used as a high-temperature structural material to any great extent because of its rapid reaction with oxidizing environments. This high-temperature reactivity is in contrast to its chemical inertness at ambient temperatures and is related to the kinetics of oxidation at the different temperatures. At low temperatures a thin, tightly adherent uniform oxide film is formed, which resists chemical attack. At high temperatures the oxidation reaction proceeds very rapidly, forming a porous, nonadherent oxide scale which is easily penetrated by additional oxygen from the environment, causing the reaction to proceed very rapidly. At temperatures above about 1,400° C (about 2,550° F) the tantalum-oxygen reaction is so rapid that tantalum actually burns.

Several tantalum alloys have been developed that have useful structural properties at temperatures above about 1,090° C (2,000° F). Because of the high oxidation rate of tantalum and its alloys at these high temperatures, it is necessary to use protective coatings for use in air or other oxidizing environments. Typical protective coatings are silicides and aluminides formed by reacting the tantalum metal with an appropriate silicon or aluminum compound; these coatings are generally brittle and must be handled with care. In the absence of oxidizing environments, tantalum alloys may be used without protective coatings. An alloy containing 7.5% tungsten is used in some vacuum tubes for filament springs where retention of elasticity at high temperature is required. Tantalum is also used for high-temperature furnace components operating in vacuum or inert atmospheres.

**Tantalum Compounds.**—The most important tantalum compound is the carbide, TaC, which is used in the manufacture of some hard carbide tools for machining steels and other metals. Tantalum carbide may be made by the direct reaction of tantalum with carbon or the reaction of carbon with tantalum oxide. Tantalum oxide is used as an ingredient in some types of high refractive index optical glass. Many compounds of tantalum are known, but their uses are limited.

**TANTIA TOPI** (TATYA TOPE) (c. 1819–1859), a leader during the Indian Mutiny (q.v.; 1857–58). His real name was Ramchandra Panduranga. He was a Maratha Brahman in the service of the former peshwa Baji Rao and of his adopted son Nana Sahib. Though without formal military training, he proved to be the rebels' most effective general. He was present at the Cawnpore (Kanpur) massacre: in early November 1857 he took command of the revolted Gwalior contingent and drove Gen. C. A. Windham into his entrenchments at Cawnpore on Nov. 27–28. He was defeated by Sir C. Campbell on Dec. 6 but remained at Kalpi, the scene of his defeat. In March 1858 he moved to the relief of Jhansi, where the rani was besieged by Sir H. Rose. Defeated here, he welcomed the escaping rani at Kalpi and then made a successful dash to Gwalior on June 1. He was defeated and his army broken up on June 19. For some time he carried on guerrilla warfare and finally took to the jungle, where he was betrayed and executed on April 18, 1859.

See S. N. Sen, *Eighteen Fifty-Seven* (1957). (T. G. P. S.)

**TANTRISM**, a system of esoteric practices used in Hinduism, Jainism, and Tibetan Buddhism for both the attainment of spiritual experience and the fulfillment of worldly desires. *Tantra* designates a particular group of post-Vedic Sanskrit treatises (see SANSKRIT LITERATURE: *Puranas and Tantras*), heterogeneous in content, that deal with secret practices aiming at the purification of the body and the control of physiological and psychological processes. By such purification and control, it is believed, the body and the mind may be made perfect media for the realization of the highest truth, as also of all that concerns the worship of gods and goddesses, rites and rituals, and black magic. Tantrism is practised in India, Nepal, Bhutan, and especially Tibet, the great seat of tantric Buddhism (see TIBETAN BUDDHISM).

Tantrism is mostly concerned with practical methods and lays little stress on religious theories, which it accepts from the main philosophical schools of Hinduism. Theologically it holds that the nondual Supreme Reality has two aspects, Shiva (male) and Shakti (female), the one representing pure consciousness and transcendent passivity, the other representing mental activity (see SHIVAISM; SHAKTISM). This truth regarding Shiva-Shakti as well as the nonduality of the Absolute is to be realized within the human body, which is believed to be a "microcosm" or epitome of the universe. The spinal cord represents the fabulous Mt. Meru, while the three main nerve connections (*ida*, *pingala*, and *sushumna*) running along the left, the right, and the middle of the spine represent the three sacred rivers Ganges, Jumna, and Sarasvati; the breathing process represents the course of time. Shakti, serpentwise coiled and dormant in the lowest plexus of the body, has to be awakened and made to move upward through the five higher plexuses along the spinal cord, so as to be united with Shiva, residing in the sixth plexus between the eyebrows. This union brings about the transcendently blissful realization of supreme nonduality in a thousand-petaled lotus in the cerebrum.

Tantrism is associated with some unconventional practices. The *Panca-ma-kara*, the five things whose names begin with the letter *m* (*madya*, *mansa*, *matsya*, *mudra*, and *maithuna*, respectively wine, meat, fish, parched grain, and sexual union), have been interpreted literally or as representing five elements of the psycho-physical Hatha Yoga (see YOGA). Tantrism, in an attempt to reach a supramental and depersonalized ecstasy, advocates the methodical use of sexual union as a Yogic process, without the pleasurable completion of the sex act; this, it is believed, creates a state of heightened suspense leading to the complete arrest of all mental processes, in a "mystic" sense of oneness with the basic reality of the universe. In Tantrism caste restrictions are reduced to a minimum; women are often revered as manifestations of Shakti, men being manifestations of Shiva. Tantrism also upholds the efficacy of *yantras* (mystic diagrams) and of *mantras* (mystic syllables or formulas; see MANTRA). See further BUDDHISM: *Regional Variations in Buddhism: Tantric Buddhism*.

See Sir John Woodroffe, *Principles of Tantra*, 2nd ed. (1952).

**TANUCCI, BERNARDO, MARCHESE** (1698–1783), the foremost statesman of the Kingdom of Naples-Sicily in the first decades of Bourbon rule. He was born at Stia, in the Casentino (eastern Tuscany), on Feb. 20, 1698. He was teaching civil law at Padua when two opportune memoranda of his attracted the notice of the Bourbon infante Don Carlos—the future Charles III of Spain. Don Carlos took him into his service (1732) and, on conquering Naples, appointed him secretary of state for justice (1734). As minister of foreign affairs and of the royal household (from June 10, 1755), Tanucci intelligently carried out the king's policy of making Naples-Sicily a genuinely Italian state, free from subjection to Spanish interests. When his patron became king of Spain and resigned Naples (1759), Tanucci, as a member of the council of state, was one of the regents for the young king Ferdinand (see FERDINAND I of the Two Sicilies).

At the end of the regency, Ferdinand appointed Tanucci premier secretary of state (Jan. 1, 1768) and keeper of the royal seal. Tanucci antagonized the queen Maria Carolina. Hearing that she had joined a masonic lodge, Tanucci produced a decree against the Freemasons; but the victims of his severity (all of them aristocrats) rallied so much support that his position became untenable. Dismissed by Ferdinand on Oct. 25, 1776, Tanucci retired to Santo Giorgio a Cremano, where he died on April 29, 1783.

(E. Po.; X.)

**TANZANIA, UNITED REPUBLIC OF.** An independent sovereign state of east central Africa, within the Commonwealth of Nations, consisting of the republics of Tanganyika and Zanzibar; the latter is composed of the two large islands Zanzibar and Pemba, with smaller islands. Pop. (1964 est.) 10,325,000 (Tanganyika 9,990,000; Zanzibar 335,000). Of the total area of 362,844 sq.mi. (939,767 sq.km.), Tanganyika comprises 361,800 sq.mi. and Zanzibar 1,044 sq.mi. Zanzibar Island lies about 20 mi. (32 km.) off the coast of Tanganyika, Pemba Island about 25 mi. (40.2 km.). The capital is Dar es Salaam (q.v.).

## I. PHYSICAL GEOGRAPHY

### A. TANGANYIKA

#### 1. Relief and Drainage.—

The greater part of Tanganyika consists of an immense plateau varying in altitude from 3,500 to 4,500 ft. (1,000 to 1,400 m.). To the west it is bounded by steep escarpments of the western arm of the Great Rift Valley, which contains Lakes Tanganyika and Rukwa. The valley forks north of Lake Nyasa, and the eastern arm, which passes through the centre of Tanganyika, is less distinct; only the western wall is seen, as a cliff of varying height, until the troughlike characteristics of the Gregory Rift become noticeable near Kenya.

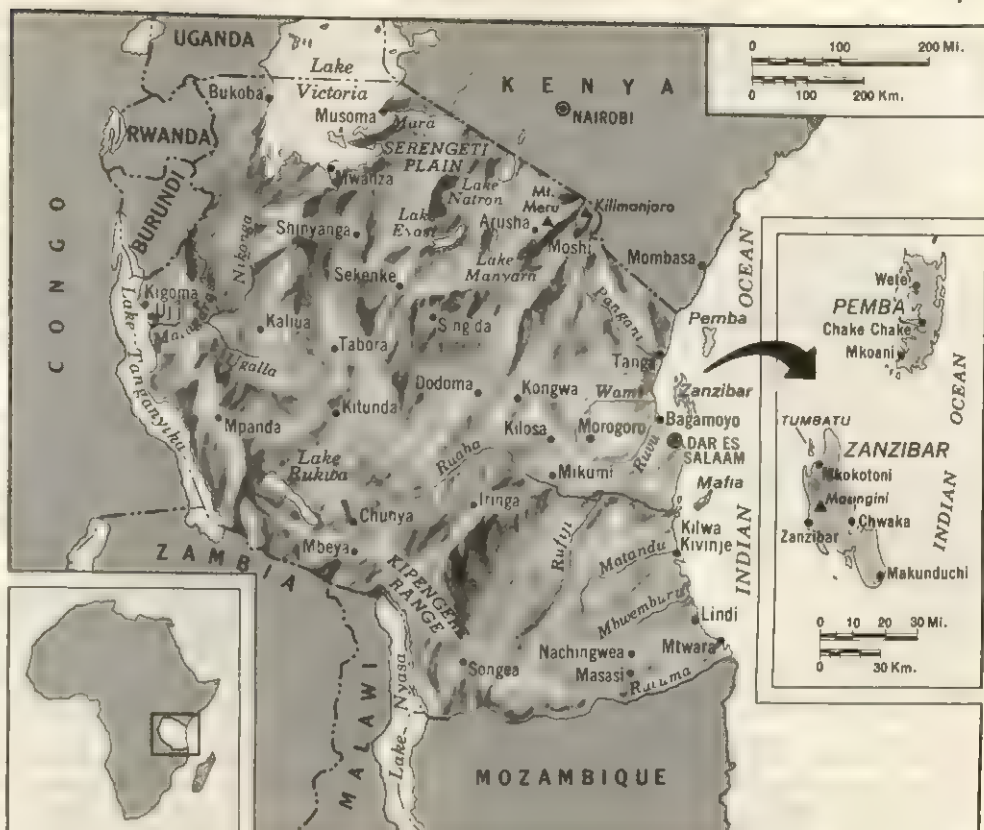

The mountain systems are grouped in the northeast and southwest, with a ridge of highland between the two forming the eastern margin of the plateau. In the north are the volcanic peaks of Kilimanjaro (19,340 ft. [5,895 m.]) and Meru (14,979 ft. [4,566 m.]), and the Crater Highlands, with the famous game-filled Ngorongoro Crater. Running south-east from Kilimanjaro to the coast are the Pare and Usambara ranges. The Nguru and Uluguru mountains rise behind the coastal plain farther south. At the northern end of Lake Nyasa are the Livingstone Mountains, the Kipengere Range, the Poroto Mountains, Mt. Rungwe, and, farther west, the Ufipa Plateau.

Tanganyika has few permanent rivers, and most of the Central Plateau is devoid of running water throughout the dry season; only half the country is supplied with natural water throughout the year. The main rivers flowing to the Indian Ocean are the Pangani (Ruvu), which rises on Kilimanjaro; the Wami, whose tributary the Kinyasungwe-Mukondokwa has cut back into the plateau edge to capture some of the drainage of the interior; the Ruvu (Kingoni); the Rufiji, whose many tributaries include the Ruaha, which has also cut back through the plateau edge, the Kilombero, the Luwigu, and the Mbarangandu; and, farther south, the Matandu, Mbweburru, Lukuledi, and the Ruvuma, which forms the southern boundary of the country.

The Mara, Kagera, and other rivers flow into Lake Victoria, the Malagarasi into Lake Tanganyika, and the Songwe and Ruhuhu into Lake Nyasa. Thus, Tanganyika forms the divide separating the headwaters of the three greatest rivers of Africa—the Nile, Congo, and Zambezi. About half of the great lakes Tanganyika and Victoria lie within the Tanganyikan borders. Lake Nyasa is wholly outside the country, though it forms part of the south-western border (with Malawi).

**2. Climate.**—The climate is characterized by alternating wet and dry seasons. The small seasonal variation in temperature is much exceeded by the diurnal range, which is greatest over the Central Plateau, where it may be as much as 36° F (20° C), and least in coastal and lake regions, where it is about 14° F (8° C). Afternoon temperatures above 90° F (32° C) may prevail during the hottest months, from October to May. The equatorial climate is modified by lower temperatures on the high plateaus and mountains, giving a range of climates from the hot, humid coastal belt to regions of snow and ice on Kilimanjaro.

The rainy season is from November or December to April or

TANZANIA: MAJOR CITIES AND SURFACE FEATURES

May, when humidities may be uncomfortably high near the coast, with drought for the rest of the year. But the Kenya pattern of long and short rains prevails in northeastern Tanganyika, where the main rains are during March–May and the short rains in November–December. Much of the territory is semiarid, but very heavy rain falls at the northern end of Lake Nyasa (more than 100 in. [2,500 mm.]) and on the western shore of Lake Victoria (more than 80 in. [2,000 mm.]), where storms off the lake are concentrated by the prevailing winds. Annual variations are considerable, and because of unreliable rainfall extensive areas are suited only to pastoral development.

**3. Soils and Vegetation.**—Soil types include those of the plateaus, with a horizon of concretionary ironstone (murrum), deep red earths, volcanic soils, calcareous black soils, sandy soils, and alluvial soils. With some exceptions, soils are poor, deficient in plant nutrients, and easily leached. Accelerated soil erosion is a serious problem. Miombo woodland (*Isroberlinia-Brachystegia*) occupies extensive areas in the west and south, and on open steppes grow scattered *Acacia* and myrrh trees (*Commiphora*). The baobab and *Euphorbia candelabra* are also characteristic. Evergreen forest, in which *Podocarpus* (yellowwood), *Chlorophora excelsa* (muvule, muule, or iroko), and various cedars are of economic value, occurs on mountain slopes. Above the forest may be found bamboo and open woodland with giant heathers. Higher still, Afro-alpine tree communities include giant species of *Senecio* (groundsel) and *Lobelia*. Coconut palms and casuarinas abound near the coast, as well as extensive mangrove swamps south from the Rufiji Delta.

**4. Animal Life.**—The country is unsurpassed in the number and variety of its wildlife: elephant, giraffe, zebra, rhinoceros, buffalo, together with lion, leopard, cheetah, hyena, and other carnivores; numerous varieties of antelope, including impala, gazelle, and wildebeest; snakes, lizards, chameleons, crocodiles, and other reptiles; and more than 1,000 varieties of birds, including game birds. Chimpanzees are found in the mountains east of Lake Tanganyika. The sitatunga is found in certain swamps, and the gerenuk (another rare antelope) in the Arusha, Kilimanjaro, and Tanga regions.

The Serengeti National Park is the most important reservation for plains game in Africa; it no longer includes the Ngorongoro Crater, which has become a separate conservation unit. Other smaller national parks include those of Ngurdoto Crater, near Arusha, and Lake Manyara. Of the game reservations the largest are the Selous and Rungwa River; smaller ones include the whole areas of Mt. Kilimanjaro and Mt. Meru and others at Lake Natron and Katavi Plain. (See further NATIONAL PARKS AND NATURE RESERVES.) The Rukwa Valley is one of the swarming areas of the locust, and game conservation there is administered by the Red Locust Research Association. Some of the game reservations have suffered from poaching and insufficient supervision, but at a conference on wildlife conservation held at Arusha in 1961 the Tanganyikan government announced a conservation policy more advanced than that adopted by any other African state. The tsetse fly (chiefly *Glossina morsitans*) infests wide areas, spreading sleeping sickness, but is being steadily eradicated by tree clearance and the establishment of permanent farms. Rainbow and brown trout were introduced into rivers of the northern and southern highlands, and Nile perch and tiger fish are caught in Lake Tanganyika. From November to March coastal big-game fishing is popular off Tanga and Mafia. (J. M. KE.)

## B. ZANZIBAR

**1. Geology, Relief, and Soils.**—Both Zanzibar and Pemba are believed to have once formed part of the continent, the separation of Pemba having occurred during the Miocene Age, while Zanzibar dates from the Pliocene and Pleistocene ages. A deep channel, the result of rift faulting in the late Miocene, separates Pemba from the mainland and Zanzibar. Various types of limestone form the base of both islands. Raised sands and sandstones also occur together with varied residual deposits similar to alluvial strata on the adjacent mainland. Extensive weathering of the limestones combined with erosion and earth movements have resulted in a variety of soils, including red earths, loams, clays, and sands. Flat areas of coral limestone occur to the east, south, and north of Zanzibar and on the small islands to the west. Similar formations occur on the eastern seaboard of Pemba and on most of the islands. In places the coral is overlain by shallow red earth or alluvium.

The general impression of Zanzibar when approached from the mainland is of a long, low island with small ridges along its central north-south axis. Coconut palms and other vegetation cover the land surface. It is 52 mi. (84 km.) at its greatest length and 27 mi. (43 km.) wide. The highest point of the central ridge system is Masingini, 390 ft. (119 m.) above sea level. Higher ground is gently undulating and gives rise to a few small rivers, which flow west to the sea or disappear in the coral country. Two springs north of Zanzibar City provide an excellent water supply. Much of Pemba consists of small but steep undulating hills, and the western and southern coastline is deeply indented with creeks and bays.

**2. Climate.**—The climate is typically insular, tropical and humid. Rainfall is good, reliable, and well distributed. Northeast trade winds blow from December to March and southeast trade winds from May to October. Mean annual rainfall at Kizimbani (central Zanzibar Island) is 71 in. (1,800 mm.) and at Makunduchi (in the southeast) 63 in. (1,600 mm.). The "long rains" occur between March and May and the "short rains" during October-December. The two annual clove harvest periods are related to the seasonal rainfall pattern. From June to October is regarded as the "cool" season and November to March the "hot" season. Mean maximum temperature in Zanzibar City is 84° F (29° C) and mean minimum 77° F (24.8° C). The rainfall of Pemba is greater than that of Zanzibar, but the climate is otherwise similar. Figures for Wete, the capital, are: mean annual rainfall 77 in. (2,000 mm.), mean maximum temperature 86° F (30° C), mean minimum temperature 73° F (23° C).

**3. Vegetation.**—Small patches of indigenous forest and isolated large trees support the view that much of Zanzibar Island was originally covered by dense evergreen forest. The open coral outcrop country supports a dense thicket vegetation. The flat clay

plains are grass covered. A noteworthy feature of the Chaam Plain in the north is the large number of palmyra palms. In damp valleys, papyrus, sedges, and tall grasses occur. In the few small streams and shallow swamps the giant aroid and, occasionally raffia palms are found. Near the seashore the baobab, casuarina and screw pine are characteristic trees, though many coconuts also occur on cultivated land above high-tide level. There have been many plant importations to Zanzibar over a long period of time. A feature of sheltered bays and creeks, especially in Pemba is the dense stands of mangrove, two species of which yield bark rich in tannin, while others provide valuable timber.

**4. Animal Life.**—The major wild animals include leopard (a race peculiar to Zanzibar), civet cat, mongoose, two species of monkeys, lemur, the African pig, forest duiker, pygmy antelope tree cony, squirrel, elephant shrew, and about 20 species of bats. Many of these animals are confined to the sparsely inhabited, bush-covered coral "Wanda" areas. Reptile life includes about 30 forms of snakes, five of which are poisonous, and the giant monitor. Frogs, toads, and tree frogs occur widely. Bird life is less varied and abundant than on the African mainland; excluding sea birds, 102 resident species have been recorded in Zanzibar and 73 in Pemba.

A great variety of fish is found both in the shallow coastal waters and in the deeper water of the Indian Ocean off the coral reef formations. Game fish include marlin, sailfish, tunny, and barracuda. Certain sea cucumbers found in shallow waters are collected, dried, and exported as bêche-de-mer (trepang). Shellfish of many species abound.

The insect fauna is not notably different from that of the nearby mainland. Mosquitoes breed freely during the rainy seasons. Insect pests such as the coreid bug (*Pseudotheraptus wayi*), which attacks coconuts, and animal pests and parasites, such as the tsetse fly and ticks (which transmit East Coast fever to cattle), have been the subject of research and control. Butterflies and moths though common, do not offer the same variety as that in parts of the East African mainland. The Zanzibar Museum in Zanzibar City contains a first-class natural history section. (F. B. WI.)

## II. THE PEOPLE

### A. TANGANYIKA

**1. Ethnography and Linguistics.**—Most of the peoples of Tanganyika are Bantu-speaking Negroes. They are among the northernmost Bantu peoples and were subjected to non-Bantu invasions from the north and to Arab contact from the coast. In the north and west are the southerly Interlacustrine Bantu kingdoms of Ha (numbering about 290,000), Haya (325,000), Fipa (80,000), and the smaller Kerewe, Zinza, Subi, and others. (See BANTU [INTERLACUSTRINE]; BANTU LANGUAGES.) There are about 120 different tribes, and several of the large ones have been affected by the Interlacustrine invasions, notably the Sukuma south of Lake Victoria (more than 1,000,000) and the Nyamwezi in west Tanganyika (363,000). In the south, tribes related to those of Zambia and Malawi include the Nyakyusa (q.v.; 220,000), Bena (196,000), and the Ngoni and Yao (qq.v.). In the centre and north, most Bantu tribes have been influenced culturally by the Masai (q.v.); they include the Gogo in the Dodoma region (299,000), Hehe (q.v.; 220,000), Arusha (68,000), Kuria (65,000) and Nyaturu (185,000). In the northeast dwell several tribes closely related to the Kikuyu and Kamba of Kenya, including the Chagga around Mt. Kilimanjaro (more than 300,000), Sumbaa (194,000), and Pare (126,000). In the east and southeast are tribes that, unlike the others, reckon descent matrilineally and have been affected by Arab influence; among these are the Makonde of the Mtwara region (334,000), Luguru (202,000), Zaramo (183,000), Mwera (138,000), Zigua (134,000), Makua (123,000), and Rufiji (75,000).

The Great Rift Valley area in the north seems to have been a refuge for some non-Bantu tribes that were left unaffected by the many migrations of Bantu Negroes. The Hadzapi or Kindiga hunters and gatherers reputedly akin to the Bushmen of southern Africa, live on the Lake Eyasi flats; the pastoral Sandawe are said to be related to the Hottentots. The Iraqw (134,000) and

some small outlying groups are linguistically unrelated to any other known peoples; their language may have Cushitic affinities. There are also in the north about 50,000 Masai and 30,000 Barabaig, Nilo-Hamitic speakers, who migrated from Kenya and who, as warrior tribes, greatly influenced their neighbours.

Apart from the Hadzapi, Sandawe, Masai, and Barabaig, all the tribes are agriculturalists, traditionally growing corn (maize) and millets. Save for the few kingdoms or chiefdoms (Ha, Fipa, Chagga), these peoples lack centralized political authority; their density of population and political cohesion are low. Except on the coast and in some older inland towns, where Islam predominates, the African population generally follows traditional religion, although Christianity has made some headway. The slave trade, based at first on the coast, later on Zanzibar, had devastating effects throughout central and southern Tanganyika, much of which remains thinly populated.

**2. Population Statistics.**—The population is unevenly distributed. One-quarter of the African peoples dwell around the shores of Lake Victoria; other large concentrations are in the highlands (especially Mt. Kilimanjaro) and the coastal towns. In 1963 the estimated population totaled 9,798,000, including 90,500 Indians and Pakistanis, 27,600 Arabs, and 22,700 Europeans. The Indians and Pakistanis are chiefly artisans and traders and nearly all live in the towns. The Arabs live mostly in the coastal areas, with a few in the Kigoma, Tabora, Dodoma, and Singida regions. The Swahili language (*q.v.*) is the lingua franca. The principal townships, with populations according to the 1957 census, are Dar es Salaam (128,742), Tanga (38,053), Mwanza (19,877), Tabora (15,361), Morogoro (14,507), Moshi (13,726), and Dodoma (13,435).

In the 1960s the African population was increasing at an average rate of nearly 2% annually, though in some of the highland tribes the increase was more rapid. The Asian communities had a higher rate of natural increase (about 2.5%).

#### B. ZANZIBAR

**1. Ethnography and Linguistics.**—The southern and eastern portions of Zanzibar Island are populated mainly by a Bantu-speaking people known as the Wahadimu (Hadimu); the northern portion of the island and adjacent Tumbatu are peopled by another Bantu-speaking people, the Watumbatu (Tumbatu). These two groups represent the earliest arrivals in Zanzibar. Throughout the 19th century, and after, they were expropriated from the western and more fertile parts of the island by later arrivals and still tend to keep aloof from the rest of the inhabitants. They are for the most part fishermen. Cattle raising was formerly one of their industries, but the herds have greatly diminished. Ropemaking (from coir) is carried on extensively by the Wahadimu women in the southern villages. The remainder of the population is of a very heterogeneous character, including Arabs, Europeans, Goans, Indians, and representatives of tribes from many parts of East Africa.

The aborigines of Pemba include the Watumbatu and Bantu-speaking Africans of mixed origins, who are known collectively and generically as Wapemba (Pemba). Pemba has evidence of 10th- to 16th-century Persian settlement, and the indigenous people

claim Persian affinity, calling themselves Shirazis.

The language most widely spoken is a highly arabicized form of Swahili. Bantu languages are spoken by the indigenous Wahadimu, Watumbatu, and Wapemba. Among the Arabs, the language of the home is usually Swahili, and the use of pure Arabic is confined to scholars and recent arrivals from Arabia. Indian languages are spoken by the Asian communities, and English and Swahili are widely used and understood.

The majority of the Arabs and Africans are orthodox Sunni Muslims, though a few of the older Arab families, including that of the former royal family, are of the Ibadi sect (*see KHARIJITES*). There are a few hundred Christian Africans. Among the Asians, Muslims are the most numerous. There are minorities of Hindus, Parsees, Buddhists, and Christians.

**2. Population Statistics.**—The 1958 census showed the population of Zanzibar Island to be 165,253, that of Pemba 133,858. About 76% of the inhabitants were Africans, 16% Arabs, and 6% Asians. Zanzibar City had a population of 57,923. The main townships in Pemba are Wete (pop. 7,507), Chake Chake (7,167), and Mkoani (1,977).

#### III. HISTORY

##### A. TANGANYIKA

**1. Early History and Exploration.**—Most of the known history of Tanganyika before the 19th century concerns the coastal area, although the interior has a number of important prehistoric sites, including the Olduvai Gorge (*see also the East African subsections of History and Archaeology in the article AFRICA*). Trading contacts between Arabia and the East African coast existed by the 1st century A.D., and there are indications of connections with India. The coastal trading centres were mainly Arab settlements, and relations between the Arabs and their African neighbours appear to have been fairly friendly. After the arrival of the Portuguese in the late 15th century, the position of the Arabs was gradually undermined, but the Portuguese made little attempt to penetrate into the interior. They lost their foothold north of the Ruvuma (Rovuma) River early in the 18th century as a result of an alliance between the coastal Arabs and the ruler of Muscat (on the Arabian Peninsula). This link remained extremely tenuous, however, until French interest in the slave trade from the ancient town of Kilwa, on the Tanganyikan coast, revived the trade in 1776. Attention by the French also aroused the sultan of Muscat's interest in the economic possibilities of the East African

coast, and a new Omani governor was appointed at Kilwa. For some time most of the slaves came from the Kilwa hinterland, and until the 19th century such contacts as existed between the coast and the interior were due mainly to African caravans from the interior.

In their constant search for slaves, Arab traders began to penetrate farther into the interior, more particularly in the southeast toward Lake Nyasa. Farther north two merchants from India followed the tribal trade routes to reach the country of the Nyamwezi about 1825. Along this route ivory appears to have been as great an attraction as slaves, and Sayyid Sa'id ibn Sultan himself (see below, *Zanzibar*), after the transfer of his capital from Muscat to Zanzibar gave every encouragement to the Arabs to pursue these trading possibilities. From the Nyamwezi country the Arabs pressed on to Lake Tanganyika in the early 1840s. Tabora (or Kazé, as it was then called) and Ujiji, on Lake Tanganyika, became important trading centres, and a number of Arabs made their homes there. They did not annex these territories but occasionally ejected hostile chieftains. Mirambo, an African chief who built for himself a temporary empire to the west of Tabora in the 1860s and 1870s, effectively blocked the Arab trade routes when they refused to pay him tribute. His empire was purely a personal one, however, and collapsed on his death in 1884.

The first Europeans to show an interest in Tanganyika in the 19th century were missionaries of the Church Missionary Society, J. L. Krapf and J. Rebmann, who in the late 1840s discovered Mt. Kilimanjaro. It was a fellow missionary, J. Erhardt, whose famous "slug" map (showing, on Arab information, a vast, shapeless, inland lake) helped stimulate the interest of the British explorers Richard (later Sir Richard) Burton and John Hanning Speke. They traveled from Bagamoyo to Lake Tanganyika in 1857-58, and Speke also saw Lake Victoria. This expedition was followed by Speke's second journey in 1860, in the company of J. A. Grant, to justify the former's claim that the Nile rose in Lake Victoria. These primarily geographical explorations were followed by the activities of David Livingstone, who in 1866 set out on his last journey for Lake Nyasa. Livingstone's object was to expose the horrors of the slave trade and, by opening up legitimate trade with the interior, to destroy the slave trade at its roots. Livingstone's journey led to the later expeditions of H. M. Stanley and V. L. Cameron. Spurred on by Livingstone's work and example, a number of missionary societies began to take an interest in East Africa after 1860.

**2. German Ascendancy.**—It was left to Germany, with its newly awakened interest in colonial expansion, to open up the country to European influences. The first agent of German imperialism was Karl Peters, who, with Count Joachim Pfeil and Karl Juhlke, evaded the sultan of Zanzibar late in 1884 to land on the mainland. He made a number of "contracts" in the Usambara area by which several chiefs were said to have surrendered their territory to him. Peters' activities were confirmed by Bismarck. By the Anglo-German Agreement of 1886 the sultan of Zanzibar's vaguely substantiated claims to dominion on the mainland were limited to a ten-mile-wide coastal strip, and Britain and Germany divided the hinterland between them as spheres of influence, Germany taking the region later known as Tanganyika. Following the example of the British to the north, the Germans obtained a lease of the coastal strip from the sultan in 1888, but their tactlessness, and fear of commercial competition, led to a Muslim rising in August 1888. The rebellion was put down only after the intervention of the imperial German government and with the assistance of the British Navy.

Recognizing the administrative inability of the German East Africa Company, which had hitherto ruled the country, the German government declared a protectorate over its sphere of influence in 1891 and over the coastal strip, where the company had bought out the sultan's rights. Germany was anxious to exploit the resources of its new dependency, but lack of communications at first restricted development to the coastal area. The introduction of sisal from Florida in 1892 by the German agronomist Richard Hindorff marked the beginning of the territory's most valuable industry, which was encouraged by the development of

a railway from the new capital of Dar es Salaam to Lake Tanganyika. In 1896 work began on the construction of a railway running northwestward from Tanga to Moshi, which it reached in 1912. This successfully encouraged the pioneer coffee-growing activities on the slopes of Mt. Kilimanjaro. Wild rubber tapped by Africans, together with plantation-grown rubber, helped swell the country's economy. The government also supplied good-quality cotton seed free to African growers and sold it cheaply to European planters. The administration also tried to make good the lack of clerks and minor craftsmen by encouraging the development of schools, an activity in which various missionary societies were already engaged.

The enforcement of German overlordship was strongly resisted, but control was established by the beginning of the 20th century. Almost at once came a reaction to German methods of administration, the outbreak of the Maji Maji rising in 1905. Although there was little organization behind it, the rising spread over a considerable portion of southeastern Tanganyika and was not finally suppressed until 1907. It led to a reappraisal of German policy in East Africa. The imperial government had attempted to protect African land rights in 1895 but had failed in its objective in the Kilimanjaro area. Similarly, liberal labour legislation had not been properly implemented. The German government set up a separate Colonial Department in 1907, and more money was invested in East Africa. A more liberal form of administration rapidly replaced the previous semimilitary system.

World War I put an end to all German experiments. Blockaded by the British Navy, the country could neither export produce nor get help from Germany. The British advance into German territory continued steadily from 1916 until the whole country was eventually occupied. The effects of the war upon Germany's achievements in East Africa were disastrous; the administration and economy were completely disrupted. In these circumstances the Africans reverted to their old social systems and their old form of subsistence farming. Under the Treaty of Versailles (1919) the U.K. received a League of Nations mandate to administer the territory except for Ruanda-Urundi, which came under Belgian administration, and the Kionga triangle, which went to Portugal.

**3. British Mandate.**—Sir Horace Byatt, administrator of the captured territory and, from 1920 to 1924, first British governor and commander in chief of Tanganyika Territory (as it was then renamed; all the territory under German control had been called German East Africa), enforced a period of recuperation before new development plans were set on foot. A Land Ordinance (1923) ensured that African land rights were secure. Sir Donald Cameron, governor from 1925 to 1931, infused new vigour into the country. He reorganized the system of native administration by the Native Authority Ordinance (1926) and the Native Courts Ordinance (1929). His object was to build up local government on the basis of traditional authorities, an aim that he pursued with doctrinaire enthusiasm and success. He attempted to silence the criticisms by Europeans that had been leveled against his predecessor by urging the creation of a Legislative Council in 1926 with a reasonable number of nonofficial members, both European and Asian. In his campaign to develop the country's economy, Cameron won a victory over opposition from Kenya by gaining the British government's approval for an extension of the Central Railway Line from Tabora to Mwanza (1928). His attitude toward European settlers was determined by their potential contribution to the country's economy. He was, therefore, surprised by the British government's reluctance to permit settlement in Tanganyika. The economic depression after 1929 resulted in the curtailment of many of Cameron's development proposals. In the 1930s, too, Tanganyika was hampered by fears that it might be handed back to Germany in response to Hitler's demands for overseas possessions.

At the outbreak of World War II Tanganyika's main task was to make itself as independent as possible of imported goods. Inevitably the retrenchment evident in the 1930s became still more severe, and, while prices for primary products soared, the value of money depreciated proportionately. Tanganyika's main objective after the war was to ensure that its program for economic recovery

and development should go ahead. The continuing demand for primary produce strengthened the country's financial position. The chief item in the development program was a plan to devote 3,000,000 ac. (1,200,000 ha.) of land to the production of peanuts (the Groundnuts Scheme). The plan, which was to be financed by the British government, was to cost £25,000,000, and, in addition, a further £4,500,000 would be required for the construction of a railway in southern Tanganyika. It failed because of the lack of adequate preliminary investigations and was subsequently carried out on a greatly reduced scale.

**4. Constitutional Progress and Independence.**—Constitutionally, the most important immediate postwar development was the British government's decision to place Tanganyika under UN trusteeship (1947). Under the terms of the trusteeship agreement, Britain was called upon to develop the political life of the territory, which, however, only gradually began to take shape in the 1950s with the growth of the Tanganyika African National Union (TANU). The first two African members had been nominated to the Legislative Council in December 1945. This number was subsequently increased to four, with three Asian unofficial members and four Europeans. An official majority was retained. In an important advance in 1955, the three races were given parity of representation on the unofficial side of the council with ten nominated members each, and for a time it seemed as if this basis would persist. The first elections to the unofficial side of the council, however, enabled TANU to show its strength, for even among the European and Asian candidates only those supported by TANU were elected.

A constitutional committee in 1959 unanimously recommended that after the elections, in 1960, a large majority of the members of both sides of the council should be Africans and that elected members should form the basis of the government. The approval of the British colonial secretary was obtained for these proposals in December 1959, and in September 1960 a predominantly TANU government took office. The emergence of this party and its triumph over the political apathy of the people were largely due to the leadership of Julius Nyerere (*q.v.*). Tanganyika became independent in December 1961, with Nyerere as its first prime minister. The November 1962 elections for the country's first president under a republican constitution resulted in an overwhelming victory for Nyerere. On Dec. 9, 1962, the anniversary of its independence, Tanganyika became a republic within the Commonwealth. (For later history see *Tanzania* below.)

## B. ZANZIBAR

The history of Zanzibar has been to a large extent shaped by the monsoons (prevailing trade winds); and by its proximity to the continent. The regular annual recurrence of the monsoons has made possible its close connection with India and the countries bordering the Red Sea and the Persian Gulf. Its proximity to the continent has made it a suitable jumping-off point for trading and exploring ventures not only along the coast but also into the interior.

**1. Early History and Portuguese and Omani Domination.**—Though the first references to Zanzibar occur only after the rise of Islam, there would appear to be little doubt that its close connection with southern Arabia and the countries bordering the Persian Gulf began before the Christian era. At the beginning of the 13th century, the Arab geographer Yakut recorded that the people of Lenguja (*viz.*, Unguja, the Swahili name for Zanzibar) had taken refuge from their enemies on Tumbatu, the inhabitants of which were Muslims.

In 1498 Vasco da Gama visited Malindi, and in 1503 Zanzibar Island was attacked and made tributary by the Portuguese. It appears to have remained in that condition for about a quarter of a century. Thereafter the relations between the rulers of Zanzibar and the Portuguese seem to have been those of allies, the people of Zanzibar more than once cooperating with the Portuguese in attacks upon Mombasa. In 1571 the "king" of Zanzibar, in gratitude for Portuguese assistance in expelling certain African invaders, donated the island to his allies, but the donation was never implemented. A Portuguese trading factory and an Augustinian

mission were established on the site of the modern city of Zanzibar, and a few Portuguese appear also to have settled as farmers in different parts of the island. The first English ship to visit Zanzibar (1591–92) was the "Edward Bonaventure" captained by Sir James Lancaster.

When the Arabs captured Mombasa in 1698 all these settlements were abandoned and (except for a brief Portuguese reoccupation in 1728) Zanzibar and Pemba came under the domination of the Arab rulers of Oman. For more than a century those rulers left the government of Zanzibar to local hakims (governors). The first sultan to take up residence in Zanzibar was Sayyid Sa'id ibn Sultan (*see* SA'ID IBN SULTAN), who after several short visits settled there soon after 1830 and subsequently greatly extended his influence along the East African coast. On Sa'id's death in 1856 his son Majid succeeded to his African dominions, while another son, Thuwaini, succeeded to Oman (*see also* MUSCAT AND OMAN).

As the result of an award made in 1860 by Lord Canning, governor general of India, the former African dominions of Sa'id were declared to be independent of Oman. Majid died in 1870 and was succeeded by his brother Barghash (Burgash). Toward the end of the latter's reign his claims to dominion on the mainland were restricted by Britain, France, and Germany to a 10-mi. (16 km.)-wide coastal strip, the administration of which was subsequently shared by Germany and Britain (*see above, Tanganyika*). Barghash died in 1888. Both he and Majid had acted largely under the influence of Sir John Kirk (*q.v.*), who was British consular representative at Zanzibar from 1866 to 1887. It was by Kirk's efforts that Barghash consented in 1873 to a treaty for the suppression of the slave trade.

**2. British Protectorate.**—In 1890 what was left of the sultanate was proclaimed a British protectorate, and in 1891 a constitutional government was instituted under British auspices with Sir Lloyd Mathews as first minister. In August 1896, on the death of the ruling sultan, Hamad ibn Thuwaini, the royal palace at Zanzibar was seized by Khalid, a son of Sultan Barghash, who proclaimed himself sultan. The British government disapproved, and, as he refused to submit, the palace was bombarded by British warships. Khalid escaped and took refuge at the German consulate, whence he was conveyed to German East Africa. Hamud ibn Mohammed was then installed as sultan (Aug. 27, 1896). In 1897 the legal status of slavery was finally abolished. In 1913 the control of the protectorate passed from the Foreign Office to the Colonial Office, when the posts of consul general and first minister were merged into that of British resident. At the same time a Protectorate Council was constituted as an advisory body. In 1926 the advisory council was replaced by nominated executive and legislative councils.

Khalifa ibn Harub became sultan in 1911. He was the leading Muslim prince in East Africa, and his moderating influence did much to steady Muslim opinion in that part of Africa at times of political crisis, especially during the two world wars. He died on Oct. 9, 1960, and was succeeded by his eldest son, Sir Abdullah ibn Khalifa.

**3. Progress Toward Independence.**—In November 1960 the British Parliament approved a new constitution for Zanzibar. The first elections to the Legislative Council then established were held in January 1961 and ended in a deadlock. Further elections, held in June, were marked by serious rioting and heavy casualties. As a result of the elections ten seats were won by the Afro-Shirazi Party (ASP), representing mainly the African population; ten by the Zanzibar Nationalist Party (ZNP), representing mainly the Zanzibari Arabs; and three by the Zanzibar and Pemba People's Party (ZPPP), an offshoot of the ZNP. The ZNP and ZPPP combined to form a government with Mohammed Shamte Hamadi as chief minister.

A constitutional conference held in London in 1962 was unable to fix a date for the introduction of internal self-government or for independence because of failure to agree on franchise qualifications, the number of elected seats in the legislature, and the timing of the elections. However, an independent commission subsequently delimited new constituencies and recommended an increase in the numbers of the Legislative Council, which the council ac-

cepted, also agreeing to the introduction of universal adult suffrage. Internal self-government was established in June 1963, and elections held the following month resulted in a victory for the ZNP-ZPPP coalition, which won 18 seats, the ASP winning the remaining 13. Final arrangements for independence were made at a conference in London in September. In October it was agreed that the Kenya coastal strip—a territory that extended 10 mi. inland along the Kenya coast from the Tanganyika frontier to Kipini and that had long been administered by Kenya although nominally under the sovereignty of the sultans of Zanzibar—would become an integral part of Kenya on that country's attainment of independence.

On Dec. 10, 1963, Zanzibar achieved independence as a member of the Commonwealth. In January 1964 the Zanzibar government was overthrown by an internal revolution, Sayyid Jamshid ibn Abdullah (who had succeeded to the sultanate in July 1963 on his father's death) was deposed, and a republic was proclaimed.

Although the revolution was carried out by only about 600 armed men under the leadership of the Communist-trained "Field Marshal" John Okello, it won considerable support from the African population; this was demonstrated when Sheikh Abeid Amani Karume, leader of the Afro-Shirazi Party, was installed as president of the "People's Republic of Zanzibar and Pemba." Sheikh Abdulla Kassim Hanga was appointed prime minister, and Abdul Rahman Mohammed ("Babu"), leader of the new left-wing Umma ("The Masses") Party (formed by defectors from the ZNP), became minister for defense and external affairs. Pending the establishment of a new constitution, the cabinet and all government departments were placed under the control of a Revolutionary Council of 30 members, which was also vested with temporary legislative powers. Zanzibar was proclaimed a one-party state.

The revolution was marked by acts of violence against Arabs and Asians; members of these communities later left Zanzibar in considerable numbers. Measures taken by the new government included the nationalization of all land, with further powers to confiscate any immovable property without compensation except in cases of undue hardship. (For later history see *Tanzania* below.)

### C. TANZANIA

By an act of union signed by their presidents, the Republic of Tanganyika and the People's Republic of Zanzibar became one state on April 27, 1964, at first called the Republic of Tanganyika and Zanzibar, renamed the United Republic of Tanzania on Oct. 29. Nyerere became president and Karume first vice-president. The cabinet included both Zanzibari and Tanganyikan ministers. The two countries, however, retained many of their individual characteristics, and Zanzibar did not take part in the first post-independence general elections, held in September 1965 on the basis of a new one-party constitution. Instead the members of the Revolutionary Council became members of the Tanzania National Assembly. Meanwhile in Tanganyika, to ensure a democratically elected government, voters in each constituency were able to choose between two TANU candidates. The efficacy of this method was evident when only six candidates were returned unopposed and several former ministers lost their seats. Nyerere was unanimously reelected president.

President Nyerere announced a five-year economic and social development plan in May 1964. In the economic field his aim was to make Tanzania less dependent upon foreign imports, and to do this numerous processing industries were developed, including seven textile mills, an oil refinery, and four factories for processing sisal. To help in these plans, loans were accepted from several countries, among them China, the U.S.S.R., the German Federal Republic, the German Democratic Republic, and Britain. This led to accusations from Western sources that Tanzania was becoming too closely associated with the Eastern powers, a view which was strengthened, though not justified, when Tanzania broke off diplomatic relations with Britain in December 1965 on Rhodesia's unilateral declaration of independence (see RHODESIA). Nyerere denied having pro-Communist sympathies and maintained that his country's role was one of nonalignment.

In February 1967 Nyerere announced the nationalization of all commercial banks, insurance companies, most of the flour milling industry, and the major wholesale trading companies. The government also took a majority share in seven other companies. All were promised full and fair compensation and employees were urged to stay on as civil servants.

## IV. ADMINISTRATION AND SOCIAL CONDITIONS

**1. Constitution and Government.**—The United Republic of Tanzania came into being as the result of an agreement between the presidents of Tanganyika and Zanzibar, which was later ratified by the legislatures of the two countries. Under the terms of the agreement a Constituent Assembly was to be summoned not later than April 26, 1965, until which time the united republic would adopt the constitution of Tanganyika modified to provide for a local legislature and executive in Zanzibar. Tanganyika at once ceased to have a separate government, but Zanzibar retained its Revolutionary Council and its own government. The meeting of the Constituent Assembly was delayed a further year pending the implementation of an interim constitution, which was approved on July 5, 1965. The summoning of the Constituent Assembly being indefinitely postponed, the interim constitution remained in force. It provided for a one-party state and envisaged the ultimate merger of the Tanganyikan TANU and Zanzibari ASP parties.

Under the constitution the president is the chief executive officer, holding office for five years. He is nominated by TANU and ASP acting together, and his nomination must be ratified by a plebiscite of the whole electorate of Tanganyika and Zanzibar at the time of elections to the National Assembly, though by a separate vote. Such a plebiscite took place in September 1965. The president is empowered to appoint two vice-presidents, who, together with a number of ministers, comprise the cabinet; this is presided over by the president himself. The assent of the president is required before any bill passed by the National Assembly becomes law. If he withholds his assent and the bill is again passed by the assembly with a two-thirds majority, he must give his assent within 21 days or dissolve the assembly. The dissolution of the assembly also involves a new election to the presidency. The assembly consists of a maximum of 204 members, of whom 55 may represent Zanzibar; the president may nominate ten members. Under the terms of the interim constitution, voters in each constituency may choose between two candidates selected by the National Executive Committee of the party; these are selected from among those party members who have submitted themselves for consideration with the support of 25 people from their constituency. The Tanganyika members of the National Assembly were elected in this way in September 1965. No elections to the assembly were held in Zanzibar, and the Zanzibar seats were held by the members of the Revolutionary Council.

By the beginning of 1967 the union between the two republics was far from complete. The original act of union provided for a local legislature and executive for Zanzibar dealing with internal affairs and having limited powers. In fact, the Revolutionary Council continued to deal with foreign governments and with many other aspects of government which might seem to fall pre-eminently within the scope of the union government. On May 11, 1965, the Revolutionary Council approved a new constitution for Zanzibar making the ASP the supreme authority and declaring all other parties illegal. A central committee of the ASP was set up headed by the president of the party, and other committees were appointed to control education, finance, security, and other aspects of administration. The ministers were said to serve the party rather than the government, but the Revolutionary Council continued to exercise final power and to legislate by decree.

**Local Government.**—Tanganyika is divided into 17 regions under the direction of regional commissioners, political officers similar to junior ministers who sit in the National Assembly. This arrangement assists in the efficient operation of the National Development Corporation, established on Jan. 1, 1965, as the regional commissioners act as an interested link between the Ministry of Economic Affairs and Development on the one hand and the

regional and area committee directly concerned with local developments on the other. Local government is concerned with such matters as primary education, agriculture, marketing, and health.

**Common Services.**—Tanzania is a member of the East African Common Services Organization, an interterritorial body, successor to the East Africa High Commission, administering certain common services including railways and harbour services, postal services, telecommunications, and customs, although each country is autonomous in fixing its customs duties. Under the terms of the Kampala Agreement signed by the three territories (Tanzania, Uganda, and Kenya) in April 1964 an attempt was made to eliminate the former imbalance of trade and to secure a more equitable distribution of industrial development.

**2. Living Conditions.**—In the later 1960s the population was growing at the rate of approximately 2% yearly and over 40% of the population was under the age of 15. Almost 5,500,000 people were of working age and (in 1963) 366,000 were in paid employment, the rest being mainly engaged in cultivating tribal land.

The number of paid employees fell between 1961 and 1963 owing, in part, to the introduction of minimum wage legislation in 1962. The average annual per capita income in 1963 was £24 (\$67), near the average for East Africa; the cost of living, even in Dar es Salaam, remained fairly constant between 1960 and 1966. In 1964 trade unions in Tanganyika were dissolved by law and replaced by one National Union of Tanganyika Workers (NUTA). The general and deputy secretary of the union were appointed by the president, and the government planned, through the union, to link annual wage increases with productivity. In Zanzibar the Federation of Revolutionary Trade Unions was abolished in 1965 and its affairs were taken over by a special labour committee of the ASP. Farms and business concerns owned by non-Africans were nationalized, and an attempt was being made to introduce a national insurance scheme on the island.

**3. Health and Welfare.**—In the 1960s the government, missions, and local authorities maintained more than 800 maternity and child-health clinics in Tanganyika, together with about 250 hospitals with 15,000 beds, about 20 major leprosariums, and more than 1,000 outpatient dispensaries. The commonest diseases included malaria, sleeping sickness, smallpox, and leprosy. In Zanzibar medical services were nationalized and free.

**4. Justice.**—There is a High Court for the united republic with final jurisdiction in both criminal and civil cases, composed of a chief justice appointed by the president and of lesser judges appointed by the president after consultation with the chief justice. Subordinate courts have limited jurisdiction in each district. In November 1964 the Ministry of Justice was dissolved and its functions were transferred to the second vice-president. In Zanzibar a decree of Oct. 28, 1966, set up a secret court to try political offenders; it was suspended in December. The court would not have been bound by normal rules of criminal procedure.

**5. Education.**—Tanzania's five-year development plan (1964-69), included considerable provision for education, in the hope of making good the serious shortage of skilled and professional work-

ers. About half the children of Tanganyika (500,000) attend the four-year course in the lower primary schools. Only one-sixth go on to the upper primary schools, and no more than 4% (20,000) enter the secondary schools or take craft courses. Trade courses are provided in residential government schools at Moshi and Ifunda and in a number of other voluntary centres. A technical college in Dar es Salaam provides advanced trade school courses and three-year courses for technicians. The University College of Dar es Salaam, part of the federal University of East Africa (founded 1963), has faculties of arts, science, law, and social sciences. In 1964-65 some 450 students from Tanzania were attending courses at the university, with many more in universities overseas. Considerable attention is paid to adult education, with literacy campaigns and courses for women in domestic economy and hygiene; more than 1,500 students attend evening classes at the technical college in Dar es Salaam. Several companies, including the Williamson Diamond Mines and the East African Railways and Harbours Board, run their own training projects. In the primary schools Swahili is the language of instruction, but English is introduced in the third year and becomes the normal teaching medium in middle schools. There are plans for expansion at all levels of education, but particularly in teacher training, by 1970. More than one-tenth of government expenditure, £4,000,000 (\$11,200,000), is spent annually on education.

In Zanzibar schools have been nationalized and education is free, although very limited. Primary school places, only 3,000 in 1964, were increased to 7,500 in 1966, and agriculture and handicrafts were introduced into the curriculum. Secondary education is available only on a very limited scale, and the proportion of secondary to primary places is to remain static for the time being.

**6. Defense.**—A mutiny occurred in the Tanganyika army in January 1964; as a result, the two battalions of the Tanganyika Rifles were disbanded. Three completely new battalions, the Tanzanian People's Defense Force, were then raised, and it was planned that they should be organized on nontraditional lines.

VIEWS OF THE CITY OF ZANZIBAR: (TOP LEFT) PALACE OF THE FORMER SULTANS OVERLOOKS THE HARBOUR. (ABOVE RIGHT) NARROW THOROUGHFARE LINED WITH WHITEWASHED HOUSES. BARRED LOWER WINDOWS PROTECTED THE INHABITANTS FROM PIRATES PARADING THE STREETS AS LATE AS THE MID-19TH CENTURY. (ABOVE LEFT) A TOWER OF THE OLD ARAB FORT ON THE WATERFRONT, NOW USED AS A WOMEN'S CLUB

About half the personnel would consist of volunteers from the National Youth Service combining two years' military duty with public works and village development projects. By a presidential decree of Oct. 5, 1964, the People's Liberation Army of Zanzibar was incorporated into the armed forces of the union republic as a further battalion of the Tanzanian People's Defense Force; it continued to act with a considerable degree of independence, however, and was trained by Chinese instructors. (K. I.)

## V. THE ECONOMY

### A. TANGANYIKA

Agriculture dominates the economy, accounting for about 80% of the exports by value. There is an important livestock industry, and mining production is considerable.

**1. Agriculture and Forestry.**—Sisal, introduced in 1892, is the most important product. By 1914 production reached 20,000 tons of fibre annually and by the mid-1960s was approaching 250,000 tons. Pyrethrum, tobacco, and wheat are grown in the upland areas; grains (maize [corn], millet, sorghum, rice), cotton, cocoa, pulses, peanuts, and oilseeds in the higher rainfall areas of the plains; and coconuts, cassava, cashew nuts, and citrus fruits in the coastal belt. The principal subsistence crops are rice, maize, cassava, sorghum, bananas, and pulses. Irrigation projects have been developed in central Tanganyika and in the Rufiji and Mbarali river basins. Sugar production near Moshi and in the Kilombero Valley was expanding; it reached 50,000 tons in the mid-1960s. In the drier plains pastoral tribes herd cattle, sheep, and goats, but tsetse infestation hinders the livestock industry. Meat production is increasing, however, and government cattle ranches have been developed. Areas of true forest are limited, but valuable timbers include muninga, camphor, muvule, and African mahoganies and blackwood. The cooperative movement is widespread, and the value of produce handled is about 25% of the total value of exports.

**2. Mining.**—Diamonds account for about two-thirds by value of Tanganyika's mineral output. Diamondiferous deposits around Shinyanga, south of Lake Victoria, were discovered in 1940 by J. T. Williamson, and by the mid-1960s the mine at Mwadui (in which the government acquired a half share) was producing more than 600,000 k. annually. Gold (about £1,200,000 annually), salt, silver, mica, and tin are among mining products. Immense deposits of iron ore and coal exist in the southwest near Lake Nyasa but are difficult of access. At least 190,000,000 tons of coal are estimated as minable. Production in the mid-1960s reached about 3,000 tons.

**3. Power and Industries.**—Electric power generation and supply are carried out by a company with an exclusive franchise. Major hydroelectric installations include one at Pangani Falls (17.5 megawatts) and the Hale Station on the Pangani River (21.5 Mw.). The latter, completed in 1964, has a transmission line to serve Dar es Salaam with virtually all its needs, and 33-kw. lines run east from Hale to Tanga and other coastal sites and west to Korogwe and Lushoto. Other main thermal power stations are at Tanga, Dar es Salaam, Arusha, Moshi, and Mwanza.

Manufacturing industries are mostly connected with agricultural and forest products (food, flour, and sisal processing, oil, and saw-milling) but include the production of textiles, clothing, cans, paint, and soap for local consumption, as well as soft drinks, beer, cigarettes, aluminum ware, bricks and tiles, coir and sisal matting, leather, cement, industrial gases, and shoes. By the 1960s manufacturing contributed about 4% of the gross domestic product.

**4. Trade.**—About 50% of Tanganyika's gross domestic product derives from agriculture, and the economy is therefore sensitive to changes in the prices of export products, notably sisal. Total exports (including those to Kenya and Uganda and re-exports) reached £65,000,000 (\$182,000,000) in 1963, about one-quarter being taken by the U.K. and about one-fifth by other Commonwealth countries. Exports in order of value were sisal, cotton, coffee, diamonds, oilseeds, cashew nuts, meat and meat extracts, hides and skins, tea, gold, and pyrethrum. Imports (mainly textiles, vehicles and transport equipment, petroleum fuels, iron and steel, machinery, chemicals, and foodstuffs) included substantial

quantities of local produce from Kenya and Uganda and totaled about £40,000,000 (\$112,000,000) annually, more than one-third coming from the U.K.

**5. Finance.**—Most of Tanganyika's recurrent revenue is derived from income and personal taxes, local government rates, company taxes, customs and excise duties, and income from government properties. Among the main items of expenditure are education, communications, power, public works, police, agriculture, health, and labour. The currency is based on the East African shilling, which is legal tender for any amount and is subdivided into 100 cents. Tanzan Shs. 20 = Tanzan £1, the latter being at par with the U.K. pound sterling (= \$2.80 U.S.). The Directorate of Development and Planning was set up to implement Tanzania's five-year development plan announced in 1964.

In February 1967 nationalization of foreign banks, insurance firms, leading trading companies, and sisal estates followed a declared aim of bringing principal means of production under government control.

**6. Transport and Communications.**—The railways form part of the East African Railways and Harbours System. There are three main lines, all of metre gauge. Tanganyika has about 21,500 mi. (34,500 km.) of roads, 3,900 mi. (6,200 km.) of which were classed as all-weather (1962). Main roads are from Dar es Salaam and Tanga inland and the north-south link from Nairobi in Kenya.

The East African Railways and Harbours Administration operates passenger and freight road services, and there are widespread local bus and truck services. More than 20 shipping lines operate services to Tanganyika, some calling at Tanga and Mtwara, as well as at Dar es Salaam. There are passenger and cargo services on Lakes Victoria, Tanganyika, and Nyasa. East African Airways Corporation operates internal scheduled flights and services to the U.K., South Africa, India, and Pakistan; other airlines maintain links with adjoining territories. There is the usual range of postal services but no house-to-house delivery by postmen, the box or private bag system being used. Scheduled air services are widely used for mail transport. There were 70 telephone exchanges in Tanganyika in 1966, 7 of which were fully automatic. Radio broadcasting is controlled by a corporation directed by a government-nominated board and emanates from Dar es Salaam, with a national program in Swahili and a second program in English and Asian languages. (J. P. Mt.; J. M. Ke.)

### B. ZANZIBAR

Prior to the development of East African mainland ports Zanzibar was the trade focus of this region and enjoyed an important entrepôt trade. The economy now depends on agriculture and fishing.

**1. Agriculture and Forestry.**—Considerable areas of fertile soil and a favourable climate make possible the production of a variety of tropical crops under plantation and peasant conditions. Following the revolution of 1964, land previously held by Arabs, Indians, and Africans was nationalized. Immigrant Africans still play an important part in plantation work.

The Zanzibari clove industry owes its development to Sa'id ibn Sultan. About 80,000 ac. are planted to cloves, and annual production averages about 11,000 tons (though there are great seasonal variations of crop), more than 75% from Pemba. The Clove Growers' Association was nationalized in October 1964.

Coconuts occupy about 160,000 ac., mostly on the island of Zanzibar. Copra, coconut oil, coir fibre, and rope are all important products of the industry, which also produces food, thatching, and basket materials. Other less important export crops are chilies, fresh fruits, tobacco, and kapok. The government has actively encouraged diversification of agriculture in order to reduce its dependence on cloves, and experiment and trial over many years have been conducted in the production of chilies, limes (for oil and juice), cacao, derris, and other crops.

Among local food crops, rice is the main cereal; cassava and sweet potatoes are widely grown; pulses and vegetables are minor crops. Tropical fruits grow exceptionally well (citrus, pineapple, mango, pawpaw).

The livestock industry is relatively small and is actively encouraged. Cattle are of the African humped zebu type, except for small herds of European-grade cattle kept in the town dairies.

Three small natural forests occur, and mangrove swamps contain species of economic importance. These are reserved and exploitation and replanting controlled. Most products are used locally, though there are exports of mangrove bark (for tannin) and timber from Jozani Forest in Zanzibar.

**2. Fisheries.**—Fish is an important part of the diet, and local fisheries employ about one-tenth of the population. Basket traps, seine, gill, and cast nets, and hand lines are used from local boats and canoes in the shallow waters round the islands. An East African Marine Fisheries Research unit is based in Zanzibar, and the fishing industry is actively encouraged to adopt modern equipment.

**3. Power and Industries.**—No exploitable mineral resources occur. A fine building lime is made by burning coral limestone, but this is strictly limited by local fuel supplies. Wood is the principal domestic fuel; a diesel plant supplies electricity to Zanzibar City. Small secondary industries have developed for processing agricultural products: a clove-oil distillery, coir extraction plants, and coconut oil and soap factories. Local handicrafts include mat and basket weaving, coir ropemaking, pottery making, and canoe and boat building. A few Indian silversmiths work in Zanzibar City.

**4. Trade.**—Internal trade is largely in the hands of Indian merchants and shopkeepers. Imports (more than half of which came from the U.K. and the Commonwealth) in the mid-1960s were valued at about £5,000,000, principally foodstuffs and textiles; domestic exports (chiefly to India and Indonesia) were £3,500,000, of which cloves and clove products made up more than 70%.

**5. Finance.**—The East African shilling (*see above*) replaced the Indian rupee as standard currency in 1936. Government revenue in the early 1960s was about £3,000,000 and expenditure was similar. Principal items of taxation are import duties, export duties on cloves and coconut products, and income tax. No poll or hut taxes exist.

**6. Transport and Communications.**—There is no railway. Of the 387 mi. (623 km.) of roads in Zanzibar, about 280 mi. (450 km.) were bitumen surfaced in the 1960s. Pemba had about 225 mi. (365 km.), of which 80 mi. (130 km.) were bitumenized. Frequent services link Zanzibar airport (one all-weather runway) with East African airports. There is also an all-weather runway at Pemba airport, near Chake Chake. Zanzibar port is served by British, other European, and U.S. shipping companies, and the government maintains a service with Pemba and the mainland. There are also passenger and cargo coasting vessels linking Zanzibar and the ports of Kenya and Tanganyika.

Normal postal services are maintained and savings-bank facilities provided. There is continuous service by direct cable, radio, and radiotelephone to East and southern Africa, Aden, Seychelles, and London. Internal telephone systems operate in both islands. The broadcasting station is at Marahubi Mlangoni from where Cable and Wireless, Ltd., operates the government's medium-wave and its own short-wave transmission services.

**T'AO CH'EN** (T'AO YUAN-MING) (c. 365-427), Chinese poet, regarded by modern critics as the most important of his period, was born into a gentry family that had fallen on hard times. When he was about 20, he took a minor official post and for the next ten years was in the service of one or another of the ambitious generals who were threatening the moribund Chin dynasty. In 405, after a brief term as magistrate of P'engts'e, he retired from public life to make a precarious living as a farmer. On more than one occasion crop failure brought him and his family to the verge of starvation. On leaving his last post, he had written, "My instinct is all for freedom and will not brook discipline or restraint. Hunger and cold may be sharp, but this going against myself really sickens me. Whenever I have been involved in official life I was mortgaging myself to my mouth and belly." He had no more dealings with officialdom but stuck to the life of poverty and hardship, which he preferred to the rigours of respectability. At the time of his death he was known chiefly as a recluse and an eccentric.

T'ao Ch'ien's poetry was not much appreciated before the 8th century. The taste of his contemporaries was for an elaborate and artificial style, and his poetry is simple and straightforward, with a minimum of artifice. It deals with country pursuits and his essentially Taoist philosophy of life and death.

*T'ao the Hermit: Sixty Poems* was translated and annotated with an introduction by William Acker (1952); *Poems* was translated by Lily Pao-hu Chang and Marjorie Sinclair (1953). *See also CHINESE LITERATURE: The Six Dynasties and the Sui Period.*

(J. R. Hr.)

**TAOISM** has been an integral part of Chinese life and thought for 2,000 years. Like Confucianism (*q.v.*), it has influenced every aspect of Chinese culture, whether philosophy, religion, art, literature, or government. Throughout Chinese history, it has paralleled Confucianism, reinforcing, supplementing, and criticizing it, and it helped shape the development and transformation of Buddhism in China. In a true sense every Chinese is a Taoist. While Confucianism emphasizes social order and an active life, Taoism concentrates on individual life and tranquillity. Though this suggests that Taoism plays a secondary role, the fact is that in its advocacy of individuality, spiritual freedom, naturalness, simplicity, religious mysticism, *laissez faire* in government, and the transcendental ideal in art, it is as important as Confucianism in Chinese tradition.

The name "Taoist School" was not mentioned until the 1st century B.C., but the movement must have been developing for centuries before that. Tradition says that ancient philosophical schools emerged from government offices, and Taoism in particular from that of the historian. This theory may have been influenced by the fact that Lao-tzu, traditionally considered to be the founder of Taoism, was a curator of historical documents. The deeper meaning of the theory, however, is that Taoism arose in response to actual historical situations. In the 6th century B.C. feudalism in China was beginning to crumble. In the transition to a new age, society was beset with political disorder, economic chaos, and moral decay. For several centuries each of the "100 schools" of philosophy offered its own *tao* (literally, "way") as a solution. The *tao* offered by Lao-tzu and his followers was so unusual and so challenging that their movement alone came to be known as the Taoist School, *Tao-chia*.

Taoism is not a system of purely quiet contemplation or idle speculation. It is a philosophy offering a practical way of life. Later its teachings came to be utilized in the popular religion called *Tao-chiao*. In the Chinese tradition the two have been separate, but in the West they have often been confused under the name Taoism.

## PHILOSOPHICAL TAOISM

The origin of Taoism as a philosophy is obscure. The term *tao* can be traced to the earliest Chinese classics, and it is a basic term in all ancient Chinese philosophical schools, including Confucianism. But it was in Lao-tzu, Yang Chu, Chuang-tzu, the *Huai-nan-tzu*, the Neo-Taoists, and the *Lieh-tzu* that the Taoist philosophy developed.

**Lao-tzu.**—The fundamental doctrines of early Taoism are embodied in the *Lao-tzu*, also called the *Tao-te-ching*. Whether or not the book is an anthology of the 4th century B.C. (the point is disputed), its basic ideas and passages probably go back to Lao-tzu (q.v.), two centuries earlier. As the second title indicates, it is a classic on *Tao* and *te*, the "Way" and its "virtue." Previously the connotation of *Tao* had been social and moral; in the *Lao-tzu* it connotes for the first time the metaphysical. *Tao* "exists before heaven and earth." It is the "mother" and "ancestor" of all things. It is their "storehouse." It is at once their principle of being and their substance. "All things depend on it for life." It is One, everlasting, and unchangeable; it "operates everywhere and is free from danger." It is "invisible," "inaudible," "vague and elusive," but there is in it the "form" and the "essence." It is so absolute that it cannot be described; it "has no name." Furthermore, it is "nonbeing." The last idea, which appears to be nihilistic, simply means that *Tao* is prior to and above all things.

In its operation *Tao* is characterized by *wu-wei* (literally "no action"), which really means taking no unnatural action. It means spontaneity, noninterference, letting things take their own course. *Tao* "takes no action" but "supports all things in their natural state," and in this way "all things will transform spontaneously." As things arise, "*Tao* does not turn away from them." "It benefits all things but does not compete with them." "*Tao* invariably takes no action, and yet there is nothing left undone."

When man follows this natural way, he will abide with the one, the eternal, and the whole and will achieve a life of peace, harmony, and enlightenment. In dealing with things, he will "produce them but not take possession of them." In government he will adopt the policy of *laissez faire*, for "the best rulers are those whose existence is merely known by the people. . . . They complete their work. Nevertheless their people say that they simply follow Nature." Thus the natural way stands in direct opposition to all artificial regulation, organization, and ceremonies. This is the reason why the *Lao-tzu* vigorously attacks all formalities and artificialities. For the same reason it condemns war, taxation, punishment, superficial knowledge, and conventional morality.

The natural way is compared with the ways of water, the female, and the infant; that is, the ways of the weak. Along with weakness, the *Lao-tzu* also advocates humility, contentment, ignorance, submission, knowing where to stop, doing away with desires, accepting disgrace, and the like. This seemingly negative morality is deceptive. After all, "the greatest skill seems to be clumsy, and the greatest eloquence seems to stutter." "There is nothing softer and weaker than water, and yet there is nothing better for attacking hard and strong things."

While the weak seems to be glorified, the strongest stress really is on simplicity. A simple life is one of plainness in which profit is discarded, cleverness abandoned, selfishness eliminated, and desires reduced. It is the life of "perfection which seems to be incomplete" and of "fullness which seems to be empty." It is the life which is "as bright as light but does not dazzle." In short, it is the life of "superior virtue." This life requires all the important moral qualities taught in almost all ethical systems. To Lao-tzu, deep love, frugality, and not daring to be ahead of the world are "three treasures," and because of them one becomes courageous, generous, and a leader of the world. He urges us to love the earth in our dwelling, love what is profound in our hearts, love humanity in our associations, love faithfulness in our words, love order in government, love competence in handling affairs, and love timeliness in our activities. He wants us to maintain steadfast quietude and to be tranquil, enlightened, all-embracing, impartial, one with Nature, and in accord with *Tao*. He teaches us to "benefit all things," to "treat those who are good with goodness" and "also to treat those who are not good with goodness,"

and to "repay hatred with virtue." He admonishes us not to have ulterior motives, to show or justify ourselves, or to boast, to be proud, to hoard things, or to be extravagant. He advises us to know the subtle and the eternal, but when we do not know anything, to know that we do not know. Virtually all the ingredients of a virtuous life, including the Golden Rule, are included.

In short, the life of superior virtue is one of goodness, enlightenment, peace, and long life.

**Yang Chu.**—The note of life preservation is particularly strong in Yang Chu (q.v.), who may or may not have been an early Taoist. According to surviving isolated passages of his writings, he would not enter an endangered city, would not join an army, and would not care to exchange a single hair for the profits of the entire world. His main purpose in life was to "preserve life and keep the essence of his being intact." Mencius (q.v.) attacked him as an "egoist who denied the special relationship with the ruler." Whether Yang's doctrine actually degenerated to an irresponsible egoism or whether Mencius distorted it is a moot point. Yang Chu's teachings are certainly twisted in the "Yang Chu" chapter of the *Lieh-tzu* (see *Later Developments*, below) where his doctrine of self-preservation is coupled with pessimism on the one hand and hedonism on the other.

**Chuang-tzu.**—All the basic ideas in Lao-tzu are elaborated in the teachings of Chuang-tzu (q.v.). But his system is more than an elaboration; in it Taoism was extended to new dimensions and to a higher degree. To him, existence is not only spontaneity but the state of constant flux and incessant transformation. In Lao-tzu, the major notes are constancy and eternity; change is a minor one. In Chuang-tzu, change is the main theme. He conceives of the universe as a great current in which one state succeeds another in endless procession. No state can be retained, and time cannot be arrested. Life goes on "like a galloping horse." In these constant changes, things transform themselves by themselves, for this is the nature of things. There is no directing agency in this dynamic drama: "if there is a true director, there is no evidence of him."

In this process of rapid change, everything must follow its own nature. It is the nature of the eagle to fly high in the clouds, the nature of the dove to hop from tree to tree. A cypress will last for a thousand years, a mushroom for only a day. Each should live according to its nature. Similarly a man should be contented with his fate and "should not attempt to replace the way of heaven with the way of man." This is the true meaning of *wu-wei*. Though there is a much stronger element of fatalism in Chuang-tzu than in Lao-tzu, following Nature to him does not mean blind submission but rather a realistic recognition of one's own limits.

In the universe, then, there are these individual and continuous transformations, each in its own natural way. Such a universal process of rising and falling, of life and death, inevitably results in a world of differences and inequality, but all these are superficial, relative, often products of subjective points of view. Life and death cause each other, and neither right nor wrong is absolute. This and that, and possibility and impossibility, Chuang-tzu says, mutually produce each other. In reality, "all things are one," for *Tao* embraces all of them and combines them into a unity. A man of small knowledge will cut things up, discriminate, and make distinctions; a man of great knowledge will be comprehensive, impartial, and see *Tao* in all its unity. The ideal man will be a "companion with Nature" and a "friend of both life and death." He makes oneness his eternal abode. He abandons selfishness of all descriptions, be it fame, wealth, bias, or subjectivity. He knows his nature, nourishes it, and adapts it to the universal process of transformation. In this way he can "roam the universe" and be "emancipated." Having attained enlightenment through "the light of Nature," he moves in the realm of "great knowledge" and "profound virtue." He is then spiritually free. As the *Chuang-tzu* itself says of him,

Alone he associates with heaven and earth and spirit, without abandoning or despising things of the world. He does not quarrel over right or wrong and mingles with conventional society. . . . Above, he roams with the Creator, and below he makes friends with those who transcend

## AN ICONOGRAPHICAL REPRESENTATION OF SOME CONCEPTS OF TAO

BY COURTESY OF NELSON GALLERY OF ART, KANSAS CITY, MO.

"Fishing in a Mountain Stream," painting by Hsü Tao-ning, 11th century, ink on silk. Its sweeping view, comprising a number of well-harmonized elements, suggests the Taoist concept of the unity of the universe; the fewness and the smallness of the human figures convey the Taoist idea of man's relative role in the universal order.

life and death and beginning and end. In regard to the essential, he is broad and comprehensive, profound and unrestrained. In regard to the fundamental, he may be said to have harmonized all things and penetrated the highest level. However, in his response to change and his understanding of things, his principle is inexhaustible, traceless, dark and obscure, and unfathomable.

In Chuang-tzu, Taoism reached the transcendental and mystical level, but its dynamism and realism became at the same time much stronger. Generally speaking, Chuang-tzu's universe is much more complex than that of Lao-tzu. It involves not only the states of being and nonbeing but also that of neither being nor nonbeing. Lao-tzu's way is directed chiefly to handling human affairs; that of Chuang-tzu aims chiefly at dealing with the universe. Lao-tzu's goal is social and political reform; that of Chuang-tzu is to "travel beyond the mundane world." Every passage of the *Lao-tzu* can be understood in terms of ordinary human experience, but what Chuang-tzu wants is pure experience—that is, identification with the universe. He speaks of "fasting of the mind," in which "the mind is empty to receive all things," and of "sitting down and forgetting everything," in which "the body is abandoned, the intelligence is discarded, one is separated from the body and free from knowledge, and one becomes identical with a great penetration." At the same time, in his emphasis on being true to one's own nature, his philosophy is much more individualistic than that of Lao-tzu. While the notes of mysticism, quietism, and fatalism are stronger, the ultimate goal is preservation of one's original nature and through it absolute spiritual freedom.

From the time of Chuang-tzu till the 2nd century B.C., the Taoist School remained influential. It was the chief rival of both Confucianism and Moism. Followers of Lao-tzu, Yang Chu, and Chuang-tzu probably traveled in slightly different directions, but the main tenets remained prominent and clear. Later they were synthesized in the *Huai-nan-tzu*.

**The *Huai-nan-tzu*.**—The *Huai-nan-tzu* is an anthology of treatises by Liu An (d. 122 B.C.), prince of Huai-nan, and scholars who gathered around him as his retainers. It represents a combination of Taoist teachings, and as such its originality is negligible. In it, however, the concept of Tao becomes more concrete. Using water as its analogy, the writer describes Tao as a concrete reality, all pervasive, the cause of all things, perfectly weak, taking no unnatural action, and yet bringing all things into completion. Furthermore, cosmogony becomes more elaborate and more definite. "There was a time before the time which was before the beginning," and "there was a time before the time which was before nonbeing." "Before heaven and earth took shape, there was only undifferentiated formlessness," which was called "the great beginning." In cosmological evolution, Tao originated from vacuity, and vacuity produced the universe, which in turn produced the material forces. The material forces of heaven and earth combined to form *yin* and *yang*, which in their turn give rise to the myriad things. In its broad outline this cosmogony has remained orthodox doctrine not only among Taoist philosophers but also among the later Confucianists.

In its attempt at synthesis, the *Huai-nan-tzu* combines certain non-Taoist elements, such as the Confucian emphasis on learning as a method of self-cultivation and the Legalist emphasis on law in government. In its discussion of the spirit, it even introduces such ideas as immortality on earth and the techniques of breathing, etc., to achieve it, thus paving the way for the later confusion of Taoist philosophy with Taoist popular religion. In spite of this fact, it maintained Taoism at a time when Confucianism had assumed the dominant role in government and thought. In addition, by approaching metaphysics and cosmology in an essentially rational spirit, it prepared for the emergence of rationalistic Neo-Taoism.

**Later Developments.**—In the 3rd and 4th centuries A.D., Taoism developed in three directions. The first was Neo-Taoism, the most important philosophical development in the history of Taoism, which finds expression in the commentaries on the *Lao-tzu* and the *Book of Changes* by Wang Pi (q.v.) and the commentary on the *Chuang-tzu* by Kuo Hsiang (d. 312), who probably appropriated ideas from Hsiang Hsiu (fl. 250). In them, nonbeing is no longer essentially in contrast to being but is the ultimate of all, or pure being (*pen-wu*), the One and the undifferentiated. According to Wang Pi, original nonbeing is beyond distinctions and descriptions. It is the pure being, original substance (*pen-t'i*), and the One in which substance and function are identified. It is always correct because it is in accord with principle. For Lao-tzu's destiny, Wang, anticipating Neo-Confucianism, substituted principle.

In the work of Kuo Hsiang, who carried Chuang-tzu's thought further, Nature (*tsu-jan*), not Tao, is the major concept. Things exist and transform themselves spontaneously, each according to its own principle. Compared with Wang Pi, Kuo Hsiang emphasizes being rather than nonbeing and the many rather than the one. To Wang Pi, principle transcends things; to Kuo Hsiang, it is immanent in them. To neither of them, however, is the sage one who withdraws into a hermit's life; he lives a life of social and political accomplishment, through taking no unnatural action. Significantly, the greatest sage to them was not Lao-tzu but Confucius.

The second movement was that of the "pure conversation," a way of life expressed in elegant, refined, and carefree conversation, devoid of the vulgarity of politics, earthly ambitions, and worldly values. It lasted from the middle of the 2nd century through the 6th, with Juan Chi (210–263), Hsi K'ang (223–262), and Hsiang Hsiu as outstanding representatives.

The third movement was fatalistic naturalism, represented by the *Lieh-tzu*, a product probably of the 3rd century. Its ideas are all original ingredients of Taoism, but the Taoist doctrine of taking no action has degenerated into complete abandonment of effort, spontaneity is confused with resignation, and having no desire is replaced by hedonism—all negative developments. On the positive side, Tao as the self-caused ultimate reality is much more strongly affirmed, and vacuity in the sense of eliminating desires and renouncing egoism is emphasized. In both of these the *Lieh-tzu* goes beyond Lao-tzu. In being indifferent to life and death and in ignoring the distinction of right and wrong, it pushes skepticism to the extreme; and in considering unceasing transformation as going in cycles according to fate, so that life and death, by their very nature, immediately succeed each other, it gives the doctrine of transformation a peculiar form. In these the *Lieh-tzu* goes beyond Chuang-tzu. In teaching that one should do away with the distinction between oneself and others, avoid a subjective state of mind, be vacuous, pure, and tranquil, and be in accord with Nature, it is essentially Taoistic and may well reflect, or even transmit, the teachings of Lieh-tzu, or Lieh Yü-k'ao (c. 450–375 B.C.), whose work had disappeared centuries before.

**Influence.**—As a philosophy Taoism declined after the 4th century, by which time Taoism and Buddhism had begun mutually to influence each other. In the 3rd and 4th centuries, Buddhist thinkers practised "matching the concepts" of Buddhism and Taoism, as a result of which Buddhists interpreted their philosophy in Taoist terminology while Taoism assimilated Buddhist ideas. Although Taoism eventually became a handmaid of Buddhism, it exercised far greater influence on Buddhist philosophy than vice versa. The major Taoist concepts of being and nonbeing were carried over to Buddhism. Some early Buddhist schools even called themselves "School of Original Nonbeing," "School of Nonbeing of Mind," etc. Like the Neo-Taoists, the Buddhists regarded ultimate reality as transcending all being, names, and forms, and as empty and quiet in Nature.

The greatest influence on Buddhism may be seen in the Chinese development of the Buddhist Meditation School (Ch'an or Zen; see ZEN). The Taoist tenets that Tao is everywhere, is indescribable, and can be discovered through enlightenment had a direct bearing on the development of Zen doctrines that the Buddha

mind is everywhere, is indescribable by words and inconceivable in thought, and can be realized through enlightenment. The standard ways of Zen enlightenment are "absence of thought," "forgetting one's feelings," and "letting the mind take its own course," literal borrowings from Taoism, especially from Chuang-tzu. Many early Buddhist thinkers were experts in Taoist philosophy, and throughout history many Zen masters have been personal friends of Taoists.

Just as Taoism contributed to the development of Zen in the 7th and 8th centuries, so it contributed to the development of Neo-Confucianism in the 11th (see CHINESE PHILOSOPHY), but because of their "way of quietness and nonactivity," the Neo-Confucianists severely attacked the Taoists, and, as a result, Taoism ceased to be a vital philosophical system in the last millennium. As a way of life, however, it has never lost its hold on Chinese culture and society. Its spirit of harmony, simplicity, and peace has been eloquently expressed in Chinese landscape painting, landscape gardening, poetry, tea drinking, etc., and its spirit of naturalism, individualism, and freedom has strongly molded Chinese life. See also CHINESE PHILOSOPHY.

## RELIGIOUS TAOISM

**The Way of the Yellow Emperor.**—While the philosophy of Taoism was unfolding, a religious current, in progress from time immemorial, was developed by priest-magicians who offered divination and magic as means to inward power, restored youth, superhuman ability, and, most importantly, immortality on earth. Somehow this movement came to be known in the 1st century B.C. as the Way of the Yellow Emperor (Huang-ti) and Lao-tzu, and enjoyed an extensive following. In A.D. 143 Chang Ling, also called Chang Tao Ling, a popular religious leader famous for healing the sick, formally organized the movement and required his many followers to donate five piculs (bushels) of rice (hence the name the Way of Five Piculs of Rice). His followers called him Heavenly Teacher, a title his direct descendants retained until the 1940s.

From the very beginning the Yellow Emperor-Lao-tzu movement was a conglomeration of sorcery, the arts of priest-magicians, and the philosophy of the Yin-Yang School, according to which all things are products of the cosmic negative and positive forces. Gradually it assimilated certain elements of Taoist philosophy. Wei Po-yang (fl. 147–167) combined all these in a coherent system and thus laid the philosophical foundation of the Taoist religion. In his *Ts'an-t'ung-ch'i* ("The Three Ways Unified and Harmonized"), he attempted to synthesize all these ideas for the sake of prolonging life through the practice of alchemy, whereby, it was believed, the two cosmic forces could be harmonized and the vital force (*ch'i*) of the universe concentrated in the human body. His book became the basis of the *Lung-hu* ("Dragon and Tiger") *Scripture* of unknown date, the *Huang-t'ing* ("Internal and External") *Scripture* (3rd century), and the *Yin-fu* ("Secret Accord") *Scripture* (8th century). Later, Ko Hung (253–333?), also called Pao-p'u-tzu, synthesized Taoist philosophy and Confucian ethics. His chief concern, however, was alchemy to prolong life, and he strongly defended the belief in immortals (*hsien*).

These two philosophers provided religious Taoism with a firm theoretical foundation and an elaborate system of practice. It was K'ou Ch'ien-chih (d. 432) who made it an organized religion, by regulating the ceremonies, fixing the names of deities, and formulating theology. His influence led to its being made a state cult in A.D. 440. State patronage reached its height in the T'ang dynasty (618–906), since when religious Taoism has existed primarily as a religion of the illiterate masses.

**Features.**—As a religion, Taoism is distinguished by several prominent features, outlined below.

**Multiplicity of Gods.**—Taoism has a god for almost everything—stars, animate and inanimate things, the whole and parts of the body, ancestors, famous historical beings, ideals, etc. Among these are the Jade Emperor, the Three Pure Ones (Heavenly Honoured Ones Without Form, With Form, and Brahma Form), the Dipper Star, the Great Unit, Gods of Literature, Wealth, Medicine, Kitchen, and Goddess of Mercy (from Buddhism). It worships

numerous immortals, has 10 "Heavenly Grottoes," 36 subsidiary "Heavenly Grottoes," and 72 "Blessed Places," where immortals rule and await people to seek the "way." Besides, there are imitations of many Buddhist heavens and hells.

**Search for Blessings and Longevity.**—Popular Taoism is strongly characterized by piety and devotion, but its chief objectives are earthly blessings—happiness, health, wealth, the begetting of children, and, most of all, longevity. By the 7th century an elaborate system of practices was developed to achieve these blessings and to realize the Three Original Principles of Taoism, namely, Essence, Vital Force, and Spirit. These practices included breath control, baths, diet, mental concentration, sex hygiene, physical exercises, medicine, the use of charms, attempts at disappearance and change of bodily form, and alchemy, especially the effort to transmute mercury into gold. In their pseudoscientific alchemical experiments over the centuries, the Taoists made a number of scientific discoveries and perhaps contributed indirectly to the development of science in Europe.

**Superstitions.**—The Taoist religion is a rich reservoir of superstitions, including geomancy, fortune-telling, divination, and the use of charms. With modern reforms, these are fast disappearing but not entirely eliminated.

**Sects.**—Taoism is a wholesale imitation of Buddhism, notably in its clergy, temples, images, ceremonies, and canon. In organization it is generally classified under two schools, the Northern and the Southern. The Southern School, called the True Unity sect, prevailing south of the Yangtze, is traced to the so-called founder Chang Ling but more likely grew up in the 10th century. It emphasizes man's nature—that is, man's spirit or true self—and relies on charms and magic to preserve it. It depends on "self-power" and is idealistic and informal. Its priests are married, live at home, and regard as their head the Heavenly Teacher, who used to reside in the Dragon and Tiger Mountain in central China. He had no influence on the masses and should in no way be called a pope, as he sometimes has been in the West.

The Northern School, called the Complete Unity sect, probably founded in the 13th century, is centred at the White Cloud Temple in Peking. It emphasizes man's life—that is, man's vital force—and relies on medicine and diet to prolong it. It depends on "other-power" and is materialistic and formal. Its priests renounce the home, adopt vegetarianism, and live in temples.

**New Societies.**—The two schools have been declining since the last half of the 19th century. In their place new societies have grown up, such as the Tao Yuan (Society of the Way), founded about 1920. These are led by laymen, worship deities of all religions, shun superstition, reject the search for earthly immortality but promote charity and moral culture, and, like traditional Taoist sects, sometimes participate in political revolts.

**Ethical Teachings.**—To most followers, who also follow Confucianism and Buddhism, the Taoist religion is essentially a sanction of ethics. In the two most popular tracts, *The Treatise on Influence and Response* and *The Silent Way of Recompense*, which have been influential for centuries, Confucian moral values (filial piety, loyalty, love, righteousness, and good faith), Buddhist virtues (compassion, kindness to all creatures, and remonstrance against all evil deeds), and Taoism's own ethics of patience, simplicity, contentment, and harmony are strongly advocated.

**Modern Status.**—As a religion of the masses, Taoism has been rapidly fading away, especially since the Communist government came to power in China. Without leadership, financial resources, or recruitment for priests, its future as an organized religion is dim, although private practice, including local temples and shrines in homes, will surely continue. Its superstitions, animism, and idolatry, however, have largely been replaced by social and economic reform activities. Although there is a National Taoist Association in Mainland China, practically all Taoist priests have returned to secular and productive life, and Taoist temples are being used for other purposes. But many elements of the Taoist religion—its fairy tales, magic, aesthetic imagination—are still rich in Chinese folk life, especially in festivals, while the virtuous life and spiritual serenity taught in its religious tracts will continue to influence the Chinese character for a long time to come.

**TAORMINA**, a town and tourist resort on the east coast of Sicily in the province of Messina, about 35 mi. (56 km.) from the towns of Messina and Catania, is on a hill that rises almost perpendicularly from the sea, near the foot of Mt. Etna. Pop. (1961) 8,903. The famous Greek theatre, rebuilt in Roman times, stands on the spur of Mt. Tauro, which affords a splendid view of Mt. Etna from summit to base on the southwest, and the mountains of Calabria across the sea to the north. There are remains of the Roman Odeon theatre, discovered during excavations in 1892, and of the so-called Naumachia (a reservoir), almost in the centre of the town. The Corvaia Palace, the Santo Stefano Palace (a splendid construction with fine paired windows), the Badia Vecchia, and the Ciampoli Palace belong to the medieval period. Taormina is connected by road and rail with Messina and Catania.

The town was the ancient Tauromenium, which took its name from Mt. Tauro, and was originally a settlement of the Siculi, resettled by Dionysius of Syracuse about 392 B.C. After receiving a further colony of refugees from Naxos in 358, it flourished under the mild rule of Andromachus, father of the historian Timaeus. Tauromenium was part of the kingdom of Hieron II from 263, and in about 210 it passed to the Romans as an allied city. Augustus made it a Roman colony, but it declined under Roman, and later Byzantine, rule. In A.D. 902 the city was taken by the Arabs, who destroyed it and massacred the population. Rebuilt by the Christians of Val Demone as New Taormina, it was again taken in 962 by the Arabs under the amir Ahmad, who renamed it Mu'izziyah. In 1078 it was taken by the Normans, under whom it had some prosperity, but it has remained a modest township. (A. R. T.)

**T'AO YUAN-MING:** see T'AO CH'EN.

**TAPACOLO** (TAPACULO), the name given to a group of small to medium-sized birds comprising the passerine family Rhinocryptidae, peculiar to Central and South America. The 25 known species occur chiefly in the Andes, and are most numerous in Chile. A single species (*Scytalopus argentifrons*) occurs as far north as Costa Rica. The several types agree in having large, strong feet, rounded wings and rather short tails which are carried in an upright position. The bill may be either thin and awllike or decidedly thick. Certain modifications of the external nostrils are characteristic of the family. In coloration the plumage is mainly brownish or blackish and, in one form, spotted. The typical tapacolo (*Rhinocrypta lanceolata*), a native of Argentina, is crested and resembles a miniature domestic fowl. The widely distributed, wrenlike genus *Scytalopus* includes more than half of the known forms. All are notably furtive, have weak powers of flight and frequent bushes or undergrowth. Their varied calls are sometimes musical, but consist chiefly of harsh scolding notes.

Tapacolos feed on insects, larvae and related matter. Their nesting habits vary, some forms (*Scytalopus*) making nests on the ground and others in bushes. One species (*Teledromus fuscus*) digs a tunnel. Two white, unmarked eggs comprise a clutch. (E. R. BE.)

**TAP DANCE.** Tap dancing is a style of dance, which can be incorporated into any form of dance movement, in which more foot-to-floor contacts than normal are produced, in precise, rhythmic patterns. The taps are made audible by attaching small metal plates to the toe and heel of the dancing shoe.

All ethnic groups have retained some form of emphatic foot-to-floor contacts as part of their dance culture. The main sources of tap dancing, however, are the clog dancing of northern England (see CLOG DANCE), the reels and flings of Ireland and Scotland, and the rhythmic foot stamping of the African Negro; these basic elements came together in the United States. The 19th-century performers in minstrel shows and showboats stylized and fused them into a form of dance and satire which rapidly became popu-

lar. Among the most noted of these performers were Ralph Keeler and Daniel Emmett and the dance team of Lynch and Diamond.

Near the end of the 19th century tap dancing acquired two specific techniques called "buck-and-wing," and "soft-shoe." The buck-and-wing was very active and fast, and was danced in wooden-soled shoes that made loud sounds. Soft-shoe was very relaxed and smooth and was danced in soft shoes. At the turn of the century, George Primrose was the most famous of the soft-shoe dancers, while Doyle and Dixon were exponents of the buck-and-wing.

Between 1910 and 1925 these two varieties of tap dancing merged and the modern metal tap made its appearance. The technique remained very much the same, consisting principally of: striking the ball of the foot on the floor with a brushing motion forward, sideward, or backward; stepping on the ball of the foot; dropping or scuffing the heel on the floor; scraping the foot over the floor; touching the toe of the foot to the floor; and making contact with any part of the shoe which would produce a sound. Handclaps and slapping of the body were also occasionally used. These steps were combined with a great variety of leg movements. Some of the tap dancers who began dancing during this period were Pat Rooney, George M. Cohan, the Four Fords, Johnny Boyle, Tom Patricola, and the great Bill Robinson, known as "Bojangles." In the 1930s tap was very popular for chorus dancing and in vaudeville.

Since 1940 tap dancing has added to its basic technique many of the movements of ballet and modern dance. The footwork has also developed so that an expert tap dancer can make about 64 taps in five seconds and, standing on one leg, can make 5 tap sounds with a single movement of the supporting leg.

As tap dancing became more visually interesting, it was widely used in motion pictures, outstanding performers including Fred Astaire, Gene Kelly, Ray Bolger, Ginger Rogers, Eleanor Powell. A *Concerto for Tap Dancer* was composed by Morton Gould, to be performed with orchestra. Paul Draper introduced tap dancing in the concert field with classical and jazz music. (P. Dr.)

**TAPE RECORDING, MAGNETIC.** The process of magnetic tape recording offers one of the most accurate and convenient methods of storing, and later reproducing, any type of information that can be converted into electrical signals. Sounds (e.g., voice and music), electrical data from business machines and metering devices, video signals and the electrical impulses for the automatic control of machinery are examples of the material commonly stored on magnetic tape. Besides the accuracy and convenience of magnetic recording, the ability to erase the storage medium and reuse it many times gives a great economic advantage over other recording methods in many applications.

**History.**—The idea of storing electrical information by means of magnetized particles was expressed as early as 1888 by Oberlin Smith in an article in *The Electrical World*. However, Valdemar Poulsen, a Danish inventor, was the first to reduce the idea to practice with a recorder which stored the electrical signal on a wire of magnetic steel. He first applied for a Danish patent on this device on Dec. 1, 1898. A working model of the device created great interest at the Paris exposition in 1900, and many of the later applications of magnetic recording were envisioned at that time. Even with this enthusiasm, however, Poulsen could not find financial backers in Europe. In 1903, Poulsen and some American associates formed the American Telegraphone company for the manufacture and sale of an improved version of the device. The telegraphone would record continuously for 30 minutes on a length of piano-wire steel that moved at a speed of 84 in. per second. However, the device did not find wide application.

Following the failure of Poulsen's company, the general public heard little of magnetic recording for several years, but interest continued in many laboratories. W. L. Carlson and G. W. Carpenter of the U.S. Naval Research laboratory applied for a patent on alternating-current bias for magnetic recording in 1921, and in 1927 J. A. O'Neill received the first U.S. patent for a magnetic tape made by drying a liquid containing magnetic particles on the surface of a strip of paper. A German patent by Fritz Pfelemer

of Dresden was issued in 1928 for a similar process. Until this time, the recording medium had been a wire or tape, entirely of or plated with magnetic metals.

During the 1920s Kurt Stille of Germany acquired a number of patents in this field through which he licensed others. One such licensee was Louis Blattner of England, who built a magnetic recording machine to record and synchronize sound with motion pictures. The "Blattnerphone" was used by the British Broadcasting corporation, and later it was bought by the Marconi company. Work on this method of recording progressed in Germany, England and the U.S. during the 1930s. In particular, the Magnetophon company of Germany succeeded in producing a magnetic film-coated tape, based on Pfelemer's patent, that constituted a low-cost recording medium. During World War II the Magnetophon, using the coated tape, served the Nazi propaganda organizations well, and following the war its principles were copied and improved upon in many countries, with Germany, England and the U.S. the leaders in this work.

**Recording Media.**—Magnetic materials in almost every possible form are used in one magnetic recording application or another. Drums of nonmagnetic material have their surfaces coated with a magnetic material to record short bursts of information, such as those used in electronic computers and some types of data recording. Cylindrical surfaces of rubber or plastic, impregnated with magnetic particles, are used to record short messages in telephone answering and recording machines. Disks, coated or impregnated with magnetic material and recorded in parallel or spiral tracks, are used in such applications as office dictating machines and electronic computers.

Wire, the first magnetic recording medium, is still used for certain applications, such as portable recorders. Despite improvements in tape, drums, etc., more information can be stored in a given space on wire than on any other medium. However, the fidelity of reproduction, the signal-to-noise ratio, and cross talk (resulting from adjacent recorded layers being wound together on the same spool) are generally poorer than those of tape.

A variety of magnetic tapes have been developed. Some of the early machines used a solid metal tape of magnetic material. A magnetic stainless steel, Vicalloy, consisting of 52% cobalt, 11% vanadium and 37% iron, is particularly useful for both wire and tape. However, a paper or plastic tape coated with a magnetic powder proved to be the most useful form of magnetic recording material and far outstripped the others in variety of application as well as volume produced.

The magnetic material most often used in coating tape is the red form of iron oxide,  $\text{Fe}_2\text{O}_3$ . The way in which this powder is prepared, the impurities deliberately introduced or accidentally present, and the physical size and shape of the particles have much to do with the characteristics obtained. Red iron oxide particles, needle-shaped and roughly one micron ( $1.000.000$  m.) in length, are widely used. The black oxide,  $\text{Fe}_3\text{O}_4$ , has also been used as a magnetic coating material; it produces a higher signal strength, but is more difficult to erase.

The magnetic powder is thoroughly mixed with a binder, the nature of the latter depending partly on the base material to which it will be applied. The polymeric vinyl chlorides, vinyl acetate, cellulose acetate and ethyl cellulose are commonly used. The solvent employed must not attack the base material or cause adjacent layers of tape to stick to each other when the tape is tightly wound and stored at relatively high temperatures. The object is to obtain a very thin but dense layer of iron oxide on the tape in a very uniform distribution. It must adhere tightly to the base tape, but not to an adjacent layer; it must be flexible, and preferably its characteristics should not change appreciably over many thousands of usages or many years of storage.

The base material may be paper or any one of several plastics. Paper is generally lower in cost and some papers are more stable than plastics in applications where relative humidity and temperature vary widely. However, paper tears easily under tension, and since any irregularity in the thickness of the magnetic layer results in unwanted variations and noise in the recording, even the smoothest paper has a serious disadvantage in performance.

compared with plastic, which can be prepared with very smooth surfaces.

Cellulose acetate film can be manufactured at moderate cost with a smooth surface, and it has reasonably good tensile strength, tear resistance and dimensional stability. It is widely used for magnetic tape in thicknesses of about 0.0015 in. Mylar or Terylene (a polyester made from polyethylene terephthalate) is more expensive than cellulose acetate, but has superior characteristics. It is stronger, and more stable under high humidity and temperature conditions. It is also more stable with respect to time, making it possible to store recorded material for many years. It has sufficient strength and stability to be used in films as thin as 0.0005 in., thus greatly reducing the storage space required for a given length of tape. However, a smooth surface is somewhat more difficult to obtain on Mylar than on cellulose acetate.

A typical method of manufacturing tape begins with combining the iron oxide and the binder. The mixture is milled in a large rotating cylinder loaded with steel balls, a process that may require from one to several days. The resulting mixture is an extremely uniform, thick fluid resembling printer's ink. This is filtered to remove any lumps of more than about one micron in diameter.

The paper or plastic film is usually processed in webs up to 20 in. wide. The coating process is done in very clean rooms where only filtered air can enter. The web passes from its roll through a cleaning stage in which both surfaces are cleaned of every trace of dust, lint and other foreign matter; this is accomplished with vacuum suction action, assisted by static removal equipment. The web is then coated with a thin layer of solvent to make the surface receptive to the coating material. When this has had sufficient time to act on the surface, the magnetic coating is applied. This may be done in a fashion similar to engraved-roll printing, in which the amount of material to be applied is metered by the depth of the pattern engraved in the surface of a printing plate. The magnetic mix is applied to the engraved roll and the surface rubbed or scraped to remove the excess. The amount remaining in the engraved pattern is then transferred to the tape web by a rolling action, and the web continues through a drying chamber. When it is dry, the surface may receive a polishing, after which the tape web is ready to be slit and reeled.

The coating remaining on the web is 0.0001 to 0.0004 in. thick when dry, and tolerances of  $\pm 0.000012$  in. may be held on the nominal thickness to assure proper performance. For tapes that are used for computers, automatic inspection devices detect any voids in the coating, since these could cause an omission in the stored information, resulting in a serious error.

The tape is slit and wound on reels varying from 3 to 14 in. or more in diameter, depending on the intended application. A 7-in. (outside diameter) reel is common in sound recording work and holds 1,200 to 1,800 ft. depending on the tape thickness.

A 10½-in. reel (2,400 to 3,600 ft.) is widely used by the broadcast industry, and larger reels are frequently used in technical data recording and business-machine operations. Nominal tape widths most commonly used are ¼, ½ and 1 in., with the ½-in. size having the widest variety of applications.

**The Recording Process.**—The electrical signal to be recorded is usually applied to the tape by means of a "head" consisting of a coil wound around a core of magnetic iron which has a gap at the point where the tape moves across its surface. The current in the coil produces a magnetomotive force across the gap, magnetizing the particles in the tape. The strength and direction of final magnetization of a particular point on the tape will be determined by the strength and direction of the magnetic field at the moment that point crosses the gap. Thus the tape receives a magnetic record containing direction (north or south pole), amplitude, and linear dimension (along the tape) corresponding to the direction (plus or minus), amplitude and time of the original electrical signal. The exactness of this record depends on a variety of conditions, one of the most important being the original magnetic condition of the tape. There are two conditions which give predictable results. Either the tape should be completely demagnetized before recording, or it should be completely mag-

netized in one direction or the other. In early wire and tape recording, the latter condition was used. The tape was carried past a permanent magnet so arranged that it brought the magnetic particles to saturation, leaving the tape fully and uniformly magnetized in one direction. The recording head then had a direct-current component added to the signal; this direct-current bias was of the proper direction and amplitude to bring the tape just back to a neutral state. The signal, adding and subtracting from this bias, left the tape magnetized by an amount proportional to its own strength. This is called D.C.-biased recording, and gives comparatively low distortion and good amplitude. However, it has a higher inherent noise level and more distortion than A.C.-biased recording.

In A.C.-biased recording the tape is first completely demagnetized and comes to the recording head in a neutral state. There an alternating current is added to the signal current; it is much higher in amplitude than the signal current, and several times greater than the frequency of the highest-frequency signal to be recorded. In crossing the gap of the recording head the magnetic particles on the tape are subjected to many cycles of the bias current, and leave the head with a magnetization which is proportional to the signal. Very low distortion and high signal-to-noise ratios can be obtained with A.C.-biased recording. For sound and general signal recording, this type of tape recording gives performance superior to that of any other recording method.

For pulse recording, in electronic computers and other digital information devices, distortion is of no importance. It is simply desired to record and later detect the presence of a pulse. In most of these recorders the tape comes to the recording head in a neutral state.

In one system the head may normally carry a current that magnetizes the tape to saturation in one direction. A pulse then carries the current to the other extreme and back again, leaving a short area on the tape magnetized in the opposite direction. This is called two-level recording.

In the other commonly used system the head normally carries no current, and pulses may carry the magnetization of the tape to saturation in either a plus or minus direction. This is called three-level recording.

Losses are encountered in recording through eddy current and resistive and capacitive losses in the windings and core of the head. Space between the head and tape causes very high losses, particularly at high frequencies (short wave lengths). The gap must be very straight and true, and the surfaces in contact with the tape must be very smooth in order to obtain the best possible transfer of the signal pattern onto the tape. Optical polishing methods are commonly used for finishing the surfaces of the gaps and faces of the head that will be in contact with the tape. The gaps used in recording heads vary in length (direction of tape motion) from 0.0002 in., when used also as a reproducing head, to 0.010 in. or more for specialized applications. The tolerances on the trueness of the faces and edges of the gap are usually held to a few millionths of an inch. The width of the cores, and the resulting recorded tracks on the tape, vary from approximately 0.025 in. for certain types of data recording to 0.250 in. for professional audio recording.

**Reproduction.**—In reproduction, it is usually desired to use the recorded tape to reconstruct the signal, obtaining the same polarity, amplitude and time relationship that originally existed in the recorded signal. To accomplish this, the tape is passed over the same head used in recording, or one similar to it. To reproduce the signal in the proper time relationship, the tape speed must be identical during recording and reproduction.

The magnetized portions of the tape passing over the gap in the reproducing head cause the magnetic flux in the core to change, generating a voltage in the coil. This voltage is proportional to the speed of the tape and the amplitude and frequency of recorded signal. Assuming that the tape speed is constant and that a constant-amplitude signal has been recorded, the reproduced signal will have an amplitude proportional to the frequency of the reproduced signal. This gives a response which rises at the rate of 6 decibels per octave. However, as the lengths of the waves

recorded on the tape become smaller, the gap in the reproducing head spans more and more of a wave length, and a loss in output is encountered which is known as "gap loss." At the frequency where the gap just spans one wave length of the recorded signal, the output is zero. In order to use the tape at as slow a speed as practical and still record high frequencies (short wave lengths of recorded signal), the reproducing head has a gap made as short as the technical progress of the art, and economics, will allow.

The amplifier that obtains its signal from the reproducing head must have a response curve which compensates for the special characteristic of that head, as well as for other losses in the heads and recording process. Some of these losses can be anticipated and compensated for in the recording amplifier. Thus it is necessary to have standards established before tapes can be freely exchanged from one recording machine to another reproducing machine. This has been done to some extent in the audio field, standards being established by industry committees.

In television and data recording and in machine control the frequency response problems are quite specialized and the tapes are usually recorded and reproduced on the same machine or a similar model. Few standards have been established since they are not seriously needed for tape interchanges. In business machine applications the problems are even more specialized. Here, it is not necessary to reproduce exactly what was recorded, but merely to detect and interpret each "bit" or pulse of recorded information. The reproduced signal generally does not resemble the recorded pulse, but does bear a definite relationship to it.

**Erasure.**—One of the features of magnetic recording which gives it an economic advantage over other recording methods is the ability to erase and reuse the recording medium thousands of times with little or no loss in the quality of recording. Erasure may be accomplished in either of two ways: (1) A reel of tape may be erased by subjecting the whole reel to a strong alternating magnetic field and slowly reducing the field to zero; this is called bulk erasing, and is similar to the method used by a jeweler when demagnetizing a watch, although the equipment must be of a different form to accommodate the large reels of tape. (2) The second method involves using a head, very similar to a recording head, to erase the tape just before it is recorded again; the tape passes over the gap in the head and is subjected to a powerful, high-frequency alternating field which diminishes as the tape passes away from the gap, leaving the tape in a demagnetized or neutral state. Professional sound-recording engineers frequently use both methods to make sure all the previous recording has been removed from a tape before it is used again.

**Tape Recording Machines.**—A wide variety of mechanisms has been devised to make use of tape recording in many different applications. Since only a small amount of power is required to move the light, flexible tape over the heads for recording or for playing back, it has been possible to make battery- and spring-driven portable mechanisms to record away from established power sources; the smaller ones are pocket-sized. The miniature machines, however, sacrifice some fidelity of reproduction to attain compactness. In particular, it is difficult to attain smooth motion and uniform speed, with the result that "flutter" and change of pitch can be noted in the playback of audio material. Larger portable units are available which give quite high fidelity and are often used for broadcast program recording in the field.

A large market developed in tape recorders for use in the home. These record and play tape at 1.87, 3.75 and 7.5 in. per second, usually on one-half of the width of the  $\frac{1}{4}$ -in. tape; this doubles the amount of tape available for recording or makes it possible to have two simultaneous channels for stereophonic recording. Prerecorded tapes are available, but the ease with which the amateur can produce acceptable recordings is a strong factor in the popularity of such recording devices. Some machines are designed to record four tracks on a  $\frac{1}{4}$ -in. tape, allowing even more intensive use of the tape with only a slight further sacrifice in the quality of reproduction.

Sound recorders for special applications are often quite complex. Those used for professional studio recording usually have three motors: one on the supply reel, one on the take-up reel and

a third to drive the tape. Extreme care is taken to provide smooth and uniform drive so that reproduction of musical notes will remain in exact pitch with no discernible flutter. Another special application is voice-monitoring service, such as the monitoring of radio channels at an airport. Here, a 2-in. tape is used and a rotating head scans across the tape while the tape moves slowly forward. This makes possible a very long recording time on a comparatively short tape, and a particular passage may be returned to with a minimum of rewinding time.

The same principle, with much elaboration and much higher scanning speeds (1,500 in. per second), is in use for recording television broadcasts. The tape recorders used in data recording are similar to those used in professional audio recording. However, they may utilize wider tapes, and 10, 20 or more tracks may be provided by special multicore heads. In addition, the machines must be capable of starting and stopping the tape in very short intervals of time, and of driving the tape in either direction. The very low inertia of a short piece of tape makes it possible to attain speeds of 15, 30 or 60 in. per second in thousandths of a second. Various fast-acting capstans and brake systems are in use to start and stop the tape, and a slack loop is usually maintained between the reels and the working area by means of servomechanisms. See also **PHONOGRAPH**; and references under "Tape Recording, Magnetic" in the Index.

**BIBLIOGRAPHY.**—Joel Tall, *Techniques of Magnetic Recording* (1958); S. J. Begun, *Magnetic Recording* (1949); H. G. M. Spratt, *Magnetic Tape Recording* (1958); N. M. Haynes, *Elements of Magnetic Tape Recording* (1957); W. Earl Stewart, *Magnetic Recording Techniques* (1958). (W. E. St.)

**TAPESTRY** is popularly assumed to be almost any heavy material, ordinarily wool, hand-woven, machine-woven, or even embroidered, used to cover furniture, walls, or floors; and this definition is justified in that it perpetuates the meaning of the Greek and Latin words from which the English word "tapestry" derives. Neither word defined the technique by which such articles were made.

This broad application of the term, which has resulted in much ambiguity in the interpretation of ancient documents, was to a large extent abandoned in the 18th and 19th centuries when the technical definition of a tapestry was narrowed to embrace only patterned or figured handwoven textiles, usually in the form of hangings, curtains, or upholstery, made either by the low-warp or high-warp method, and having a solid, weft-faced surface. Contemporary usage therefore brings the meaning of "tapestry" closer to the medieval "arras," which was still the current term in Shakespeare's time and beyond for this type of hanging.

Tapestry weaving differs from embroidery in that it is freely darned on a bare warp instead of being wrought upon an already woven material. The celebrated Bayeux Tapestry (*q.v.*) of the 11th century is therefore not a tapestry at all in the sense that the word has now acquired, since the design is embroidered upon the material and not woven into it. (See also **WEAVING**; **RUG** AND **CARPET**.)

## TECHNIQUE

**Characteristics of Tapestry Weaving.**—Tapestry differs from other forms of patterned weaving in that no wefts are carried the full width of the web, except by a very rare accident of design. Each unit of the pattern or the background is woven with a weft of the required colour, which is inserted back and forth only over the spot or section where that colour appears in the pattern. Typically, in plain-cloth technique, the weft passes over and under the warps alternately, and on the return shoot, under where before it was over, and vice versa. The wefts, which are pushed tightly together by various devices (sword tip, reed, batten or comb), so outnumber the warps as to conceal them completely; the latter appear only as more or less marked parallel ridges in the texture, according to their coarseness or fineness.

Where the margin of a colour area is straight and parallel to the warps, a slit is necessarily left, which may be treated in one of five different ways. First, it may simply be left open, as in the Chinese silk tapestries, which are called *k'ssu*, "cut silk," for that reason. Second, it may be left open on the loom, but sewed

THE UNICORN IN CAPTIVITY

One of a series of English tapestries showing the legend of the unicorn. Fourth of a series. It was woven in 1615, has been acquired by the British Museum, and is now in the collection of the British Museum. It was woven in the workshop of the tapestry weavers of the wedding of Anne of Brittany to Louis XII of France in 1499. In the middle, the unicorn is a gift from the Harbinger, 1937.

#### FRANCO-FLEMISH TAPESTRY

"Courtiers with Roses," the second of a set of three tapestries made towards the middle of the 15th century, perhaps at the order of Charles VII. It is woven of wool in a coarse texture of about 12 warps to the inch. The tapestry, which recalls the paintings of Jean Fouquet, has great decorative qualities. Since its exhibition at the Louvre in 1904 it has been recognized as one of the most important tapestries of its period. It was purchased in 1909 by the Metropolitan Museum of Art, New York

A 20TH-CENTURY TAPESTRY

"Femme, Fleur, Étoile" (Woman, Flower, Star) by Joan Miró (1893– ). Spanish. The tapestry, in the Seagram building, New York city, is a reproduction of a painting. The tapestry work was supervised by Marie Cuttoli, Paris. From the collection of Joseph E. Seagram & Sons

"The Parade of the Buso" by István Ban, 1957. In the town hall of Mohács, Hungary. 10 ft. 10 in. × 15 ft. 9 3/4 in. (3 m. 30 cm. × 4 m. 82 cm.)

"The Five Wise and the Five Foolish Virgins," made in Romerike, Norway, in the mid-17th century. 77 1/2 × 61 in. (197 × 155 cm.)

"The Great Menace" from the series "The Song of the World" by Jean Lurgat, 1957. 14 ft. 5 1/4 in. × 29 ft. 6 1/4 in. (4 m. 40 cm. × 9 m.). "The Great Menace" depicts the bark of creation with man at the helm

up afterward, as in European tapestries from the 14th to the 17th centuries, and also in some later types. Third, the weaver may dovetail his wefts, passing from one side, and from the other, in turn over a common warp. This may be either "comb" dovetailing—single wefts alternating—or "saw-tooth" dovetailing—clusters now from one side, now the other. Dovetailing has the double disadvantage of making the fabric heavier at that point and of blurring the outline. Persian weavers of the 16th century developed a successful variant in silk tapestry rugs, whereby a black outline weft was dovetailed over two warps—one of each of the adjacent colour areas—effectively hiding the coloured wefts in the compacting of the weave, and providing strong clear drawing. The same device is found several centuries earlier in Peru, but if there was a common source, examples from it have not yet been noted.

The fourth treatment—interlocking—was introduced in the Gobelins factory in the 18th century. Here wefts of juxtaposed colour-segments are looped through each other between the two warps which mark, respectively, the margin of each colour. This gives a continuous surface of even weight and was prized by the French weavers because the resultant effect more closely approximated that of painting.

Finally, one curious variant would, in strictest definition, fall outside tapestry, though it starts with the tapestry conception: between every two rows of tapestry-woven wefts is a cloth-woven, full-width shoot which makes the fabric solid. This type could be rigorously classified as a brocaded cloth, but the idea is that of tapestry, with the cloth structure subordinate and the problem solved being one in tapestry weave. The device, rare everywhere, is found in Japan in the 7th and 8th centuries, in east Persia in the 10th century (Moore Collection, Yale University), and in medieval Peru.

**High-Warp and Low-Warp.**—European tapestry may be woven on either of two types of looms, high-warp (*haute-lisse*) or low-warp (*basse-lisse*). In a primitive version of the former, the warps are attached to a beam at the top, and groups of warp threads are weighted at the bottom. The weft is beaten up toward the top. Such looms are pictured on Greek vases; the weaver shown is generally labeled Penelope and her fabled scheme of undoing the day's work at night becomes clear: she simply removed the weights and slipped the wefts off the warp threads. The more highly evolved vertical frame has heavy uprights (*bâti*, in French) holding a horizontal roller (*ensouple*) top and bottom, on which the warps are stretched. Each warp passes through a loop of cord (the *lisses*), and the loops encircling the warps which correspond to uneven numbers are fastened to one slender cylinder, those to the even, to a second cylinder, both being above the weaver but within reach so that he can pull forward with his left hand now one, now the other set of warps (*i.e.*, form the shed), in order to pass his bobbin (*broche*) behind them, this being a short, pointed, slim cylinder of polished wood on which his weft yarn is wound.

The low-warp loom, on the other hand, has the rollers on the same level at table height so that the warps stretched between them are horizontal, and the *lisses* are attached to two slats, each of which is connected with a treadle so that the weaver depresses the odd-numbered, or even-numbered series of warps to form his shed with movements of his feet, leaving both hands free to manipulate his bobbin. Production on this loom is nearly twice as fast as on the vertical loom, reducing cost proportionately. The cylinders in both instances serve to roll up the finished portion and unroll a further length of unwoven warps so that the section in process is always taut and in a convenient relation to the weaver. At both types of loom the weaver works from the back side and has a mirror into which he can look through the unwoven warps, and which is placed to reflect the portion in process; but while the high-warp weaver can examine his finished work directly by walking round to the other side of his loom, the low-warp worker has to tilt up his frame.

**Cartoons.**—The design is rendered first as a drawing on paper, the *petit patron*; then it is enlarged to the size which the tapestry is to be and is painted in exactly the correct colours on linen or,

more recently, on paper. This is called the *grand patron*. Up into the early 16th century the *patron*, or cartoon, was sometimes called in French the *portrait* (or *poutraict*). The artist specializing in designing (whether for execution in tapestry, or in other techniques and media such as embroidery, wood carving, and stained glass) was called a *portraitist*.

The full-size cartoon was sometimes itself hung as a substitute for tapestry; and large-scale paintings similarly rendered on great sheets of heavy but flexible linen, called *toiles peintes*, or "painted linens," were made expressly for this purpose. The most interesting collection of old *toiles peintes*, dating chiefly from the 16th century, belongs to the cathedral of Reims.

The high-warp weaver has the full-size cartoon which he is following hung beside him, but the low-warp worker has his laid under his warps, so he follows from immediately above his model. In both cases the main outlines are drawn with ink on the warps.

The design is executed, in all professional European work, at right angles on the loom so that in the finished hanging the warps run horizontally. This is aesthetically advantageous, since the warp ribbing tends to create a texture more or less reinforced by linear shadows, and if vertical, these sever the design, but if horizontal they bind it into continuity. Practically, however, horizontal warps are disadvantageous since they mean horizontal slits, with weight from the heavy wool fabric pulling on them as the tapestry hangs, and thus accelerating deterioration. That the aesthetic consideration should have prevailed over the practical is noteworthy.

The extra weft ends are left hanging loose on European tapestries, but they can be fixed with an additional twist and cut short, making a reversible fabric. This is a practice especially common in far eastern tapestry weaving, which is notably fine (*W'ssu* may count 60 warp threads per inch). All European tapestries are relatively coarse up to the 18th century with, in general, from 10 to 18 warps to the inch; transition from shade to shade is effected with irregular "comb-tooth" hatching.

**Twill Tapestries.**—Instead of the plain-cloth binding commonly found in tapestries, a twill can be used; *i.e.*, a weave in which the weft is floated over two or more warps, then under one or more warps, with this underpass shifted always one to the right or left making diagonal ribbing. Such a weave appears in tapestry for the first time, as far as can be determined, in Persia in a unique silk and metal-thread square, the design comprising a royal portrait, figure of angels, animals and plant motives; and from the 17th century on (Moore Collection, Yale University; Metropolitan Museum) it is used in goat's hair or wool, especially for shawls, in Khurasan and Kerman. The type is perpetuated in the well-known Kashmir shawls, and was probably introduced into Kashmir from Persia, along with other crafts, in the 16th century.

## EARLY HISTORY

**Early Examples.**—Early examples of tapestry weaving are so isolated and so fragmentary as to make it uncertain either when or where the art originated. The earliest known specimens of tapestry weaving of linen (datable between 1483 and 1411 B.C.) have been found in the favourable climate of Egypt. One bears the cartouche of Thutmose III, another of Amenhotep II, and the third, hieroglyphics; they were found in the tomb of Thutmose IV. The Amenhotep piece has the tablet bearing the king's name and titles upheld by uraei, set in a powdered pattern of lotus and papyrus flowers, with a narrow border on each side. Only the designs—in red, yellow, green, blue and brown—are tapestry-woven, the ground being plain cloth—in the tapestry areas the wefts are not kept straight, but curve to follow the drawing. A tapestry robe and part of a glove were also found in the tomb of Tutankhamen (d. c. 1350 B.C.).

At this period numerous Syrian ideas, techniques, and perhaps actual craftsmen were entering Egypt, and, since tapestry weaving does not occur again in Egypt in quantity until the 4th century A.D., it seems unlikely that the craft was indigenous.

Fragments of wool tapestries in graves on the Kerch Peninsula, of the 4th or 3rd century B.C., carry stag heads and ducks in the widely diffused Hellenistic style which was especially strong in

Syria, and about 200 to 500 years thereafter tapestry is represented again in a silk fragment, which though found at Loulan in central Turkistan has close Syrian connections. This is a band worked in seven colours (three browns, one evidently originally purple, two greens, light blue and crimson). In a central zone appears a scrolling stylized tree, in the crown of which appears a bird's head; the whole designed to present alternatively a conventional bird flanked by confronted griffins (composed of a crested bird with deer or horse feet) alternating with a symmetrical scroll. The border motive is a rosebud rendered as a heart in a deep calyx, and some of the multiple guard stripes are in continuously graduated polychromy. The bird nesting atop a cosmological tree, and the double image are both west Asiatic; fantastic griffin variations are a persistent feature of Syrian design; the heart-rose is the standard border theme on later Syrian textiles, where also compound borders with variant guard stripes are frequent, while the unusual graduated polychromy appears on approximately contemporary wool tapestries at both Palmyra and Dura-Europos. Thus this tattered strip represents the cultural linkage between the Mediterranean coast of Asia and its very heart.

The wool tapestry with graded polychromy found at Palmyra is ornamented only with groups of square dots, but that from Dura bears stylized lilies, and this figure, better drawn, appears also on wool tapestries found at Loulan which likewise may be assigned either to Syria or Persia. A closely related piece is known from south Russia. Tapestry weaving may well have been common in western Asia and especially in Syria at the start of the Christian Era; had climatic conditions been less unfavourable, a whole phase of the art now irretrievably lost might have survived.

**Egypt.**—Favourable conditions did exist, on the other hand, in Egypt, and consequently a mass of tapestry fragments has been recovered there, dating from the 4th to about the 10th century A.D.; these are especially numerous from the 5th to the 7th century and include some remarkable Coptic tapestries, exemplifying the Christian art of Egypt. These are mostly garment trimmings, woven into or (in inferior specimens) sewed onto tunics and cloaks. Tunic trimmings (*see* VESTMENTS, ECCLESIASTICAL) when complete consist of stripes over the shoulders (*clavi*) down front and back, varying in width from about 1 to 6 in., ranging in length from just below the belt to the very bottom; a neck piece; panels on the shoulders and near the knees which may be round (*orbiculus*) or rectangular (*tablion*); and cuffs. Parts of pillows also are quite common, wall hangings far less frequent, and when in solid tapestry weave—in contrast to tapestry motives inwoven in cloth—rare and proportionately important. A series of fragments formerly in Berlin representing dancers, in polychromy and silhouette, and some pillow panels, have naturalistic illustrations in a delayed Hellenistic style. Later examples are in the early Byzantine style (best examples, Dumbarton Oaks, Washington, D.C.).

The garment trimmings fall into two main classes: indigenous designs rendered either in polychromy, or more often in silhouette, most typically in some tone of purple (dyed with madder plus indigo); and designs copied, with more or less distortions, from Syrian shuttle-woven silk patterns (a distinction first established by Josef Strzygowski, and repeatedly noted by Oskar Wulff and Wolfgang Volbach). In the former, constantly recurring themes are the vine, or less often ivy; the amphora, frequently with the vine growing out of it; nude women, nude youth or boys, including dancers often armed; and animals, above all the lion and the hare—all explicable as descended from the Osiris cult and appropriate to burial robes because of their relevance to revival in a life after death. In the patterns copied from Syrian models, the styles of the different great textile-producing cities there can be recognized, and subjects from the local cults, so that, analyzed in their wider relations, they throw considerable light on the history of religion, as well as of art.

All types are woven with woolen wefts on linen warps, though a few with silk wefts have appeared, and cotton wefts are occasionally introduced to give a brighter white. Primarily in the 7th, and perhaps also the 8th century, the tapestry technique may be supplemented with embroidery, as in border margins, usually in split stitch. In a special variant, which is not true tapestry, the

characteristic meanders or other geometric repeats are executed with a free bobbin, "free" because it follows the design without regard to consistency of weft direction, carrying a linen thread which stands out on a violet wool tapestry-woven (or repp) ground. The multiplicity of tones in polychrome pieces is noteworthy especially from the 7th century on, and includes clear, delicate pastels.

Egyptian tapestry weaving deteriorated sharply from the 7th to about the 11th century, when it was somewhat improved within a very limited range. Into white (or dark green) linen garments were woven tapestry trimming bands in wool, or often in silk, occasionally with metal-thread enrichments, in groups ranging from a half-inch to a foot and more in width, with patterns of geometric enlacements, frequently enclosing small quadrupeds or birds (ducks) highly stylized, and inscriptions. Many of these merely simulate writing, but many are legible, in handsome angular Kufic scripts on earlier pieces, in cursive scripts later, giving religious phrases, or the names or titles of rulers, occasionally with the place name also (*tiraz*). A characteristic colour combination in silk is golden yellow and scarlet.

**Syria.**—From the 6th to the 8th century A.D., and doubtless from then on, striking wool tapestries were being made in Syria corresponding in style to the contemporary shuttle-woven silks with animals or birds (commonly cocks) in energetic heraldic stylization, framed in roundels, almost always on a red ground. Later, from the 11th to the 13th century, silk and gold-thread tapestries were produced in Syria, highly distinctive in style, incorporating pagan motifs that were still being used in the old Phoenician cities when the crusaders took them over.

**Persia.**—Fewer specimens of Persian tapestries have survived, but one notable fragment (Moore Collection at Yale University) bears an ibex in the impressive Sasanian style, and a single piece from the Seljuk period (11th century) establishes the maintenance of the technique. This reappears in the 16th century (intermediate examples having all apparently been destroyed) as the medium for rich silk and metal-thread rugs of which only three are known still to exist (Moore Collection, N.Y.), though others are illustrated in Persian miniatures.

The modern descendants of these, occasionally silk but more often wool, in slit tapestry, with simpler patterns, are the familiar *kilims*; and the type extends, with variations in decorative style through the Caucasus and Asia Minor into eastern Europe.

**Far East.**—Tapestry had long been in use in China, and there silk was the typical material, in a fine, light texture, the weave finished perfectly on both sides so that the panels are reversible. The warps are vertical in relation to the pattern. The "metal" thread, which is quite common, is the thinnest possible gold leaf applied to tough paper, cut in narrow strips and spirally wound on a silk core.

The earliest surviving examples, dating from the T'ang and early Sung periods (8th to 10th century), show only simple repeating patterns—flowerets, vine elements, ducks, lions—but are probably not representative of the full development of the time since they come only from remote desert stations of central Asia. Subsequent examples from the Ming period (1368–1622) are rare and exquisite. Abundant from the Ch'ing period (1644–1912), they show a severe artistic and technical decline. Especially plentiful are squares indicating rank, from official robes.

Tapestry technique traveled from China to Japan in the Ashikaga period (15th century), where it was used for characteristic muris, also in silk as a rule, and with vertical warps, but with a considerably coarser texture than Chinese work. The history of the art in Korea remains obscure, but rather coarse wool tapestry-woven rugs from there, with stylized motives, are well known in western markets.

**Western Hemisphere.**—How and when tapestry and a number of other complex Asiatic textile techniques were transmitted to the Americas is not known. Not all authorities agree that the connection took place. But examples of a fully established technique and style appear, perhaps as early as A.D. 600–700 in the Andean culture, while a vast amount of remains have come to light from the coastal cemetery sites of Peru, datable from about the 8th to

the 12th century. In the Peruvian sites, bodies were buried characteristically in a squatting posture, fully dressed, indeed often wearing a multiplicity of garments hardly feasible in life, and padded and heavily wrapped into an approximate ovoid. The principal articles are: tunics, for men, varying in length and with or without sleeves; for women, full length, or in the Incaic period, a long skirt held under the arms with a sash; for both, enveloping mantles; breechcloths for men and boys; belts; and headbands. Besides tapestry, these Peruvian remains reveal the most varied techniques of weaving and needlework ever current in a single culture. (Excellent collections: Lima Museum; Brooklyn Museum; American Museum of Natural History, N.Y.; Textile Museum, Washington, D.C.)

The warps of the tapestries are of undyed cotton (the cotton of the region being naturally either white or brown), the wefts of wool—llama, guanaco, alpaca or vicuña—with cotton sometimes introduced for bright white. The range of available colours—made with natural dyes—is large, for the most part in saturated tones; the compositions are usually polychrome and powerful contrasts are preferred. Belted looms without heddles were used.

The patterns all derive from local cults: a feline divinity, in some presentations fantastically adorned; an anthropomorphic deity (or more likely several distinct personalities) ordinarily with an elaborate headdress and frequently carrying a staff; birds, including the eagle and the condor; and fish. Plant motives are comparatively rare. All are angularly conventionalized, with the rectangle and especially the diagonal as substructure, the style showing a marked preference for meanders and reciprocals. The latter range from the most rudimentary, the serration, with its section the Z or its magnification the chevron, to complex developments of overturned interlocking figures of naturalistic origin, notably condor heads.

In the later Middle Ages, the characteristic principles of conventionalization appear: elimination—as, omission of the mouth; fusion—as, nose and mouth merged into one spot; exaggeration—as, human profile reduced to a huge nose; and part-for-whole—as, the feline represented only by its claw. The application of these devices is unusually extreme.

Though a great advantage of tapestry is its flexibility, which makes unnecessary repeating patterns, these strongly predominate in the Peruvian use of the technique in all periods. The organization of the repeats follows basic forms relevant to shuttle weaving: stripes; bands; and rectangular checks, implicit or explicit. Schemes unrelated to the fabric structure also are used: diagonal stripes, chevron stripes, lozenge checks. Within these, the succession whether of motives or of colour changes is often exceptionally complex. The usual unit is three, or its double, six—the latter a peculiarity of textile design in this region throughout its pre-Columbian history—and the permutations thereon are numerous, varied, and not infrequently remarkably ingenious.

After the Spanish conquest, European designs were supplied to highly skilled Inca weavers who executed them with their own modifications, producing an effective hybrid style (good examples, Boston Museum of Fine Arts).

Perhaps tapestry was also current in the other highly evolved pre-Columbian cultures of Central America and Mexico; but climatic conditions there have been destructive of textiles.

### EUROPEAN TAPESTRY

**Development of the Gothic Tapestry.**—References to the making of tapestries in western Europe occur throughout the Middle Ages, but the ambiguity of the term makes it impossible to be certain of the technique employed unless the object referred to has actually survived. Although the antiquity of Arras and Aubusson as tapestry-making centres is legendary, and a few rare tapestries, notably the series of panels in the cathedral of Halberstadt, Ger., are in a style that is pre-Gothic, it is only in the 14th century that the European tapestry tradition begins to emerge with any clarity. At this period the most sophisticated centres of production were in Paris and Flanders, and *tapissiers de la haute lisse* begin to be mentioned in both places in connection with the guilds. Large numbers of tapestries are recorded in inventories,

and the more luxurious standards of living being adopted by the wealthy extended their use beyond the customary wall hangings to covers for items of furniture. Survivals are rare, however, and the outstanding example is the famous Angers Apocalypse (Angers Museum, Fr.), begun in Paris in 1377 for the duke of Anjou by Nicolas Bataille, and based on cartoons by Jean Bondol of Bruges. A slightly later series (c. 1385) showing the "Nine Heroes" and possibly from the same workshop was made for the duke of Berry, and is now in The Cloisters, in New York City.

**The Low Countries.**—Tapestry manufactories are first mentioned in Arras in 1313, and Flemish centres for tapestry weaving and tapestry dealing continued to multiply during the next two centuries, with Arras, Tournai, and, eventually, Brussels emerging as the most significant names. The decline of Paris as an art centre in the 15th century left Flanders with no serious competitor in the field, and extensive patronage by the dukes of Burgundy contributed to its prominence throughout the Gothic period. Tapestry themes covered a wide range, with romances of chivalry and history predominating over religious subjects.

Local marks did not become general until the 16th century and continual intercourse between the various centres, particularly Arras and Tournai, adds to the difficulty of determining where individual tapestries were made. Despite the prestige implied in the name of Arras, only one set of tapestries is inscribed with the actual name; they have been the basis for a large number of additional attributions. They show scenes from the lives of St. Piat and St. Eleutherius and were woven entirely in wool by Pierrot Feré in 1402 for the cathedral of Tournai, where large fragments still survive. The figure style relates to manuscript painting of the same period and shows considerable character in the faces. Several decades later the same centre was probably responsible for the distinguished series of scenes from the "Passion" in the cathedral of Saragossa, where some gold has been mixed with the wool.

Production in Tournai, which is first mentioned in connection with tapestry weaving in 1352, continued to expand throughout the 15th century, and it was from Tournai that Philip the Good, duke of Burgundy, commissioned the "History of Gideon," one of the most important tapestries of the period, for his new Order of the Golden Fleece. Like many of the tapestries mentioned in the records of the period, this series has not survived, but the abundance of documentary material and the numerous names involved gives some insight into the extent of the activity. In Arras a specially designed building was erected by Philip the Good to allow for the better conservation of his numerous tapestries.

A few familiar cycles tend to be repeated: of the histories, the Alexander tapestries in the Palazzo Doria at Rome and the history of Julius Caesar in the Historical Museum at Bern are outstanding; while among the numerous hunting and pastoral tapestries of the period, the Devonshire Hunting Tapestries (now in the Victoria and Albert Museum, London) provide a fine example from the second quarter of the 15th century. A feature of the Gothic period in general was the *menues verdure* (or garden tapestries), usually referred to in the modern market as *mille-fleurs* ("thousand flowers"). These have a dark-blue ground, strewn rather sparsely with flowering plants and bushes, and usually interspersed with animals and birds. At times they are combined with human figures or armorial bearings and may even supply a background for figure compositions, as in the highly decorative "Lady with the Unicorn" series of the early 16th century in the Cluny Museum, Paris, of which the origin is still uncertain, although it seems likely to be French rather than Flemish. *Grandes verdure* (or large garden tapestries) seem to have been introduced by the Poissonier family of Tournai c. 1500, and their exoticism was inspired by Vasco da Gama's trips to the Indies; an upper border treated as a bell-fringed valance is a recurring feature. Borders in general, which were to become so important at a later date, are rare on early Gothic tapestries.

The occupation of Arras by the French in 1477, and successive sieges of Tournai in the early 16th century, contributed to the rise of Brussels, which became the dominant tapestry-making centre of the Netherlands until the general decline of the craft in the

late 18th century. From 1528 on it was obligatory to weave the Brussels city mark—an escutcheon flanked by B's—in the selvage, and the shopmark also was usually inserted. The patronage of the emperor Charles V and the skill of the Pannemaker family, the most accomplished weavers in Brussels throughout the greater part of the 16th century, combined to establish the reputation of Brussels. Fine tapestries from this centre are dispersed throughout the museums and collections of the world, the Austrian State collection (Kunsthistorisches Museum, Vienna) being particularly rich.

Two new trends became apparent at this period. The first, brought about by war and persecution in Flanders, resulted in the widespread diffusion of the Flemish art of tapestry weaving. Many Flemish artisans in the 16th century were forced to become refugees: some grouped together to live the life of traveling craftsmen; others attempted to reestablish their trade abroad. Flemish weavers were welcomed everywhere as carriers of a great tradition. Such itinerant masters established more or less enduring shops from England to Italy. The second important new trend emanated from Italy and reflected the superiority attached by the Italian Renaissance to the art of painting. The decisive step, which was to bring about the subordination of weaving to painting for more than 400 years in the art of tapestry, was taken when Pope Leo X commissioned Pieter van Aelst of Brussels to weave a series of tapestries illustrating the "Acts of the Apostles" from cartoons produced by Raphael between 1514 and 1516. Little or no concession had been made to the medium for which the cartoons were intended, but the tapestries were a great success, and numerous copies have subsequently been made.

Qualities introduced during the Renaissance were pushed even farther in the 17th century, when the dominant influence in the Brussels industry was Rubens (1577–1640). His most famous set was the "Triumph of the Eucharist," designed (1627–28) to the order of Archduchess Isabella of Spain, but imitations and adaptations of his style were legion. Heavy and elaborate columns were often substituted for side borders. On a more modest scale are the tapestry versions of genre paintings by Teniers, the younger (1610–90), where the border frequently simulated the actual picture frame.

**France.**—French tapestry weaving, after its eclipse in the 15th century, when nomadic weavers seem to have been more active than established shops, owes much of its eventual prestige to an unusual degree of royal patronage, resulting in the foundation of state shops, the names of which have now become household words. A prelude to this development was the factory established at Fontainebleau by Francis I in 1538. Although active for only 12 years and by no means an indigenous art in the first place (its masterpieces are by Flemish weavers from designs by the Italian painter Primaticcio), it provided a springboard for subsequent developments in Paris, where in 1551 Henry II established and endowed with special privileges the Hôpital de la Trinité workshop. Although workshops multiplied, results were at first disappointing. And it was due to the initiative of Henry IV, whose planning of his nation's economy emphasized the luxury production that has since been industrially important in France, that decisive steps forward were taken. In 1608 Henry IV gave official recognition to the French workshop (using the high-warp method) of Girard Laurent and Dubout by establishing them in the Louvre, and at the same time he encouraged the immigration of Flemish weavers practising the low-warp method, who would help Paris to compete with the flourishing industries of Brussels and Antwerp.

**Gobelins.**—At turn of the 16th–17th centuries, two Flemish weavers had been taken to France by government arrangement to establish *basse-lisse* looms (*de la marche*) in Paris: François de la Planche (or Franz van den Planken) and Marc Comans. Satisfactory working conditions were found for them in an old dye factory on the outskirts of the city which belonged to the Gobelin family, and so began the establishment commonly known by that name, which has lasted ever since. One of its first ambitious productions was an allegorical invention lauding Catherine de Médicis under the guise of Artemisia; for this the *petits patrons* were chiefly by Antoine Caron (c. 1515–1593); but the shop's most

valuable asset was Rubens' "History of Constantine," and it was the verve and vitality of Rubens that brought new life to French designs at this period.

De la Planche died in 1627 and was succeeded by his son who broke with the Comans family and moved to the *faubourg St Germain-des-Près*, leaving the Comans at the Gobelins. Competition became bitter, but both continued to produce a considerable quantity, as well as good quality, until they were superseded in 1662 by the royal factory, which purchased the Gobelins workshop as its seat.

Louis XIV's minister, Colbert, alert to profitable possibilities, recruited skilled personnel, not only from the de la Planche and Comans shops, but also from the old Louvre enterprise, and thus established ateliers of both horizontal and vertical looms. As director, he utilized Charles Le Brun (1619–1690), already experienced with tapestry in a brief-lived undertaking by Colbert's ill-fated predecessor, Nicolas Fouquet; the Gobelins shops were officially chartered as a royal factory in 1667. Le Brun designed the most important sets, the "Elements," the "Seasons," and above all, the "Life of Louis XIV," supplemented by the "Royal Residences," 37 large panels altogether. Le Brun's triumphant academicism dominated the work of Antoine and Charles Coppel (1661–1722, 1694–1752), and a half-dozen other designers who devoted themselves to classical and Biblical themes; a lighter spirit was introduced by Claude Audran the Younger (1637–1734), with his talent for decorative inventions, especially grotesques.

Louis XV (1710–1774), in his turn, was celebrated in a set of "Hunts" by Jean Baptiste Oudry (1686–1755). But the outstanding artist working for the factory during this reign was François Boucher (1703–1770), whose sophistication and polished elegance posed new problems for the weavers. Now indeed they must learn to paint with a bobbin, and to this end hundreds of new dyes were perfected for both wool and silk, until about 10,000 hues were available, to effect almost imperceptible tonal modulations; and interlocking of the wefts was introduced to render the transition practically invisible, while the finest textures practical were used, from 20 to occasionally as many as 40 warps to the inch.

**Beauvais.**—Both Oudry and Boucher worked also for another major state-subsidized factory which had been carried on at Beauvais by two Flemings, Louis Himart, for 20 years (1664–1684) and Philippe Béhagle for 27 more (1684–1711). Oudry made for it his famous "Fables de La Fontaine." Boucher in 1736 began to purvey Italian fêtes, Chinese scenes and various pastoral scenes with titillating overtones. The factory has been especially noted for furniture and screen panels. Beauvais tapestries were executed primarily by the low-warp method.

Two new types of decorative panels appear at the height of production, the architectural composition and the grotesque. The former usually shows a complex arcade with massive balustrade on which stand urns of flowers and perhaps a bird or two, as a peacock with trailing tail. In the latter, architectural tracery defines a complex of panels, framing a medley of festoons, scarves, vases, musical instruments, *putti*, masks and comedy actors. For the English taste, entire wall coverings were made at the Gobelins factory, much larger than, but stylistically like, these decorative panels.

By the end of the century, though technical standards were maintained, artistic deterioration set in.

**Aubusson.**—A third factory at the old-tapestry-making centre of Aubusson, which had operated as a modest private undertaking for a century and a half, was chartered as a royal factory in 1665, but practically all the output there was relatively coarse material for the open market. The most effective pieces are *chinoiseries*. Coarse, rather dull, verdure were made in quantities. Aubusson architectural panels either imitate those of the greater ateliers, or often with more complex elements and the addition of animals, or depict a damasked wall hung with a painting or cluster of decorative objects, and garlands. The factory was especially successful in its production of carpets, with conventional or floral designs.

In all three shops the idea of tapestry as a woven picture was so predominant that the commonest border was a woven imitation of a carved and gilt frame.

Apprentices in these factories, in order to attain the rank of master, had to produce a small specimen of their work with a difficult subject. Sometimes an elaborate vase of flowers was chosen, but often copies were made of paintings in the royal collection, and similar little pieces were made by the weavers in their own time to supplement their income.

**Italy.**—Itinerant Flemish and French weavers, setting up their looms in cities where there was temporary employment, brought tapestry weaving to Italy as early as the 15th century. First to establish a workshop was Leonello d'Este who brought Rinaldo di Gualtieri Boteram to Ferrara from Brussels. The second major factory, the Arazzeria Medici, was founded by Cosimo I in 1546. He began with two Flemish weavers from Ferrara, Nicholas Karcher and Jan Rost. The latter became the outstanding tapestry weaver in Italy. His signature on the tapestries is symbolized in a pun on his name—a chicken roasting on a spit. Well-known painters provided cartoons; e.g., Bronzino, Alessandro Allori, Francesco Salviati. A noteworthy series of genre scenes was woven in 1639 from earlier designs by Francesco Ubertini. The Medici looms continued until the death of Giovan Gastone, the last Medici grand duke of Tuscany, in 1737.

**Spain.**—Flemish tapestries came in great quantity to the churches and palaces of Spain during the 15th century; to repair and care for them, Flemish weavers were brought in. Later, one of these, Frans Tons, established the factory of Pastrana during the reign of Philip IV. Another weaver, Jacob van der Goten, was commissioned by Philip V to start the factory of Santa Bárbara near Madrid in 1720. Long active, the great contribution of this factory was the production from 1776 to 1791 of 45 tapestries from brilliant cartoons by Goya. The factory was closed in 1835.

**Germany and Switzerland.**—Early Gothic tapestries were made in considerable numbers in southwest Germany, and hangings in a pre-Gothic style survive in the cathedrals of Halberstadt and Quedlinburg, but the craft remained closer to folk art than in Flanders or France. The tapestries are for the most part traditionally long, narrow strips, modest panels or cushion covers, coarse in texture, simple in shading, limited in palette, but with clear strong colours effectively contrasted. Doll-like figures, monsters half fairy tale and half heraldry, undulant banderoles with naïve explanations in bold Gothic lettering, scrolling foliation, and stiff flowerets often combined with patterned backgrounds to give a toyland charm.

This domestic type continued into the 17th century, but in addition, various shops were established for longer or shorter periods by wandering Flemings, who usually failed to equal the home-country style. A more sophisticated style eventually prevailed, when factories employing immigrant weavers were established in Berlin, Munich, Würzburg, and Dresden.

**Scandinavia.**—In Norway, fragments of tapestry with traces of human figures and trees have been found in the Oseberg Ship of the early 9th century. A more complete tapestry, found between two floors of the old church of Baldishol (Hedemark), can be dated around the end of the 12th century. Identifiable figures on it are two of the months of the year, April as a bird-catcher and May a mounted knight, each framed in an arch. The background had a decorative pattern; there is sharp, contrasting colour in the figures, and the colour areas are dovetailed.

Of the nearly 1,300 registered Norwegian tapestries, approximately 1,250 originated in the small rural communities; Norwegian tapestries may be considered a folk, or a provincial, art.

In Sweden there is no evidence of tapestry production before the middle of the 16th century when King Gustavus I introduced some Flemish weavers. The 18th century produced small coarsely woven panels, patterned with flowers and birds, attractive as a peasant craft.

**England.**—The major textile art in England was embroidery; when tapestries were needed, they were imported from Flanders. Their popularity can be judged, however, by the fact that inventories drawn up after the death of Henry VIII in 1547 show that the royal collection then comprised more than 2,000 tapestries, many of which had been confiscated by the crown on the dissolution of the monasteries.

Although references to Arras weavers in England occur off and on from the 13th century, and a few armorial tapestries have survived from the 15th century, it is not until the 16th century that tapestries from an established English manufactory can be securely identified. At this period tapestry workshops were set up by William Sheldon (d. 1570), producing mostly small panels and cushion covers. A later specialty of these shops was a series of topographic tapestries, woven in 1588 from contemporary maps of Midland counties, which featured bird's-eye views of hills, trees and towns, surrounded, according to the custom of the period, by Flemish-styled borders of architectural and figural ornament.

In 1619 a factory of tapestry weaving was established by royal charter at Mortlake near London. The director, Sir Francis Crane, enticed about 50 Flemings to settle in England with their families. Philip de Maecht came from Paris, where he had been a leading *tapisier*, to be overseer and master weaver. The Mortlake factory flourished under the patronage of James I and Charles I. Rubens supplied cartoons and suggested to Prince Charles the purchase of the Raphael cartoons of the "Acts of the Apostles"; Van Dyck designed new borders for these. But, under Charles II, the factory's last years showed sorry deterioration; it was finally closed in 1703.

From the end of the 17th century, the Poyntz brothers had a studio in Soho, where a number of former Mortlake artisans eventually produced a distinct style based on Chinese and Indian lacquerwork.

**Russia.**—Peter the Great, as part of his program of modernizing his country, established looms in his capital in 1716, with workers from the Gobelins. The most striking productions are portraits of Catherine the Great. (P. AN.; D. W. LI.; X.)

## MODERN DESIGN IN TAPESTRY

During the main portion of the 19th century, in tapestry as in other luxury arts past styles were reproduced as closely as possible. The influence of industrialization was inescapable, of course, not only in tools, materials, and dyes, but in the new middle-class market and its demands. Machine-made tapestry, although an achievement in mechanical weaving, became a threat to the survival of the original craft.

In England programmatic designers saw the necessity for the revival and purification of craftsmanship; and in 1881 William Morris established a tapestry factory at Merton Abbey in Surrey. For about 15 years he and his associates had been designing not only for looms but also for pictorial wall decorations and stained glass windows; they were well prepared professionally to design tapestries. Morris and Walter Crane (1845–1915) contributed sketches, but most Merton tapestries were designed by the painter Sir Edward Burne-Jones (1833–98). More venturesome than any of the Merton Abbey products were the tapestry designs made in the 1880s by Arthur Heygate Mackmurdo (1851–1942), who in 1882 founded the Century Guild, the first of many groups of artists-craftsmen-designers to follow the teachings of William Morris. This tradition, influenced by more contemporary French developments, is continued in Scotland by the Edinburgh Tapestry Company and the Golden Targe Tapestry Studio, along with some others. The most ambitious 20th-century tapestry designed by a British artist, Graham Sutherland's enormous "Christ of the Apocalypse" (1962) for Coventry Cathedral, was, however, woven on Aubusson-Felletin looms in France (the largest tapestry ever to have been made there).

Elsewhere, from the late 19th century onward, there has been a resurgence of tapestry based on folk traditions. In Scandinavia this trend was already apparent in Norway shortly after 1890, when special efforts were made to base a modern tapestry art on native medieval weavings. The leaders were Gerhard Munthe (1849–1929), a well-known painter, and Frida Hansen (1855–1931), a weaver who studied the peasant craftsmanship of Norway and evolved an individual, light and open weave. More recent developments in Scandinavia have been made in Sweden and Finland. Marta Måås-Fjetterström (d. 1941) is the best-known Swedish tapestry artist, and her atelier continued to produce excellent works. In Finland a freer, more colourful art, more deli-

cately scaled, has been practised by many; among the best-known are Martta Taipale, Laila Karttunen, and (for damask tapestry) Dora Jung. In Norway and to a lesser degree in Denmark similar work has been done. The church in the Scandinavian countries has been unusually receptive to this art. Traditional folk weaving has also been behind the revival of tapestry-making in Poland, Czechoslovakia, and Hungary since World War I; Poland especially has produced original designs executed in a remarkably free technique. In the Western Hemisphere folkcrafts, including Mexican tapestry weaving, have been revived throughout Latin America with varying degrees of success.

Germany, emulating Scandinavia, also began a revival of tapestry weaving around the turn of the century. A small tapestry industry set up at Scherrebek, near the Danish border of that day, from 1896 to 1903 was followed by similar enterprises at Kiel and Meldorf. The most significant development, however, was at the Bauhaus (q.v.) where a branch of modern tapestry design was developed during the 1920s and early 1930s, abstract in composition, and profoundly rooted in the loom technique and in the exploitation of fibres as strong textural elements. Anni Albers, long a resident and teacher in the United States, may be considered the chief practitioner of this kind of tapestry (more often restricted in size). She was the first weaver to receive the accolade of a one-man show at the Museum of Modern Art, New York, and like most modern tapestry weavers, she also designed for the textile industry.

Modern tapestry design was hindered during the greater part of the 19th century in France by the academic administration of the state factories, although progressive artists began to be affected by the English Arts and Crafts movement in the later 1880s. Gauguin (1848-1903), Émile Bernard (1868-1941), Paul Ranson (1862-1909), and the young Aristide Maillol (1861-1944) were among those who took an interest in and designed specially for tapestry weaving. But it was not until after World War I that French tapestry took the lead in a double way. The great modern painters of the day—Picasso, Braque, Matisse, Léger, Roualt, Miró, and others—permitted their works to be reproduced with extraordinary fidelity under the supervision of Mme Marie Cuttoli, a Paris connoisseur and promoter of exceptional taste. Aubusson, chosen for this important weaving, became once again a great tapestry centre. The direct translation of painting into tapestry, however, left little scope for the weaver, and it is the trend begun simultaneously by Jean Lurçat (1892-1966) that may be said to have truly inaugurated the 20th-century tapestry renaissance. Although he was experimenting since 1916, Lurçat's art did not become definitive until the 1930s, when under the impact of Gothic tapestry (particularly the Angers Apocalypse) and in collaboration with François Tabard, master-weaver at Aubusson, he formulated the principles that were to make tapestry once again a joint creation between artist and weaver, an art in its own right. No longer merely an imitation painting, tapestry once again exploits the coarser texture and the bolder but more limited range of colours that characterized the medieval work. Since World War II tapestries of Aubusson have become world-famous, and the enterprise has attracted many artists working primarily for this medium. They include Marcel Gromaire (b. 1892), Lucien Coutaud (b. 1904), and Jacques Lagrange (b. 1917).

**TAPEWORM**, a parasitic flatworm lacking both a mouth and a digestive system; as an adult it clings to the intestinal wall of a variety of vertebrates, moves about in the intestinal contents, matures, mates, and produces eggs before it passes out of the host's body. Tapeworms constitute a class, Cestoidea or Cestoda, of the phylum Platyhelminthes. Their life cycles are complex and usually involve one or more intermediate hosts during the various larval stages. In a few cases the adult may be a single flattened individual, but in most species it consists of a ribbonlike body (strobila), usually white or yellowish, of many segments (proglottids) that are budded off behind an anterior holdfast organ called the scolex. The number of proglottids varies from three or four in some species to several hundred in others, and the length of the strobila from less than a millimetre ( $\frac{1}{32}$  in.) to more than nine metres (about 30 ft.). With few exceptions each proglottid and unsegmented individual contains both male and female reproductive systems. In primitive tapeworms, as those of sharks, the proglottids detach from the strobila before the sex organs are mature; thus, each proglottid behaves as if it were an individual. In more highly evolved forms, as the tapeworms of man, this individuality is lost.
